We are here in this article, only concerned with a statistical review of the sugar industry in India; the economic portion being reserved for a subsequent paper. We thus find that in regard to outturn, the Government of India do not place much reliance on the figures received by them from the several Local Governments and Administrations, and which have been submitted by them to the Secretary of State for India. The figures are avowedly estimates of average yield, which depends not only on soil and climate, but on the character and thoroughness of the cultivation; and the discrepancies apparent in the estimates furnished by the several Local Governments are thus accounted for. For instance, in the North-Western Provinces, where considerable attention is paid to agricultural statistics, the estimated yield in the several districts was variously returned between 15 and 22 cwts. of sugar per acre; for the Punjab a single estimate of 19 cwts. 1 qr. was furnished; while in Bengal, where it is estimated in molasses, the average varied from 6 to 32 cwts.; and from 2 to 28 cwts. when computed in sugar. In the Central Provinces again, the average was actually set down as low as 4½ cwts. But this was thought to be much below the mark. The Bombay Presidency alone presents anything like a uniform average, viz., 19 cwts. per acre of sugar, although the district returns were said to be as conflicting as those for Bengal. The explanatory notes, however, which accompanied the figures for the various provinces, showed that the statistics of produce were to be received with caution; while those in the case of Bombay furnished strong evidence that the statistics of produce supplied by the village officers were much under the real truth. Owing to the various ways in which raw produce is disposed of, it was found exceptionally difficult to obtain satisfactory estimates in the case of sugar cultivation. The marked discrepancies observable in this connection may be explained to some extent by the fact that the greater portion of the sugar produced in India never goes beyond the unrefined state; and in estimating the average produce, it is usual to refer to sugar of this class, except in cases where the estimates are extremely low, when the outturn in refined sugar has been taken.

(To be continued.)

THE DISTRESS IN BURDWAN.

A CORRESPONDENT of the *Indian Mirror*, writing on the scarcity prevailing in the Burdwan district, says that, owing to the increased number of applications for relief, the means at the disposal of the Committee formed in Burdwan, are fast ebbing away, and appeals, under the circumstances, to the "rich and generous of this country, in the earnest hope that they will kindly come forward to rescue from starvation and death, thousands of fellow-human beings who are at present plunged by a dreadful visitation of Providence into the most intense sufferings." As some persons, to whom applications for aid were made, refused, on the ground that they "had already sent contributions to the district officer, who is the proper person to distribute charitable relief in his district," it is explained that the Committee, who are composed of the leading gentlemen of the town of Burdwan, have been distributing aid principally through the officers of the Government, who have been employed specially upon relief work. The rule of Government limits the supply of Government relief either to persons who are willing to work upon Government roads, or to persons who have no objection to partake of cooked food. There is no fund for the relief of people who, by reason of their caste or social position, are precluded from availing themselves of either of the aforesaid two modes of relief. The fund at the disposal of the Committee is intended for these people; and the Government relief officers being on the spot, are best able to ascertain the cases in which the pecuniary aid in the gift of the Committee can, with advantage and propriety, be applied. The Committee, in certain cases, send money for distribution by the hands of respectable gentlemen, who go round from village to village administering

relief to deserving cases. The accounts, which are brought in by these gentlemen of the depth of suffering and destitution to which the majority of people of many villages have been unfortunately reduced, are touching in the extreme. Hundreds of people are eager candidates even for the one-half pice a day, at which rate the limited means at the disposal of the Committee now enable them to dispense relief. The total amount, now in the hands of the Secretary, is only Rs. 1,100, and considering the distress, is sure to be intensified during the next three or four months, and that the number of people standing in need of relief must be considerably more than at present, it is quite clear that the aforesaid amount can last but for a short time more only. We earnestly commend the appeal made by our contemporary, to all our readers who have the means of helping the sufferers in this extremity. Our own belief is absolute, and has ever been so, that in the absence of a poor law in India, the Government itself should furnish all the funds required in these extremities, imposing if necessary a casual tax for the purpose. We cannot wait however to press these counsels on the State, but urge all who have the means to contribute at once to the failing funds of the Committee.

THE LONDON EXHIBITION.

A RESOLUTION of the Bengal Government, published in the supplement to the *Calcutta Gazette* of the 13th instant, suggests the preliminary questions for a Committee appointed by the Lieutenant-Governor, to consider the best means of concerting measures to represent the Bengal Presidency at the London Exhibition of 1886. A sum of Rs. 20,000 will be placed at the disposal of the committee for this purpose, whose duties will be confined to the equipment of the Provincial Court, illustrating art ware, ornamental fabrics, and decorative work of Bengal, and to the executive duty of receiving and forwarding either to the Government of India, or to the Royal Commission, applications for space by private exhibitors resident within the province. In view, however, of lightening the burthen upon the Provincial finances, it has been decided to utilize the exhibits for the London Exhibition at the Bombay Exhibition of 1887, without making any special collection of fresh ones, or a separate allotment of funds. Should any of the exhibits be sold in London, duplicates will be prepared for Bombay. Apart from the articles to be collected locally, the chief ornament of the Bengal Court will consist of screens, showing the characteristic styles of Bengal architecture, or the features and peculiarities of the decorative arts of the country. For this purpose, a separate grant of Rs. 1,500 has been sanctioned, which, if insufficient, may be increased by taking from the grant of Rs. 20,000, should the Committee think necessary. According to the recent Resolution defining the functions of the Agricultural Department of Bengal, the organization of such exhibitions would form one of the duties of the Director; but in the present instance, the pressure of work, necessarily accompanying the formation of a new department, will render it impossible for him to undertake these duties without assistance, hence the appointment of a Committee consisting of ten members (with whom the Director is associated), with Mr. H. A. Cockerell as President, was found to be necessary. The President is to arrange to hold a meeting as early as possible, to decide all preliminary questions, and to start work throughout Bengal, as all articles for exhibition must be ready for despatch by the 25th December 1885.

TRADE BETWEEN RUSSIA AND CHINA.

The following very interesting article appears in a Russian paper called the *Journal of the Ministry of Finance*, which gives a fairly accurate idea of the conditions of trade between the two countries. The information is said to be derived from the most recent sources:—

"That State, including all its dependencies, covers an area of 10½ millions square versts. The 15 provinces forming what is called China Proper embrace no more than three million versts of this surface, and their population is 352,000,000 inhabitants, while that of the whole empire reaches to about 382,000,000. As a matter of fact, almost the whole commercial and industrial life of the Empire is contained in the thickly-peopled provinces which are close to the sea; the provinces near our possessions on the Amour and in Siberia, or stretching into the interior of Asia, do not enjoy as favourable a situation. The southern province of Manchuria contains 3,000,000 persons; the Mongolian steppe, 2,000,000 nomads; Kashgar and Kaidja have been almost depopulated during the recent wars. Tibet has 6,000,000 inhabitants, and Corea 8,000,000. The seaports of China provide a residence for 4,000 Europeans; and there are about 340 foreign mercantile firms, of which more than

half are located at Shanghai. At Khabk and Tientain there are eight Russian houses engaged in the tea trade and in the preparations of brick tea. Along the northern coasts of the Empire as well as in Kuldja, Kashgar, Chuguchak, and Ourga, a few Siberian merchants may be met with.

"Industry, although essentially different from that of Europe, is extremely flourishing throughout the whole of Central China. The methods still in use are those that were employed 2,500 years ago. The use of machines and other technical appliances is altogether unknown; small farms form the bulk of the agricultural distribution; each plot of land is manured like a kitchen garden. Vegetables are generally cultivated, as also are rice, wheat, and barley. Tea, cotton, silk, and sugar represent important articles of commerce. Industry yields place, however, to agriculture although manufactures—silks, porcelain, various kinds of carved wood works as well as mats enjoy generally a high reputation. The neighbouring countries of China, properly speaking, are distinctly behindhand in point of industrial prosperity. With regard to the state of revenue, it is difficult to ascertain the exact amount in a country where the Governor of each province raises what he wishes or what he can, and expends much on local requirements. The revenue actually sent to Peking would not amount to more than 75,000,000 roubles. By assuming the total receipts to be double that sum, it would be found that agriculture alone contributed about 60,000,000. We know exactly the amount of the customs received from the 22 seaports open to foreign trade. In 1864 these exceeded 13,000,000 roubles; to day, they are about 25,000,000. The expenditure is only known with little exactness. It is supposed that the sum annually spent on the army amounted to 100,000,000 roubles, while that on canals reached the sum of 8,000,000. In order to cover the deficits which had arisen recourse was had to a foreign loan in 1874 on the guarantee of the customs. The internal commerce is carried on chiefly by water-routes. Many thousands of boats are employed in navigating the rivers and canals. There are also numerous carriage roads, the best of which, crossing the Thian Shan range, connects China Proper with Kuldja and Kashgar. With regard to the commerce between Russia and China, it is carried on both by land and by sea. Within the last five or six years the sea traffic has increased owing to the efforts of the patriotic fleet. In 1882, 245,000 poods of tea were transported to Moscow by way of Odessa. The land trade passes for the most part through Kiachta. After describing the different treaties concluded between Russia and China, within the last 200 years, the *Journal* states that, whereas in 1800 Russia only received 80,000 poods of tea per annum, in 1855 the amount had risen to 225,000 poods, and in 1883 it was not less than 913,000 poods. With regard to Russian exports into China, there has, on the other hand, been a great falling off. In 1855 the exports amounted to 6½ million roubles; while in 1881-3 they had fallen as low as 2½ millions. Trade with China presents great difficulties. The Government is obliged to come to the help of our merchants. It is with this object that more than one expedition into the Celestial Empire has been sanctioned, that new Consulates have been established, that the routes, in the border provinces have been improved, and that shorter routes have been sought for. It is with the same object that quite recently credit establishments have been opened at both Tashkent and Vernoe."

THE RUMOURED INCREASE OF THE DUTY ON TEA.

We publish below the representation recently addressed by the Indian Tea Districts Association to the Chancellor of the Exchequer, on the subject of the rumoured increase of Tea duty, and of the reply that has been received.

THE INDIAN TEA DISTRICTS ASSOCIATION.

To the Right Hon. C. E. Childers, M. P., Chancellor of the Exchequer, &c., &c.

SIR,—The rumour that the increase of the duty on Tea may form part of the impending fiscal adjustments of her Majesty's treasury, has produced a feeling of uneasiness and anxiety on the part of those interested in the growth of tea in her Majesty's Indian Dominions. While the Association trust that there is no truth in this rumour, they nevertheless feel it necessary to offer a respectful remonstrance against a step so prejudicial to the interests of the Industry they represent.

The existing duty of 6d. per pound amounts to over 70 per cent of the market value of the teas imported from all countries, and constitutes a distinctively onerous tax on a commodity of such universal consumption in this country as to be justly regarded as one of the prime dietary necessities of life.

To further enhance that rate cannot fail to entail considerable hardship on a large section of the community already suffering from the effects of industrial depression and diminished earnings. It must also tend (more especially under these conditions) to restrict consumption, and thereby partially defeat the object aimed at.

The effect of the increased duty upon the Indian Tea Industry, there is every reason to apprehend will be seriously detrimental. That industry has been for a long time past in a depressed condition, requiring great energy, perseverance, and economy on the part of those interested to maintain the enterprise and prevent a collapse.

The Indian Tea Industry has now attained to large dimensions, representing an investment of capital little short of 16 millions sterling, and contributing during the past year 67 million pounds of Tea to the imports of this country, and upwards of 1½ millions sterling to the Revenue. It has been the means of bringing under cultivation immense tracts of land hitherto unproductive; affording well paid employment to a vast number of labourers, and diffusing

a most beneficial influence on the general well-being of the people, as well as adding substantially to the revenue of the Government in the districts in which it is prosecuted.

As a matter of fact Tea already pays an enormous duty, equal, in the case of at least a moiety of the import, to as much as the prime cost of the articles.

It certainly seems to be an anomaly in our system of taxation that a pound of tea from Free trade India, valued at 12 pence in Bond, should be taxed at 6d, and that a bottle of Champagne from Protectionist France valued at 5 shillings in Bond, should be taxed only 2 pence.

The effect of any increase of duty would be that the poorer classes of the community, being unable to pay more than they do at present, would have to be content with an inferior article, and as the inferior qualities are largely produced elsewhere, the sale of the produce of India would be seriously prejudiced.

Looking to the importance of encouraging to the utmost the great efforts which are being made to promote habits of thrift and temperance among the people, any measure calculated to curtail the consumption of tea would undoubtedly tend in a great measure to neutralise those efforts, and on this ground also is greatly to be deprecated.

We would further submit that in view of the fact that British manufactures are now allowed to enter India duty free, it is manifestly unfair that the mother-country should impose further burdens on the products of her great Dependency.

On behalf of the Indian Tea Districts Association,

(Signed) T. DOUGLAS FORSYTH, Chairman,

EARNEST TYE, Secretary.

March 18, 1885.

Treasury Chambers, WHITEHALL, S.W., 27th March, 1885.

SIR,—I am desired by the Chancellor of the Exchequer to acknowledge the receipt of your letter of the 18th instant on the subject of the Tea Duty, but he feels sure that your Association will not expect him to discuss rumours in the press with reference to the forthcoming Budget.—I remain, Sir, your obedient servant,

J. M. CARMICHAEL.

Sir T. Douglas Forsyth, K. C. S. I., C. B.

Miscellaneous Items.

THE heavy rainfall prevented the annual Simla outing to the Sipt Fair.

Foot-and-mouth disease has broken out amongst the siege-train bullocks at Ferozepore.

THE Saharunpore Horse Show for 1885-86 will be held on the 23rd, 24th, and 25th February 1886.

DURING the month of March last, there were 143,491 births registered in the North-Western Provinces and Oudh.

WE understand that Mr. G. M. Barton has been appointed Provisional Secretary to the Chamber of Commerce, in place of Mr. Rutherford, deceased.

THE Conservator of Forests, Bengal, has been appointed an *ex-officio* member of the Central Examination Committee, Calcutta.

THE weather at Simla, we hear, is quite abnormal—rain falling constantly, as though the *chota bura* had set in before its time.

THERE has been very heavy rain at the Himalayan settlements during the past week, especially in the neighbourhood of Simla and Mussoorie.

THE Government has sanctioned the expenditure of Rs. 826, for constructing a permanent shed for the blacksmithing branch of the Madras Industrial School.

UNSETTLED weather prevails throughout the Punjab accompanied with rain. It is likely to cause much damage to the wheat crops, which are being winnowed.

THE weather in Nepal of late has become cooler and more seasonable, and 2-86 inches of rain have fallen. The prospects of the crops, however, continue only moderate.

THE *Gujarat* says that his Highness the Maharaja of Baroda spent about a lakh of rupees for charitable purposes on the occasion of the death of his wife Chinnabai.

ACCORDING to a Simla correspondent, Mr. Ney Elias, accompanied by Mr. Carey, the Salt Commissioner, starts shortly for Ladakh. Mr. Carey will make for Yarkund.

LIGHT showers of rain fell at Pondicherry on Monday night and Tuesday morning, last week, and appearances indicate a further fall. Vegetation sadly requires rain, and the tanks are fast getting dry.

THE increase of low fever at Poona is attributed by a local paper to the extension of sugar-cane cultivation, which had led to a good deal of land in the neighbourhood being turned into swamps.

CHOLERA of a virulent type has broken out at Nasick. During the past fortnight, 75 persons have been attacked and 45 have died. The authorities are doing their best to stamp out the disease.

THE revised estimate, amounting to Rs. 91,000, for diversion of the Buckingham canal from Gromandel to Thattupet, is sanctioned in supersession of the estimate of Rs. 98,000 included in the completion estimates of that canal.

MR. H. S. THOMAS, First Member of the Board of Revenue, Madras, is shortly going to Tanjore to make a local inquiry and report upon the claims of the ryots of that district for remissions consequent on the adverse season of the last year.

MR. HARBURN, a coffee planter of the Kador district, has contributed the skin of a huge rock snake, a two-headed fish, and a bird of paradise to the Mysore Government Museum, where these curiosities may be now seen by visitors.

THE mortality returns for the month of March show that the total deaths from all causes aggregated 82,841, compared with 71,809 in the previous month, and 121,099 in March of last year. Fever of sorts accounted for the deaths of 67,359 persons.

THE inhabitants of several villages in the Kolapore Collectorate were startled on the night of the 29th ultimo between the hours of ten and eleven by a slight shock of earthquake, which at its most extreme vibrations had the effect of shaking the tiles off several buildings.

THE latest news from the tea districts is that rain has been generally plentiful, but a higher temperature is wanted in many parts to bring out the flushes. The many hailstorms that have occurred in Coohar have not done much damage, except to a few gardens.

THE *Madras Times* says:—The expected flat for reductions has come from the Government of India, at least so far as regards the Irrigation Branch of the P.W.D., where orders were received lately for a curtailment of expenditure by two lakhs of rupees in the current year's Budget allotment.

THE water famine is at its height in Bangalore. The population of the town, especially in Mamulpatta and Siddioutta, are put to very great straits for a daily supply of water, and have to travel out to great distances to obtain the fluid. The authorities have not devised any efficacious remedy.

IT has been definitely ruled that the inspectorships and other subordinate appointments under the new Exolise arrangements are to be conferred exclusively upon the natives of the country. The Commissioner of Pegu strongly recommends that good Burmans from the ranks of the police force be selected for the posts.

AT the annual festival held at Mangalagiri, Guntur taluk, Kistna district, held on the 21st February to 3rd March, there were about 8,000 pilgrims present. Three cases of injury were taken to the hospital sheds, two of them resulting from the wheel of the car passing over the patients' legs, and which necessitated amputations.

THERE are several farms at Mangierle, belonging to and worked by East Indians. They are in a flourishing condition, and are considered profitable investments by the owners. It is a matter of some surprise, that some more pensioners do not purchase and work land, thereby diverting the ambition of the rising generation from everlasting desk-work.

THE Secretary of State has wired that the New South Wales Government has offered its services in procuring supplies of preserved meats, live-stock, cattle and horses. All Local Governments and Army Departments have accordingly been directed to resort to the Colonies, where stores or supplies can be procured as cheaply and as expeditiously as from England.

A CORRESPONDENT writing to a contemporary from Gwadar on the 2nd instant, says:—"Reports from the interior show that much damage has been done to property by floods and the overflowing of the river Ketchi Kowe. Some fifteen lives have been lost, and the villages of Haligby and Syob have been washed away. It is said that about 20,000 date trees have been blown down."

INCENDIARISM is very frequent during these hot months. But it seems strange that in Government offices and establishments which are well guarded, it should prevail. Some time ago the settlement records in the Collector's office were burnt, and on Friday last, the 1st instant, the Money Order and Registration branches of the Post Office at Sikraul caught fire, and nearly all the records were destroyed.

THE Economic Garden at Hyderabad Sind bil's fair to become self-supporting in a year or two. It produces splendid grape, and our Hyderabad correspondent informs us that its fruit has been recently sold for Rs. 3,000 to Devji, a Kurrachee contractor. The vegetables produce about Rs. 1,000 or 1,500. The cost of the Garden is Rs. 6,000. It has been very much improved of late, and is well worth a visit.

A CORRESPONDENT writes to us from Gwadar:—"A huge sea monster was lately discovered on the seashore at Sabar. For many days the residents of the place were in great fear and trembling in consequence of the uproar caused by the monster. After some days the noise ceased, and a great monster, lying motionless, was found. It had ponderous wings. It measured ninety feet in length from head to tail. The people have been busily engaged in converting it into oil."

A SCARCITY of water prevails on some portions of the line of the Nizam's State Railway, which has caused almost a block in the traffic. The water for the engines has to be brought in iron tanks from some distance by railway, and this, as may be imagined, is attended with great expense and delay. Mr. Howard Warden, the energetic Traffic Manager, is doing his best to remove this difficulty, and the public has every confidence in his ability to meet this emergency.

A KURRACHEE paper states that the octroi on piece-goods has at last been abolished. It was proposed to make up for the loss of the income by imposing town duties on kerosene oil, matches, articles of metal, &c., and a water rate of 2 per cent on houses. The Municipal Commissioners, however, refused to sanction any fresh town duties except on stone, aniline dyes, cheroots, and a few other articles. The proposal to charge a donkey tax at the rate of Rs. 1 8 per head was modified by the reduction of the rate to Re. 1.

WE notice that the Municipality are engaged in deepening two large holes in the bed of the Uleoor, on the Sapper side, so as to convert them into temporary wells. Some precaution should be taken to fence the holes round to guard against accidents. During the famine five of these holes were sunk in the bed of the tank, and several people, mistaking them for shallow pools, fell into them and were drowned. The late Mr. Coopoo Chetty came by his end in this way. On one occasion a cart and pair of bulls fell into one of the holes, and the bulls got drowned.

THE present scarcity of water is becoming apparent in the small quantity of vegetables now brought in the market. The high prices asked for cabbages, for instance, retards their ready sale, and the heads are becoming "small by degrees and beautifully less" in point of size, as the vendors are compelled to pull off the outer drying leaves of the cabbages remaining unsold, to make them look fresh on being brought into the market the following morning. It is supposed that if the present drought continues, few if any vegetables will be sent on to Madras, unless at fancy prices.

Selections.

GENERALLY ADMITTED FACTS WITH REGARD TO THE MANUFACTURE OF TEA.

[THE following paper has been kindly placed at our disposal for publication. It was found amongst the late Mr. Cameron's papers, and appears to have been the maxims which he had acquired during his lengthened experience of tea-making in India. They are of peculiar interest to all planters in Ceylon, as the framework on which Mr. Cameron based the teaching that had so powerful an effect for good throughout the island. It will be seen that they refer only to hand manufacture.]

1. Leaf is best withered when there is free supply of light and cool air.
2. Wet leaf is better withered in the sun or in the wind than by artificial heat.
3. Dried leaf is not necessarily withered leaf.
4. Under-withered leaf breaks in the roll.
5. Over-withered leaf gives most Pekoe tips.
6. Leaf withered in the sun gives red tea.
7. Under-withered leaf gives a green, and over-withered leaf a dark, outturn.
8. A bright coppery-outturn can only be obtained from well-withered leaf.
9. Under-withered leaf will take longer to fire than well-withered leaf.
10. Low rolling tables cause the leaf to get broken. Anything under 3 feet high is objectionable.
11. If sap comes too quickly in the roll, it shows that the leaf required more withering.
12. Too much sap makes a knobby tea from the leaf getting into lumps.
13. Small leaf cannot be successfully separated from the large before rolling.
14. Heavy rolling destroys the flavor of the small leaf, but improves the strength of the large leaf.
15. Heavy rolling discolors the Pekoe tips.
16. Coarse leaf requires all the rolling it can get.
17. Contact with iron blackens the roll.
18. The roll will color in any temperature, be it higher than, equal to, or lower than, that of the tea-house.
19. In a higher temperature than that of the tea house the color comes quickly; in a lower temperature much slower.
20. At some period of so called "fermentation" the roll gets warm. In the present state of our knowledge there is no certainty whether to check or encourage that warmth.
21. The roll gets blackened by contact with the air, and colors more evenly covered up.
22. Coloring in balls is uneven. Roll spread out over three inches to color gets mawkish.
23. The fermentation proper cannot be brought about without heat. Teas coloured in a temperature below that of the tea-house are not "fermented" in the real sense of the word. "Oxidation" or "coloring" expresses the process more correctly.

24. There is no fixed time for coloring; the proper point is determined by the eye.

25. There is no chemical or other test in use to determine the point at which to stop the coloring.

26. The color of the roll immediately before brisk firing is about the color of the outturn which will be found in the cup.

27. Pungency or rasp and a light liquor accompany a green outturn.

28. Thickness and a dull liquor attend a dark outturn.

29. Over-coloring produces a soft tea.

30. Care given to the withering ensures good color, care given to the roll ensures strength, but care will not ensure flavor.

31. In the present state of our knowledge there is no method by which flavor can be fixed.

32. Leaf opens out during the coloring and requires re-rolling.

33. Heavy re-rolling before firing softens the tea. A light pressure to excite a little moisture gives the twist and the polish required.

34. Drying in the sun gives a black and tippy tea.

35. Tea dried in the sun cups out with a metallic taste.

36. Coloring and softening go on rapidly over slow fires, and are checked by all aglow fires.

37. Quick firing gives a brisker tea than slow firing.

38. The roll spread thick on firing trays gets stewed and dull.

39. The roll has been spread too thickly when the fire cannot be seen through the contents of tray.

40. When three-quarter fired, about half an hour, trays can be safely filled up four deep, and the curing finished over slow fires.

41. Choolas can be constructed to consume one maund of charcoal, or less to one maund of tea.

42. Pucka battying develops taste or aroma.

43. Drying in the sun before packing completely desiccates the tea, but gives it a peculiar flavour.

44. Bulking is better before than after pucka battying to ensure the teas being packed hot.

45. Iron-wire, brass-wire, or bamboo trays are all good for firing, but the two former are better conductors of heat than the bamboo ones, and not liable to get out of mesh.—*Ceylon Times*.

LIGHT GRAZING IN THE BERAR FORESTS.

(*Indian Forester.*)

THE following statement shows the financial result of the scheme for light grazing introduced last rainy season into the State Reserves of the South Berar and Wun Divisions.

Sanction to the scheme was not received in time to admit of full advantage being taken of it by large cattle owners, many of whom had made other arrangements for grazing—some by sending their cattle elsewhere, others by purchasing waste lands under the Survey and Settlement Rules. The scheme has, however, been greatly appreciated, and there have been few or no difficulties in working it. It has also proved a decided success so far, and it is expected that next year the full area allotted to each head of cattle will be everywhere worked up to.

The following extract from my inspection report on the South Berar Reserves describes the appearance of the forests after they had been grazed:—

"*Light Grazing.*—I was agreeably surprised to notice the small effect that light grazing had had on the crop of grass. In most places an inexperienced person would hardly have observed that grazing had taken place at all. The grass appears to have grown almost as quickly as it was eaten, and there is still a sufficient supply left on the ground to meet all possible requirements.

"*Natural reproduction in localities lightly grazed.*—It was also a matter of satisfaction to me to notice that natural reproduction was much more plentiful in places that had been lightly grazed than in completely protected localities. This may be accounted for in great measure by cattle treading seed into the ground, and also by fewer seedlings being smothered by a rank growth of grass.

"The same result is observable in places where broad cast sowing of teak seed has been made."

In consideration of these satisfactory results, I would now beg to recommend that light grazing be extended to the whole area of the reserves, but to further protect forest interests in case of a partial failure of the rainfall, and there not being so luxuriant a crop of grass in the reserves in consequence, the area allotted to each head of cattle should be increased from 2½ acres to 3 acres.

This year in the heaviest grazed reserves, viz., Ghat Bori and Rui, where the allotment per head of cattle was 2½ and 2½ acres respectively, considerably more grazing might have been permitted without injury to the forests, and therefore, if the allotment is increased to 3 acres, there should, I think, be no fear of over-grazing in a year of scanty rainfall.

I would also recommend that buffaloes be excluded in addition to sheep, goats, and camels, as these animals are liable to browse on the young shoots of trees at the commencement of the rains, as well as to injure trees by rubbing against them when tormented by flies and other insects.

It will further be necessary, for obvious reasons, to strictly forbid grazing in localities where fires have occurred in the previous dry season.

Amongst other advantages which light grazing in reserves has brought about, I would mention the beneficial effect it has had on the neighbouring district forests, which do not show nearly so marked signs of being overgrazed as they did last year, and this improvement will be still more noticeable when additional cattle have been admitted into the reserves.

When the system of light grazing has been given full effect to, it should be possible to reduce expenditure on fire conservation very considerably. Line burning should not cost so much, and fewer fire-path watchers should be required; and in case of accidental fires occurring, the extinguishing of them should be a matter of comparative ease.

I have every reason for hoping that the introduction of light grazing into State Forests will be the means of solving the difficult problem of how best to reconcile the interests of the ryot in the matter of grazing with those of the Forest Department in the restoration of the areas committed to its charge.

By excluding sheep, goats, buffaloes, and camels—the animals most destructive to forests—and limiting the head of other cattle permitted to graze, the Forest Department prevents all possibility of serious injury occurring to its reserves, whilst it, at the same time, confers an immense boon upon surrounding villages by providing extensive grazing for the greater portion of their cattle. The grazing too is given at the time of year when it is most valued, viz., from the commencement of the rains till the end of October. After the kharif crops have been reaped at the commencement of the cold weather, cattle in Berar are, as a rule, withdrawn from their grazing ground, and fed on the stubble, &c., left in fields, supplemented by the leaves and stalks of "jowar."

When grazing for a limited number of cattle is provided in State Forests, the taking up of these areas will cease to be looked upon by the rural population as a sudden and complete reduction of their grazing grounds:—

Reserve.	Area of reserve, in acres.	Area open to grazing, in acres.	Number of cattle admitted.	Area per head of cattle, in acres.	Revenue realized.

A. T. DRYSDALE,

Conservator of Forests, Hyderabad Assigned Districts.

TIMBERS OF UPPER ASSAM.

By CHEVALIER ROBERTO PAGANINI, *late Chief Engineer, Mahām Division, Assam Railways.*

It will be easily understood that in a country where the temperature of the plains and low hills never falls below 45 degrees F., and never rises above 100 degrees F., with an average rainfall of 120 inches a year, vegetation cannot but be of the most luxuriant character and extreme variation. In fact, one of the characteristics of Upper Assam is its interminable jungles constituted in places by thick forests of colossal trees, and in others by impenetrable cane or bamboo groves.

As a rule, cane jungle will grow in swampy ground where water lodges for several months, and sometimes all the year round. Bamboo jungle will grow in low lands flooded occasionally, but where the water does not remain for any length of time. Forest jungle generally grows in dry soil, and one or other of any special tree seems to prevail according to the different altitude of the ground, or perhaps it would be better to say according to the different degree of moisture retained by the soil. The prevalence, however, of any special tree is by no means strikingly apparent. In spite of favourable ground, and the gregarious tendency of nearly all forest trees, it seems that a great variety will grow and flourish side by side in a way which would seem quite incongruous in our country. The only clear fact in these forests is the total absence of certain species of trees under peculiar circumstances. Thus, Nabor and Makahi, as will be seen hereafter, are never found in low lands, especially if subject to occasional floods, while Uriam and Hollock are never found in high, well-drained land. However, as a rule one may stand in one of these forests surrounded by trees growing as thickly as possible, and he will find it difficult to detect half-a-dozen trees of one species. This fact considerably enhances the wild beauty of the Assam jungles, but it has been up to the present time a great drawback, from a mercantile point of view, to the proper utilization of the timber. For the purpose of collecting one kind of timber is necessitates going a great distance through untrodden jungle, and after having found and cut it to the smallest size, elephants are required for the purpose of dragging it off. This process, of course, causes a large portion to be wasted, which under other circumstances would be very valuable.

The Assam Railways and Trading Company, amongst other concessions, obtained from the Government of India, have the monopoly of the timber trade for 1½ miles along each side of their line, which runs from Makum Junction to Margherita (a distance of 23 miles), and the specimens on view at the Health Exhibition came from these forests, which extend, practically, uninterrupted from end to end of the above-mentioned portion of the line.

When the Company first commenced work in opening out the country, little or nothing was known as to the real value of many of the timbers, and as the Company's works depended so much on them, they had to start at the beginning, and thus acquired an amount of information which will prove very valuable for the future of the timber trade of that country.

The following is a description of the various specimens exhibited:—

Merus ferrus.—Assamese name, Nahor; English, Ironwood; specific gravity, 1.23; co-efficient of rupture in cwt. and decimals, 27.9; loss of weight when chemically dried, 25 per cent; maximum shrinkage due to above process, 8 per cent.

There are some good patches of almost exclusively Nahor trees to be found here and there, growing on high, well-drained ground, but they are not extensive. The stem is generally straight, and the average size is from 25 feet from the foot to the first branch by 5 feet girth, maximum height found 45 feet from foot to first branch, maximum girth 12 feet 6 inches. The branches are generally thin and of no use as timber, but they produce excellent charcoal and make first-class firewood.

The timber is of a deep red colour, with very close undulating fibre, rather brittle, warps and splits when cut into planks or small scantling, heartwood not attacked by insects of any kind, and stands almost indefinitely, both exposed and under cover, without deteriorating. Before being used it should be stripped of all its sapwood, and thus prepared, forms an invaluable material for bridge piles, beams and thick scantling generally; in fact, it serves almost as a substitute for cast-iron.

Artocarpus (Aplasia).—Assamese name, Sam; English, Monkey Jack; specific gravity, 0.63; co-efficient of rupture as above, 12.3; loss of weight in chemical drying, 32 per cent; maximum shrinkage due to above process, 5 per cent.

This tree does not seem to have a preference for any particular ground; it grows in low land with as much vigour as upon the hills. It is never found in patches, but is liberally scattered all through the jungles. The stem is seldom very straight and branches off soon, sometimes at a few feet from the ground, but the branches often produce good timber. It is of a bright yellow colour when cut, and deepens into a brown walnut colour in the course of time. The fibre grows pretty straight, not very close, breaks short, and receives easily a clean polish. It warps and splits very little. It stands well either exposed or under shelter, and insects will not attack it. It is a very useful timber for any purpose where great strength is not required, being specially adapted for household furniture, as it is equal or superior to teak for this purpose.

Bischofia javanica.—Assam name, Uriam; English, none; specific gravity, 1.04; co-efficient of rupture as above, 15.2; loss of weight in chemical drying, 24 per cent; maximum shrinkage due to above process, 10 per cent.

It grows abundantly, though never gregariously, along the banks of the rivers in the low plains, and preferably where occasional floods cover the ground. It sometimes grows straight, but not generally so. Thick branches soon divide the stem, and yield useful timber. The girth of the stem varies very much, and the timber obtained from one of 4 feet girth seems to be as good as that obtained from a 12 feet girth (which size is not uncommon). The timber is of a dark cold red colour, the fibre straight and close, and hardly recognisable; it warps and cracks under shelter, and if the place is very dry becomes very brittle. White ants will attack it. On the other hand, it is almost imperishable in wet ground or under water. This circumstance makes it particularly suited for pile foundations and railway sleepers. And for this latter purpose especially, we believe, considering the present prohibitory prices of other wooden sleepers in India, it will soon become very useful.

Terminalia Myriophyllum.—Assamese name, Hullock; English, unknown; specific gravity, 1.06; co-efficient of rupture, as above, 13.4; loss of weight in chemical drying, 35 per cent; maximum shrinkage due to the above process, 2 per cent.

This tree grows under the same circumstances as the Uriam, and almost invariably where Uriam is to be found Hullock is also found; it is not so abundant as the former, but grows to a much larger size, and shows a gregarious tendency here and there. Although branches are often to be seen starting a few feet from above the ground, it possesses generally a long stem growing to a considerable height, and the branches yield good timber. It is frequently recognised by its towering above the surrounding trees. The stem also grows to a great thickness, 10 feet to 12 feet girth being the ordinary size, but one on being measured was found to be 21 feet girth. The timber of young trees is almost valueless, as not only is it greedily attacked by the carpenter-beetle and other insects, but soon deteriorates when exposed to the climate. On the contrary, the timber of the maturer trees is excellent for many purposes, straight grained, pretty hard, of a brown colour, does not warp or split to any considerable extent, even when not seasoned, stands well in and out of doors without deteriorating. Its only enemy is a kind of small borer, which is easily got rid of by painting it with crude petroleum or coal tar. It is peculiarly adapted for cheap furniture, windows, doors, railway carriages, and generally for any work where accurate fitting is the main object.

Dipterocarpus Pisonia.—Assamese name, Holong; English, none. No experiments have been made on this timber. It grows in high well-drained land, is not gregarious, but is pretty thickly scattered about. Its stem is very straight and attains a very large

size, averaging 8 feet girth and 80 feet to 50 feet from foot to the first branch. Instances of 18 feet girth by 80 feet to the first branch are not unfrequent.

The timber is of a reddish-brown colour, close and pretty straight grained; it does not warp or split much, but quickly deteriorates unless kept in a dry and ventilated place; it is attacked by nearly all timber insects. Thus, notwithstanding its large size, it is of little or no use, except for temporary purposes and for packing boxes; it must, however, be borne in mind that in Assam this latter use forms a very important business, as not less than 400,000 boxes for packing tea are used yearly, the making of each one requiring about 1.50 cubic feet of rough timber. A large quantity of such boxes are now imported from Calcutta, and the balance is made by hand saw, and a few sawmills, which are busily engaged exclusively in that trade all the year round.

Shorea Asamica.—Assamese name, Makahi; English, none; specific gravity, 0.82; co-efficient of rupture in cwt. and decimals, 13.2; loss of weight in chemical drying, 36 per cent; maximum shrinkage due to the above process, 5 per cent.

This tree deserves, for many reasons, more attention than any other. It is, for one thing, quite a new tree, so to speak. It was but a few years ago that Mr. G. Mann, the Conservator of Forests in Assam, took special notice of it, and studied and classified it with the devotion and care peculiar to all true naturalists.

To the best of my knowledge, it grows exclusively along the hills on the south bank of the Dehing river, forming a belt which thins out and eventually disappears as it approaches the Patkoi range to the south, and the Jaiपुर (Assam) district to the west. How far it extends eastward I cannot say. Not one Makahi tree is to be found north of the Dehing river. It grows to various heights, and always in well-drained ground. Its gregarious tendency forms an exception to all other Assam trees: in some places, the forest is almost exclusively constituted by Makahi trees and in all cases it grows so thick that were all the other trees to disappear, there would still remain a good Makahi forest. Its stem grows perfectly straight to a height averaging 70 feet to the first branch, and a girth of 8 feet. It is not unfrequent to find some of 90 feet or even 100 feet to the first branch, and 12 to 14 feet girth. In the construction of some bridges I required fifty trees that should not measure less than 8 feet girth at 60 feet above the ground, and I found them all within a radius of a mile from Margherita. The timber is almost white when newly cut, but soon turns to a dark yellow colour and brown if exposed to the open air. Its grain is very straight and not very close, and warps and splits when quickly dried but not otherwise. It soon rots away in the ground or when subject to constant and abundant moisture, but stands very well under cover or in the open air as long as water cannot lodge in contact with it. White-ant and borers will attack it.

Notwithstanding the lasting qualities of this timber not being very superior, we consider that at no distant date Makahi is destined to represent an important item in the timber trade of India. We may incidentally mention that its liability to rot and to be eaten by insects can be disposed of by pickling, and that this pickling has proved to be very effective when done with crude petroleum, of which there are abundant springs belonging to the Assam railways, right in the centre of these forests. But independently of that a cheap timber for general purposes, to be used as common deal is used in England, has been entirely wanted up to the present in Assam and Bengal. Bamboo is often substituted, but as often as not this does not answer, and then the expensive teak or sal is used. Makahi does not present the same difficulty as other Assam timber in felling and collecting; it is easily worked, leaves little waste on the ground, and there is such a quantity as will supply the market for many years to come. Up to the present it has been practically unknown and inaccessible. This latter difficulty has been done away with by the opening of the railway from Dibrughur to the Makum coal-fields. The former will disappear as fast as the advantages of this timber are recognised.

We will finally remark that, besides the trees above mentioned, there are at least a dozen more species equally good, though not so abundant. The great drawback of their growing so mixed is, in the case of the Assam railways, removed to a great extent by the peculiar feature of its timber concession, owing to which the farthest tree has never to be dragged by elephants more than 1½ miles to reach the railway.—*Timber Trades Journal*.

LIGHT MANURES.

By DR. A. P. AITKEN,

Chemist to the Highland and Agricultural Society.

When a farmer has discovered by experiment what are the wants of his soil as regards the three chief ingredients of manure—nitrogen, phosphoric acid, and potash—for the growing of certain crops, the chief difficulty in the selection of light manures is overcome. He has next to consider in what form he ought to apply the required substances, and that is by no means an easy matter, for the assiduity and enterprise of manure manufacturers have provided for him a very great variety of materials whose very names are perplexing, and whose compositions and characteristics are frequently but little understood. Every year sees the advent of some new kinds of manure, and the market is constantly changing. Old manures are being presented under new names, and sometimes new manures under old ones, so that much care and discrimination are

needed in choosing the form of manure which shall contain the ingredients suited to the needs of the buyer. In the subjoined table are given the percentage of the valuable constituents of the chief kinds of manures :—

COMPOSITION OF LIGHT MANURES.

	Soluble Phosphate.	Insoluble Phosphate.	Ammonia.	Potash.
	per cent	per cent	per cent	per cent
PHOSPHATIC MANURES—				
Mejillones Guano	72
Maiden Guano	74
Mona Island Guano	50
Estremadura Guano	40—80
Canadian Apatite	82
Curacao Phosphate	75
Aruba do.	80
Ardennes and Belgian Phosphates	63
Carolina and Charleston Phosphates	50—80
Coprolites	40—80
Bone Ash	75
Bone Char	00
Superphosphate ...	15—40
NITROGENOUS MANURES—				
Sulphate of Ammonia	25	...
Nitrate of Soda	19	...
Dried Blood	15	...
Horn Dust	13	...
Shoddy	5—10	...
Leather	5—9	...
POTASH MANURES—				
Muriate	50
Sulphate	27
Kainit	12
CHIEFLY PHOSPHATIC—				
Bones, Bone Meal, &c.	50	4½	...
Steamed Bone Flour	60	1½	...
Vitrified Bones (av.) ...	12	20	3½	...
Genulose Dissolved Bones ...	20	12	2½	...
Peruvian Guano (guanine)...	77	40	5	...
CHIEFLY NITROGENOUS—

Peruvian Guano (old residues) ...	10	20	10	3
Fish Guano	30	10	...
Frey Bentos Guano	16—30	12—6	...
Flesh Meal	0	12	...
Rape and Cotton Cake Dust	1½	5	1½

Regarding phosphatic manures, it may be said that their use in the undissolved state has only recently attained what might be called important dimensions. The vast bulk of these substances goes to supply the raw material for the manufacture of superphosphate, so that the composition and character of the various phosphates enumerated are of interest rather to manufacturers than to farmers. Experiments which have been carried out in Scotland during recent years—in Aberdeenshire and also at the Highland and Agricultural Society's stations—show that undissolved phosphates, if only ground fine enough, are quite serviceable as manure, and though they cannot be said to have been found to be either so successful or so universally applicable a form of phosphatic manure as superphosphate, yet there is no doubt that on certain soils and in certain circumstances they are to be preferred to that manure. The soils which, in my experience, have given the best results with ground phosphates, are moory soils rich in organic matter. On such soils, ground phosphate, when applied for the turnip crop, have usually done better than superphosphate, but instances are not wanting in which they have shown their superiority also on clay land. They are a slow acting manure, and are therefore applicable only to crops like the turnip, which have a long period of growth. The experiments carried out by Mr. Jamieson in Aberdeenshire—on a small scale certainly, but yet very carefully done—showed that, upon the whole, ground phosphates were to be preferred to superphosphate, and although the results of experiments in other parts of the country do not quite corroborate the Aberdeenshire experiments, there is enough of evidence to show that ground phosphate may be a very good manure, and more economical in some cases than superphosphate. The experiments made to determine the relative value of these two forms of manure have usually been conducted on the basis of making the amount of phosphates equal in each case, so that the crop manured with superphosphate received its sulphuric acid in addition, and had, therefore, more money expended on it. Had the experiments been on the basis of equal money value, it is probable that the money spent in

dissolving the phosphate might in many cases have been more economically applied in increasing its amount. That is a question which each farmer must decide for himself. There are two facts that are clearly brought out by the Scottish experiments. First, that there are only some kinds of phosphate that are of any use when applied in the undissolved state; and second, that even the best of them fall unless they are ground down to the state of very fine flour—what is called an impalpable powder—so that no roughness or grittiness can be felt when rubbed between the finger and thumb. It must be confessed that it is not easy to determine whether a sample of phosphate is all of one kind, and that a favourable one; and the sense of touch is not one on which a farmer can rely, for the delicacy of that sense varies greatly among individuals, and even with the same individual according to the use he has been recently making of his hands. In order to prevent disappointment or loss in the use of ground phosphate, a guarantee of purity would be necessary, and a standard of fineness adopted, such as that proposed by the Chemical Committee of the Highland Society two years ago, which was a sieve of wire cloth, having 80 wires in the linear inch. So far as my experience goes, the best mineral phosphate for applying in the finely-ground state is Charleston phosphate, and the worst is Canadian apatite; but if the use of ground phosphate is to become more general, it would be desirable to have a set of experiments made with the various mineral phosphates, of equal fineness, to determine their relative suitability for immediate application.

It is one of the advantages of superphosphate that it is a matter of indifference what is the kind of phosphate that has been used in making it, so long as it has been thoroughly dissolved. All that is required is that it be in a fine dry state, and not in the least lumpy—as superphosphates very frequently are—for even little lumps the size of a pea are a disadvantage in a superphosphate, and greatly impair its usefulness. When superphosphates are too new, or when they contain more than about 28 per cent of soluble phosphate, they are liable to contain many little lumps, and that is why the medium superphosphate in the Highland Society's stations has produced the best results.

When a superphosphate is put on the land, its soluble phosphate becomes insoluble very soon, almost immediately, if the land is rich in lime—and in so far as solubility is concerned, the phosphate so produced may possess no advantage over the insoluble mineral phosphate, but there is one great advantage gained, and that is, the exceedingly fine state of division in which the phosphate is precipitated in the soil. The more finely a phosphate is divided, the greater is the extent of its surface which is exposed to the solvent action of the roots of the crop, and it is to the enormously increased surface so exposed that the rapid effect of superphosphate is to be attributed. If the land is rich in lime the soluble phosphate will be precipitated as phosphate of lime, but if it is poor in lime, the soluble phosphate will enter into combination with oxide of iron and alumina in great measure, and form insoluble phosphates with these substances.

The kind of precipitate formed in different soils will, therefore, vary very much according to the relative abundance of these basic substances, and experience shows that in some soils the precipitate formed is of a much more insoluble kind than in others. We are, therefore, led to the conclusion, that when land is poor in lime, there is an opportunity given to the superphosphate to be converted into a more insoluble phosphate than the original mineral from which it was manufactured, and in such a case it is easy to see that it would have been better if the finely ground original mineral phosphate had been applied in the undissolved state. Another inference to be drawn from this fact is, that the application of lime to a soil which is poor in it will have the effect of preventing this very insoluble iron and alumina compound from forming, and will cause the superphosphate to be converted into the insoluble phosphate of lime, which, though it is insoluble in water, is nevertheless easily soluble in acid, and what is more important, it is easily dissolved by the solvent action of the roots of plants. I have no doubt it is within the experience of many farmers that superphosphate did better on land after it had been limed than it did before the liming, and I think it highly probable that in those cases where it is found that mineral phosphate is more efficacious than superphosphate, the tables will be turned if a light liming is given to the land.

As a rule, phosphate applied in the soluble form has marked advantages over insoluble phosphate. It is far more reliable; it makes a more uniform crop; it acts very quickly, and may therefore be applied with advantage to short-lived crops; it usually makes a more abundant crop, and at Pumphreyston station it has always made an earlier crop. But this is not a subject on which to dogmatise, for soils vary infinitely, and therefore my advice to farmers is—prove it for yourselves.—*North British Agriculturist.*

INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA:—SATURDAY, MAY 30, 1885.

[No. 22.]

Crop and Weather Report.

[FOR THE WEEK ENDING MAY 20, 1885]

GENERAL REMARKS.—Rain has again fallen throughout the Madras Presidency, but, except in the Ganjam and Kistna districts, the falls were too light to be of much benefit to the crops, which still want rain in some districts. No rain has fallen in Mysore, where prospects remain unaltered. Want of pasturage for cattle continues to be felt. In Bombay slight rain fell in 13 districts; rain has fallen also in the Punjab generally, and in parts of the North-Western Provinces and Oudh and the Central Provinces. In Bengal proper and Assam good rain has fallen generally. Rain was also general throughout the Central India and Rajputana States, and prospects continue good.

Agricultural prospects remain unaltered in Madras. The *rabi* harvest has been completed in the Central Provinces, and is approaching completion in Bombay, the Nizam's Territories, the North-Western Provinces and Oudh, and the Punjab. *Kharif* operations are in general progress throughout these Provinces and the Berar. The recent rain has much improved the prospects of the standing crops in Bengal, and has facilitated agricultural operations. Early paddy and jute are being sown in many districts, and harvesting of *boro* paddy continues. Ploughing and sowing continue in Assam; and tea is reported to be doing well in Cachar.

Cholera, small-pox, and fever are reported to a greater or less extent from most Provinces.

Prices are fluctuating in the Punjab; elsewhere they are generally steady.

Madras.—General prospects fair, except in parts of Bellary and Anantapur.

Bombay.—Slight rain in parts of 13 districts. *Rabi* harvest completed in all districts, except Shikarpur; preparation for *kharif* crops in progress in 9 districts; scarcity of fodder and drinking water continue in several parts of Dharwar and Belgaum. Cholera and small-pox in parts of 13, fever in parts of 12, and cattle-disease in parts of 6 districts.

Bengal.—Rain fell almost everywhere during the first part of the week and has facilitated agricultural operations and improved prospects of standing crops; early paddy and jute are being sown in many districts; harvesting of *boro* paddy still continues; mango is a poor crop. Prices of food-grains generally steady. Cholera and small-pox prevalent in many districts.

N.-W. Provinces and Oudh.—Rain has fallen in most districts. Harvesting operations very nearly completed, outturn good. Markets well supplied and prices steady. Cases of cholera reported from a few districts.

Punjab.—Rain in nearly every district. Cholera in the Umballa and Mooltan districts abating; virulent fever in a few villages of the Peshawar district; health otherwise generally good. *Rabi* being harvested, outturn in the Umballa, Sialkot, Lahore, and Shahpur districts partly damaged by rain; *kharif* operations in progress. Prices fluctuating.

Central Provinces.—Weather hot, with occasional storms. *Kharif* preparations progressing. Cholera continues in Hoshungabad, Nijmar, and Raipur. Prices steady.

British Burma.—Cholera, which has abated in Pegu, is slightly prevalent in Akyab, Kyaukphyoo, Thongwa, and Amherst; some cases of small-pox in Kyaukphyoo, and Tharrawaddy; otherwise public health generally good. Cattle-disease prevalent in 3 districts. Rain has fallen in most districts. Weather cooler.

Assam.—Weather hot. Sowing of *aus* almost over; prospects good; ploughing operations for *am* crops in progress. A few sporadic cases of cholera reported.

Mysore and Coorg.—Crops in good condition. Prices generally stationary. Prospects of season and public health good.

Berar and Hyderabad.—*Rabi* crops continue to be reaped. General health fair, except in Shahabad and Marhal taluks, where cholera prevails. Prices—wheat 15, coarse rice 12½, white *juari* 23½, yellow *juari* 23½, and *tur* 17 *seers* per current *moos* rupee.

Central India States.—Weather hot. Health good. Prices steady.

Rajputana.—Weather cloudy and reasonable, but cool for the time of the year; high winds prevail. Health good.

Nepal.—Weather stormy and cool. Prospects moderate. Health in the valley of Katmandu good.

Letters to the Editor.

SEEDLINGS FROM FRUITS.

TO THE EDITOR,

SIR,—I hope you will allow me a little space for the following remarks:—It is a general belief among the cultivators and gardeners of this and other places that mangoes grown from such seeds, the fruits of which have been eaten, invariably produce inferior and sour fruits. The same is said to be the case with pomegranate and other fruit trees. The reason assigned by the natives is that the seed is affected by the saliva of the mouth and is poisoned by it. The science of botany informs us that the seed coat bursts open on germination of the seed; and the young plant derives its nourishment from the true seed and not from the coating. Be that as it may, the natives have a strong belief in the saliva-poisoning theory. I am, therefore, unable to find the true scientific explanation for this. Would you, therefore, or any of your readers, favor me, through your columns or otherwise, with a true and reliable explanation of the above mentioned belief?

R. D. JANEY,

Agricultural Department, Bhavnagar State.
Bhavnagar, 16th May 1885.

NOTE.—We cannot explain the "saliva" theory, but we would refer our correspondent to the *Indian Agriculturist* of the 2nd instant for an explanation of the deterioration of fruit plants raised from seed.—ED., I. A.

DESTRUCTION OF WEEDS, &c.

TO THE EDITOR,

SIR,—Will you, or your correspondent, Baboo Hem Chunder Dutt, kindly enlighten me and a number of agriculturists with the method of destroying rank grass, weeds, &c., and of fertilizing soil so that it may become sharp, porous and friable; and thereby oblige—

ANOTHER FLORIST.

Calcutta, 19th May 1885.

DESTRUCTION OF RANK GRASS, WEEDS, &c.

TO THE EDITOR,

SIR,—With reference to the query of your correspondent "Another Florist," I beg to suggest to him the following method, for the destruction of rank grass, weeds, &c., which will also make the soil sharp, porous and friable:—

Spread thinly a layer of gas lime over the ground, as a "top dressing." If gas lime fresh from the purifiers be applied to soil, the salts which it contains will destroy vegetation. It is, therefore, necessary to expose it to the atmosphere in order to transform the injurious sulphur compounds into fertilizing agents. The sulphur and ammonia which render fresh gas lime fertilizing agents, and become destructive to vegetation, are the ingredients so valuable in decomposing compost heaps; it therefore follows that the fresher the gas lime can be applied to compost heaps, the sooner the results required will be obtained, as the salts which go off with exposure to the air, have a powerful effect in decomposing the vegetable substances in compost heaps.

Such composts when applied as manure, after three or four months, contain sufficient salts and tarry essences to make the substance ungenial to insect life, so that by the application of such manures, a double object is obtained—*1st*, the fertilization of the soil, thereby rendering it more sharp, porous, and friable, and *2nd*, the destruction of insect life.

It must be remembered that the apparent crystallization of gas lime is due to its exposure to the atmosphere.

HEM CHUNDRA DUTTA.

Raghoo Nath Chatterjee's street,
Malabar's Cottage, the 21st May, 1885.

CEARA RUBBER (MANIHOT GLAZIORI) IN THE KULSI PLANTATION, KAMRUP, ASSAM.

TO THE EDITOR.

SIR,—A small quantity of Ceara Rubber seed was received in June 1879, and sown on the 25th of that month on a seed bed situated on the spur of a hill facing the east. The soil of this spur is very deep, being composed of a brown or reddish loam mixed with a portion of clay. The consistency of the soil is neither very stiff nor very loose, but moderate. In appearance it is somewhat like the laterite soil of Eng forest in Burmah, or of the ferruginous soil of the Sivalik hills. The hill from which the above spur projects is situated on the right bank of the Kulsi river, which, issuing from the Khassia hills, joins the Brahmaputra at an equal distance between Gauhati and Goalpara. Teak plantations of some 8 or 9 years' standing cover the hill alluded to above. On the extreme end of this spur, which terminates rather abruptly in the Kulsi river, is erected a beautiful bungalow for the accommodation of the Forest officer. This bungalow faces the south, and commands an extensive view, covering some miles, of the Kulsi valley. The site selected for the nursery of the Ceara Rubber is protected on the two sides, north and west, by the range of hills which run almost parallel to the Kulsi river. Thus the violent north-westerly winds, which blow with much force for many months of the year, have less effect on the nursery bed than would have been the case had it been situated on some other open place. The climate of this place may be said to be semi-tropical. The rain commences from the middle or end of April, and lasts till the beginning of November. The average rain fall is 78 inches and the average temperature is about 70 Fahr.

The seed was sent for an experiment to ascertain whether this plant, whose native home is at Ceara in Brazil, would grow as well in Assam, the climate of which place is said to resemble that of the Ceara district. As stated elsewhere, the seed was sown on the 25th of June, but nothing came out till the end of September, when only two or three seeds germinated. The seed is very hard, harder than a plumstone. It is about the size of a small bean. Its vitality is wonderful. The seed sown in June 1879 was taken out from the nursery bed in March 1881 without being injured or decayed; and one of them left in the bed germinated in July 1882, after being for over three years in the ground. Some of the seeds thus taken were filed in order to hasten their germination, if possible, while the rest were soaked in a weak solution of sulphuric acid and water for a day. They were sown again after undergoing the above processes separately in two beds. Of those which were filed only two germinated within a fortnight, but none of those steeped in sulphuric acid and water. This simple fact decided Mr. Mein, the divisional Forest officer, to adopt the method of filing the Ceara Rubber seed before sowing it, and it has acted admirably well in respect of easy germination. Before experience was gained on the subject, the seeds were filed sometimes on the top, at right angles to its longitudinal axis, thus increasing the aperture of the hilum or micropyle, and sometimes on the two sides of the hilum securing the hard testa so that it may easily burst at the time of germination. The second system was very successful while the first system failed altogether. Thus by the second system all the seeds germinated within from 14 to 44 days.

The young seedling with the two cotyledonary leaves looks like the castor-oil plant, but soon after, when more leaves come out, its appearance changes and the plant is sometimes mistaken for a Papia seedling, for its juice resembles that of the Papia plant. When the seedlings are 9 inches or 1 foot in height they are transplanted in suitable localities, and are well fenced, lest the deer should take a fancy to them. As regards locality, perfect drainage of the soil and subsoil is essentially necessary for the cultivation of this plant. It also prefers open high ground and hill-sides to shady or low-lying grounds. The growth of this plant is wonderfully rapid. The two seedlings which came up in September 1879 were found, when measured on the 16th June 1880, to be 6ft. and 3ft. in height respectively, and in May of the following year 21ft. 8in. and 14ft., so that one of them has grown over 1ft. per month. Another plant on measurement was found to be 19ft. in height. It is a very soft-wooded tree, and requires strong wooden posts for support. The tree will probably coppice well. One small plant was broken to the ground by a violent storm, and the stool, after a few days, had been noticed to throw out fine and vigorous shoots. It can be easily propagated by cuttings, since some of the branches were cut and planted out with a view to propagate it, and they were seen to sprout. In the Kulsi plantation, there are now probably 150 plants from 4 to 40ft. in height. Their births vary from 2 to 20. Here the trees begin to lose their leaves in January, and remain leafless for more than a month. At that time they very much resemble in appearance a birch tree, and the surface of the bark comes off in the same way in their peelings. The seed-bearing trees are the last to put forth leaves, and this they do when all the seeds have fallen to the ground, the two biggest trees seeded profusely during the past two years. They commence to flower in the beginning of December and the seed ripens by the beginning of March. The bunches of ripe fruit remain on the tree while it is leafless. The pod when ripe bursts, and goes to pieces, so that the seeds are scattered on the ground at some distance from the parent tree.

JOHNSWAN SEN.

Dhubri, 25th May 1885.

Editorial Notes.

We print elsewhere an article entitled *The End Stage of the Future*, extracted from a home contemporary. It is a review of Mr. G. Fry's book bearing that name. We have read this article with much interest, and reproduce it in extenso.

We find that the net amount of Indian sea and customs revenue, exclusive of salt revenue, for the first and last of the current financial year, was Rs. 12,77,000, as compared with Rs. 12,42,000, during the corresponding month of the last year.

Those interested in the subject of the supply of Indian grass and other fibres for paper-making, will be glad to learn that there is a practically unlimited quantity of the *babui* grass to be obtained along the Nepal frontier, within our territory, and that considerable quantities are already being sent by the Tirhoot State Railway to Calcutta.

We cannot say how far it is true, but it is reported that the whole of the mining rights in the Nizam's Dominions have been leased to an English company, supposed to be Messrs. Watson, Stewart, and Co. This may be a move in the right direction; but as we have received no particulars, we are not in a position to express an opinion on the subject.

The Indian Association sent the following telegram, we understand, to the Lieutenant-Governor at Darjeeling the other day:—

A great scarcity of water prevails at Nulhatti, Nowada, and other parts of Beerbhoom. The re-excavation and digging of tanks are essential, and require prompt attention, and pecuniary advances are necessary for the purpose.

The Association is quite right in keeping the attention of the Government constantly drawn to the subject.

We are glad to learn that the Madras Government have hit upon another, and more practical, means of finding employment for poor Europeans or Eurasians. The intention is that three European or Eurasian pupils are to be attached to each of the four Native Cavalry Regiments in Madras, with the object of being trained as veterinarians. After they have acquired a sufficient knowledge of the subject, and have qualified as farriers, they will either be drafted into that branch of the military service, or the Government may permit them to be employed as veterinary practitioners in the district, or in connection with public or private companies. The suggestion for this experiment, we hear, emanated from Sir Frederick Roberts, and we hope that the required number of young men of the proper stamp will be forthcoming for this service. The experiment ought, we think, to prove successful, and may, with advantage, be tried in the other presidencies.

The table attached to the report of the Board of Revenue on the Road and Public Works Cess operations for the year 1883, shows the number of estates and tenures assessed, and the number of recorded shareholders for each district. The figures include only estates and tenures assessed with road cess, and it follows, therefore, that all revenue-free estates situated within the boundaries of municipalities, all revenue-free estates of which the value is less than five rupees, and all tenures of less than a hundred rupees annual value, are excluded from the statement. Such as it is, however, the table shows that the total number of estates in the province is 2,62,254 and the number of recorded proprietors, 12,11,519, giving on an average 4.6 shareholders to every estate. The figures also show a total number of 11,91,218 tenures, or an average throughout the whole of Bengal of 4.5 tenures to each estate.

SERICULTURE in India has made very rapid progress in recent years; but however much we may know of the habits and food of the silk-worm, any information that will add to our knowledge of the subject must be received with satisfaction by all.

interested in the industry. We thus learn that Mr. Hosie, who travelled through the Province of Szechuen in June and July last year, discovered a new tree, which is extensively cultivated in the western parts of the province as a source of food for silkworms. He describes it as follows:—It stands from 10 to 15 feet in height, and resembles an overgrown tea tree. The leaves, which spring alternate from the branches, are of a dark green colour, smooth, ovate, acuminate, and not serrated. It is very extensively grown, and its leaves are used to feed the silkworms in their infancy. The local name is the *tea* (also in the north.) *Yeh* tree. It is apparently a species of thorn. The peasantry insist, that unless the young silkworms are fed with the chopped leaves of this tree, the output of silk will be less and of an inferior quality.

If the properties ascribed to it are to be accepted as correct, the Government of India in the Agricultural Department would do well to take some measures to procure specimens of the tree for experiment in India.

**

We have before us the results of the experiments made last year at the Cawnpore Model Farm in the preparation of ensilage. The experiments were tried on an extensive scale, there being ten earthen pits and three masonry pits filled. The crops made use of were *juar*, sorghum, guinea grass, and common grass, the first three being grown on the farm, and the latter purchased from grass-cutters at the rate of one anna per 82 lbs. The grasses were cut just as they were coming into flower: the sorghum and part of the *juar* were cut when the cobs were fully formed, and ripe enough to allow of their being cut and stored; the stalks were quite green, although they had lost a good deal of their moisture. The *juar*, sorghum, and a portion of the guinea-grass were cut into chaff before packing, whilst the common grass was put in as it was brought from the fields. The earthen pits were nearly all circular in form, a little broader at the top than at the bottom, so as to give a slight slope to the walls. Seven of the earthen pits were covered with *chuppers* to protect them against the rain, and over three others a sloping mound of earth, three feet high, was made. In the case of the larger pits, an opening was cut at one of the sides to allow of the entrance of a bullock to tread down the stuff. The silos were filled in layers, each layer after it had been trodden down being sprinkled over with a little salt, and covered over with *bhusa* to the depth of about two inches. The intermediate layers were weighted with pieces of bricks, and the final layer, after being pressed down, was covered with earth to the depth of two or three feet. The cost of making and filling the silos was trifling compared with the outturn. Thus, for example, a circular silo, ten feet in diameter, and only six feet in depth, cost altogether for ensilaging 171 maunds of *juar*, Rs. 9-15-6, divided as follows:—Cost of digging, Rs. 0-12-0; of *chupper* for covering, Rs. 2-8-0; of cutting into chaff, Rs. 5-3-6; of filling, treading down, and weighting, Rs. 1-8. Another experiment in ensilaging 725 maunds of common grass in an elliptical silo, 18 feet in diameter and 10 feet in depth, cost Rs. 34-14-9, and, considering the amount of stuff that is produced by it, it appears to be the cheapest method of obtaining fodder.

It would, however, have been interesting to know the quality of the ensilage produced; but as nothing is said upon this point in the Report of the Farm for 1864, we are not in a position to offer any remarks on the subject. We observe that a change has been made in the designation of this Farm. It is now called the "Cawnpore Agricultural Station."

**

We called attention the other day in the pages of the *Statesman* to the terrible distress that exists in the Moorshedabad district, and we have now before us a letter from Nulhati in which the writer says:—

I beg humbly to call your attention to the great distress that is prevailing in the Beerbhoom district. The scarcity is gradually assuming a fearful shape, and relief measures should be at once organised on a more extensive scale. Cholera is moreover decimating the population, and the want of water is being severely felt, while hunger is compelling the poor to take the most unnatural kinds of food; others wander away from their homes, leaving their helpless wives and children to their destiny. Though several relief centres are supporting nearly 6,000 persons, a very large number remain to be relieved. For the able-bodied, relief works

should be opened by the Government, or their future will be most gloomy. The ryots are so impoverished that if the Government does not grant them small loans on favorable terms, there is no hope of the land being tilled at all this year. Let me beg you to bring your influence to bear upon the matter.

Is it not most melancholy that we can sanction an expenditure of crores of rupees, in futile preparations for war in almost any direction, and upon almost any pretext, for the destruction of human life, while the doors of the Treasury are closed without remorse, upon people dying of hunger within fifty miles of us? It is the literal fact, that we hesitate far less over an outlay of a crore of rupees upon military fire-works, than over a grant of Rs. 10,000 to save our starving poor from the last extremity of famine. The Government finds not the slightest difficulty in providing ten, fifteen, or twenty crores of rupees at any moment for war, but cannot find ten, fifteen, or twenty thousand to save our own villagers alive. We boast of our civilization and enlightenment, while our conduct is that of simple barbarians. An expenditure of a few lakhs of rupees would save all the suffering the people are enduring, and the custodians of the public purse assure you that they positively cannot afford it. How is it that the money is always there for war?

Since the above lines were in type, we have received the following telegram from Sainthia:

The scarcity of water is seriously felt at Nowada, Nulhati, and elsewhere. Cholera moreover is raging at Nulhati, and no time should be lost in helping the people with advances (*lucavai*) to dig, or excavate tanks. Delay will cause great suffering.

We have no desire to reproach the local Government, but we are strongly persuaded that its action is not adequate to the need of the people.

**

The Commissioner of the Presidency division sends us the following telegram, received by him from the Collector of Moorshedabad, in reply to the statement of the special correspondent of the *Bangabasi*, reproduced in a recent issue of the *Statesman*, that 31 deaths from starvation had occurred in thanna Khurgram, of that district:—

No deaths from starvation at Khurgram, nor immediate likelihood of any. Rest of thanna better off.

The Government must not be surprised if we receive the usual official assurances as to the condition of the people, with distrust. It seems ungracious to do so, but we have so painful a memory of what such assurances have been worth in the past, that we find it impossible to accept them without reserve. We cannot contradict the above telegram, but the special correspondent, who forwarded it to us, should at once say upon what testimony his statement was made. For the rest, we do not think it hypercritical to remark upon the strange expression in the telegram, that there is no 'immediate likelihood' of any of the people dying of starvation. The words certainly seem to indicate that the distress is extreme, and when we hear of distress of this order being relieved by a dole of 'two pice' a day to the people who are starving, we are not satisfied, nor should the public we think be so. To this hour, in no part of India does the Government ever assume the right attitude, when calamity of this kind comes upon the people. We are not speaking lightly when we say so. Where the people are without work, and food is at very high if not quite famine prices, it is an absolute mockery of their condition to make a dole of half-an-anna a day to each as relief. It means starving them to death slowly, and is an attempt to make a compromise with claims that admit of none. As there is no poor law in the country, but a professed provision for famine, the Government is bound to adopt adequate measures of relief for the people, and we feel bound to say it does nothing of the kind. It gives the scantiest possible assistance, where it is bound to give full and adequate relief, and boldly and systematically devolves upon private charity, a responsibility that such charity is quite unable to discharge. At all these periods, the Government makes it a rule of leaving the assistance of the destitute high caste and zenana classes, to the efforts of private philanthropy. All that it has a right to expect from that philanthropy, is done, when private associations have been formed for ministering to the misery of the classes who retire into their houses to

die, because they cannot go like coolies to the relief works or soup kitchens. We ask Sir Rivers Thomson himself what prevents his placing means at the disposal of the private organizations that have existed for months past, for the relief of distress that retires from the public gaze. He has ample guarantee in the character of these associations, for trusting them and *should* trust them, and give them all the encouragement in his power, to discharge their humane but painful and self-imposed duties, with success. It is not the Government of Bengal only, that fails to grasp the right idea as to how these calamities require to be met. There is not a Government or Administration in the country, that shows a just understanding of its responsibilities in these crises, and the proof of it is the instinctive way in which they all look to the public, to share a responsibility that is entirely their own. At this moment, there are, we believe, two or three private societies formed for the relief of classes who will die, if they are not sought out and relieved in the privacy of their homes; and what could be more legitimate than for the Government, after making proper enquiries, to constitute these private societies its almoners? Can we really do nothing for the people, except through the workhouse, or the contractor with his spade and shovel? We believe far more might be done also, by *woodvi* advances at these seasons. It should be sufficient for the district officer to report, that there was actual suffering amongst the people, for the purse-strings to be freely loosened. What if ten, twenty, or thirty thousand rupees are spent without much return? Will it ruin us? What is really necessary is to get rid, once for all, of the 'grinding' idea that pervades all our relief steps.

.

THE subject of the assessment upon trees has been engaging the attention of the Madras Government. Mr. Pennington, the acting Collector of Tanjore, submitted to the Board of Revenue a set of rules which he thought would meet the case, and which the Board proposed to apply. The Government, however, in passing orders, observed that the rule which Mr. Pennington and the Board proposed to apply in the Tanjore district was entirely opposed to the custom of the district, which was recognized and ordered to be maintained in previous orders. The papers under consideration showed that the property of the mirasidars in taxed fruit trees growing on assessed land, in backyards, in village-sites, on the margins of fields, [called ryot's or individual (Assami) poramboke in Tanjore] and in avenues planted by them was fully recognized. The same was the case in regard to trees planted by mirasidars on channels and river banks. As regards isolated fruit trees, on other porambokes and on unassessed land, the principle that the property of the original planters, or their heirs, if known, should be recognized, ought to be followed, though there were no express orders on the point. The presumption in Tanjore was decidedly in favour of the mirasidars' rights to fruit trees, but as regards untaxed trees in waste, their rights were not different from those of village communities elsewhere.

Further, that the orders regarding Tanjore were based on exceptional rules for the encouragement of tree-planting, which always prevailed there and produced beneficial results: and the Government were decidedly of opinion that no change in the existing practice of the district should now be made. To apply the special Tinnevely rule in Tanjore, or to assert generally the rule that holders of puttas for scattered trees in that district were only entitled to the usufruct, would be entirely wrong.

With regard to the Mannargudi case, the Government observed that the Collector's order did not, as stated by the Board, assign the assessment to the Municipality, but merely waived the Government claim to the small assessment involved, so far as it stood in the way of a desirable public improvement. If the trees, as was probable, belonged to the mirasidars, their rights were no doubt unaffected by the transfer of the trees to the Municipal Commissioners, and they would be entitled to the sale proceeds. But the Government apprehended that the proprietary right of Government in the trees, so far as it arose from the fact of the land being public poramboke, passed to the commissioners under the Act; and unless there were grounds for admitting a private right, the commissioners were

entitled to the trees. In any case, the proceeds could not, and need not, be claimed for Government.

THE Madras Government have recently had under consideration the question of modifying the ~~existing~~ rules in regard to the exercise of the permission to hunt, shoot, & fish in Government forests generally, and with reference to ~~an order of~~ the Nilgiris in particular. In this connection, the following rules, under section 4 (h) of the Madras Forests Act (Act V of 1882), for the Reserved Forests of the Nilgiri District, have been approved and issued by the Government of Madras:—

1. Any person who may desire to hunt, shoot, or fish within the limits of the Nilgiri reserved forests during the season in which such hunting, shooting or fishing is allowed under the Nilgiris Game and Fish Preservation Act (Madras Act II of 1879), and the orders of Government issued under it, shall be bound to take out a yearly pass at the office of the Collector of the Nilgiris.

2. The payment to be made for each such pass will be Rs. 15, and the said pass will not be transferable. It will be available only for the currency of the calendar year to which it relates, whether it be taken out at the commencement of, or during, the year.

3. The Collector may, from time to time, by notification in the District Gazette, declare that any particular reserved forest shall be closed against hunting, shooting, and fishing in any year or during any portion of a year, and after the publication of such notification, no pass taken out under Rule 1, will be held to give authority to hunt, shoot, or fish in such closed reserved forests.

4. The poisoning of water or the setting of traps or snares for game in any reserved forest in the Nilgiri district is absolutely forbidden.

5. Any breach or infringement of these rules will render the offender liable to imprisonment for a term which may extend to six months, or to fine which may extend to Rs. 500, or to both, in addition to such compensation for damage done to the forest as the connecting Court may direct to be paid.

It is to be understood that, as hitherto, the fees will be credited, not to Forest Revenue, but to the Game Preservation Fund.

Mr. Gamble, Conservator of Forests, Northern Division, when recommending the adoption of the above rules, did not think that it would be possible to have one rule for both "reserved forests" and "reserved lands," although, undoubtedly, the different penalties prescribed by the Act in one and the other case constitute a difficulty. He was of opinion that the difficulty would disappear by degrees as "reserved lands" were converted into "reserved forests." The only localities in which, in his opinion, it was advisable to stop the shooting, were those sholas which, having been lately cut over, were now under reproduction, and the plantations, many of which were fenced and easily recognised.

.

A GREAT storm visited Rangoon on Sunday night, and so far as we have been able to learn the following are among the casualties:—The Port Trust police launch *Amie st*, which was at anchor near the Barr-street jetty and was getting up steam, was driven away by the force of the wind and had got well on to the Dallah side before the crew could get her in hand, and she was brought back with all her awnings blown away, and one anchor lost. The Port Trust dredger, which was working near the wreck of the French steamer *Orelon*, sank, and those on board only managed to save themselves by jumping on to the sand-barge alongside. The Irrawaddy Flotilla Company's launch *Olie* broke from her moorings near the Barr-street jetty, and was driven westward till she got caught against the wire moorings of the S.S. *Oriental* alongside the Shoolay Pagoda wharf. In the Avagye quarter of Dallah a barrack attached to a mill in which thirteen coolies slept, came down with a crash, killing one man and injuring all the rest, four of whom were so badly hurt that they had to be brought across to Rangoon for medical treatment. The Station Hospital, in course of construction in Cantonments, collapsed, and the zinc roofing from off several houses near the *midan* was blown away on to the race course.

A cargo boat with 600 bags of rice belonging to Messrs. Strang, Steel and Co. lying alongside the ship *Scottish Dale*, was swamped; as was also another cargo-boat with 1,500 bags of rice belonging to the S. S. *Lo na*. Three cargo-boats belonging to Messrs. J. Q. Rowett lying alongside the S. S. *Madras*, with 1,000 bags of rice foundered, several of the crew being missing. Several godowns in Poozoondoung belonging to millers were unroofed—sheets of corrugated iron flying about like sheets of paper in the air, and carried to great distances. Many Hindoo bazaar boats off the Municipal Bazaar sank, and a European woman and child were picked up between a flat and the paddle of an Irrawaddy Flotilla steamer. The pontoon of the Bassein Jetty was moved out of position; and the Moreton-street jetty was considerably damaged. Not a road but was marked with fallen trees and broken branches. Dalhousie Park looked yesterday as though it had just undergone a bombardment. Some people who were in a boat near the Set Godowns are said to be missing, and also another man, who was upset in his canoe at Kemendine. Several country boats loaded with paddy foundered in the Poozoondoung Creek, and it is feared that several lives have been lost there. These are, we fear, but few of the disasters caused by the storm, and we may expect shortly to hear of a good many more from the district as well as the suburbs of this city.

The following resolutions were passed at a meeting of the agricultural section of the Eurasian and Anglo-Indian Association held the other evening in the Association Rooms, Madras, namely—(1) That the *Indian Agriculturist* or the *Tropical Agriculturist* be subscribed for; (2) that the Agri-Horticultural Society, Madras, be subscribed to; (3) that applications be made to Government or to the Sydapet Farm for an Adu bull for the use of the colonies near Bangalore; (4) that a rain-gauge or barometer and thermometer be procured for the use of the colonies; (5) that arrangements be made by members of the agricultural section to visit the colonies weekly; (6) that the Bangalore Committee be asked to favourably consider the entertainment of a practical man as Agricultural Superintendent on a salary of Rs. 40 per mensem; (7) that a copy of these resolutions be forwarded to the Bangalore Committee; (8) that the next meeting of the Agricultural section be held on the last Wednesday in June.

ALTHOUGH the exports of wheat in 1884 were only two thirds of the amount which left India in the previous year, the demand from Italy, where the Indian grain is valued on account of its suitability for macaroni, continued to increase—upwards of half a million cwts. having been taken from January to December. In 1882 the exports to Italy did not exceed one-third of this amount, and in 1883 were less by one fifth. Exports to Egypt also show a very marked increase during the last few years, and are at present four times as large as the exports to Italy. In 1883 three million of cwts. were transhipped in Egypt, whence a considerable portion is believed to be transhipped to other parts of the Mediterranean coast.

THE Director of Revenue Settlement and Agriculture, Madras, has, we hear, made a proposition that instead of, as at present, basing the whole of the prizes in money to successful competitors at Agricultural Exhibitions, some might take the shape of presentation of stock and of suitable agricultural implements, the nature and kind of the stock being determined by consideration of the agricultural conditions of the districts for which the particular exhibitions are held. By the adoption of this suggestion, the Director is of opinion that stock would, by natural selection, as it were, get into the hands most likely to make the best use of it, and as the stock required for prizes would have to be bought in many places, an impetus would be given to private enterprises in the matter of stock-breeding, whilst at the same time the scheme would in time lead to the better breeds of one part of the country being introduced among inferior breeds in other parts, and thus lead to improvement in that respect. The scheme has the support of the Board, and has been submitted by them for the consideration of Government.

An inquiry was commenced some few days back at the Agricultural Department of the Privy Council which promises to have an important bearing on the future of agriculture in Great Britain. Lord Walsingham presided over a consultation of agriculturists, who

will take evidence as to the best means of preserving green crops by the ensilage process for the use of stock in the winter. It is beyond a doubt that the British farmer's best chance of competing with the foreigner is in the rearing of cattle, and some of the witnesses who have been examined state that they can keep more than double the stock by using ensilage, which has other advantages, such as making sure of securing a crop by harvesting it in all weathers and enabling an extra crop to be had. Some witnesses spoke of substances that were regarded as waste products of the land being greedily devoured by animals, Mr. Harris, M.P., mentioning that the rushes grown in the Devonshire valleys, and used for bedding, were actually eaten after acting as a covering for the ensilage and getting its flavour. The silos for preserving the green crops spoken to by the witnesses ranged from structures specially made to digging a hole in the ground and merely stocking it, sufficiently weighted to extract and exclude the air. Lord Walsingham's agent (Mr. Woods) spoke of ensilage being a valuable auxiliary to dairymen, as it could be sent by rail in casks, and it had actually become an article of commerce, and was sold at Maldon, in Essex, for 50s. a ton. The general scope of the evidence, so far as it has gone, is that the process only required to be known to be generally adopted. Mr. Moffat, agent of the United States Department of Agriculture, referred to the reports to the American Government in the matter, and to a tour in France with Mr. Kalns Jackson, the promoter of the ensilage competition at the Smithfield Club. The Commissioners will recommence their sitting shortly, and evidence will be taken at intervals during the Parliamentary session.

ACCORDING to the *Civil and Military Gazette*, the following rules have been passed by the Maharaja of Cashmere for the regulation of shooting within his territories:—

- 1.—Killing game without a license is prohibited throughout the dominions of his Highness the Maharaja of Cashmere and Jummoo.
- 2.—Licenses can be obtained by Europeans from the officer on special duty and by natives from the Governor of Cashmere.
- 3.—Licenses are not transferable; require renewal annually; and do not give permission to any person employed by the holder to kill game.
- 4.—Killing game is forbidden in the province of Jummoo proper, in that part of Cashmere lying between the Sind and Lidar rivers, and in such places as are, or may hereafter be, reserved by his Highness throughout the country.
- 5.—The destruction of the females of the following animals is prohibited—Bara-Singha, Iber, Markhor, Ovis Ammon, Shapop, Burhal, Thibetan Antelope, Thibetan Gazelle. The destruction of Bara-Singha stag when hornless or in velvet is also prohibited. The destruction of Yak is altogether forbidden in the dominions of his Highness. Any necessary or accidental breach of any part of this rule should be reported at once to the officer on special duty.
- 6.—A close season, lasting from the 31st March (1st Baisak) to the 25th August (29th Sraban) inclusive, has been established for the following winged game:—Moonal, Argus, Cheer, Koklas, and Kalej Pheasants, Black and Chikor Partridges.
- 7.—Licenses may be revoked at any time in case of infringement of these rules.

STATE OF JUMMOO AND CASHMERE.

Licenses to kill game.

To all whom it may concern. The bearer of this license.... is hereby authorised to kill game in the dominions of his Highness the Maharaja of Jummoo and Cashmere, until the end of the year eighteen hundred and eighty-five, subject to the conditions printed on the back.

ON the 9th ultimo, Mr. A. Craikbank, Acting Collector of Anantapora, wrote to the Secretary to the Board of Revenue, forwarding villagewar statements for the taluks forming the Head Assistant Collector's division. He remarked:—"The Head Assistant Collector recommends the remission of the whole assessment on lands on which the crops have failed, or the out-turn was three annas or less, and of half the assessment on lands which yielded from four to eight annas. I see no necessity whatever to alter the scale already fixed by the Board and the Government in the case of the other taluks. The total remissions, calculated according to existing scale, will come to much about the same amount. I am decidedly of opinion that the concessions which have been allowed in the Anantapora, Gogty, and Tadpatri taluks should be extended to the Head Assistant's taluks, for it will be seen from the statements now submitted, that the out-turn in these taluks

was in by far the greater number of cases not more than that estimated by Mr. Galton in his report of the 27th November last, after which there was no rain to do any good. The dewa were scanty and the gram crops did not turn out so well as it was hoped they might do. A good deal of damage was also done to the crops by caterpillars." By the Board's proceedings, dated 11th March 1885, as modified by G. O. 25th March 1885, remission of assessment upon dry lands in the northern taluks of Anantnagar had been sanctioned according to the following scale:—For waste, full remission; for short crop—under 4 annas, full remission; of 4 annas, 50 per cent remission; more than 4 annas but less than 6 annas, 25 per cent remission; of 6 annas and upwards, no remission. The Collector now recommended that this scale be applied to the four southern taluks of the district. His proposals have been sanctioned.

**

The report on the prospects of the wheat crop in the North-Western Provinces and Oudh for the month of April is as follows:—

The area under wheat, according to the April returns which are final, is 5,298,026 acres, showing an increase over March of 13,822 acres, an increase over normal area of 332,348 acres, and an increase over last year of 111,628 acres. Taking normal at 100, the area under wheat in the present year is 106; area under white wheat is 1,217,855 acres, area under red wheat is 2,013,496 acres, area under mixed white and red wheat 2,066,675 acres. The entire crop has been safely harvested, and with the exception of high westerly winds in parts of the Agra and Rohilkhand Divisions, which slightly shrivelled some of the grain, and save hail in a tract of the Bulandshahr district, the weather during April has been most favourable. Taking 100 to represent full average condition, the April returns, which are based on the appearance and weight of the crop harvested, show the condition of the crop after harvesting as follows—517,230 acres at 90; 4,145,873 acres at 84; 634,923 acres at 75. This shows an improvement on the whole compared with the prospects entertained in March. The gross outturn of a full average crop on the area now finally ascertained would be 2,500,000 tons. The present final harvest estimate of this year's crop is 2,100,000 tons or 60,000 tons in excess of the outturn estimated in March. Taking 100 to denote the gross outturn of a full average crop, this year's crop is 84. Of this total crop, 500,000 tons are white wheat, 780,000 tons are red wheat, and 82,000 tons are mixed white and red wheat. Adding the 60,000 tons surplus of the 1883-84 crop, the total stock of wheat in the provinces after the harvest in April was 2,160,000 tons, of which, after deducting food and seed for the coming year, it is estimated that 410,000 tons will be available for export.

**

The report on the prospects of the wheat crop in the Punjab for the month of April is as follows:—

The area under wheat this year is very little in excess of that given in the Revenue Administration Report for the year 1883-84. But it may be assumed that the actual area is really larger. In former statements a large area under mixtures of wheat has been shown as under pure wheat. This year, where the grain of the mixtures is harvested separately, half the area under mixtures has been calculated as under pure wheat. While in those districts where the mixtures are not harvested separately, the area under such mixtures has been entirely excluded from the wheat returns. By the comparative statement accompanying, the difference in area is only—

	Acres.
1884	7,200,600
1885	7,381,400
Excess in 1885	1,71,800

Had the same method of calculation been applied to last year, it is probable that the area under wheat proper would not have been more than 6,000,000 acres. In addition to an increased area under wheat, most reports show that the outturn is generally good. Excessive rain and cloudy weather caused rust in the moister tracts, and the outturn in the unirrigated lands is this year probably higher than in irrigated. There is no reason for altering the report made in April that this year's crop is a full average one. Unfortunately, the recent heavy rains must have done some damage to the harvest. The crop has been almost everywhere cut, but very little has been threshed and gathered in; the greater part is still lying out in the fields and is exposed to storms and rain. It is sincerely to be hoped that bright dry weather will now set in, and enable the harvesting to be completed.

Statement showing area under wheat in each district of the Punjab. In hundreds of acres.

Name of District.	Area in 1884.	Area in 1885.	DIFFERENCE.		Remarks.
			Plus.	Minus.	
1. Delhi	1,415	1,083	..	332	Area under wheat and barley mixed altogether excluded, and that under wheat and gram mixed divided by half this year.
2. Gurgaon	525	513	..	12	
3. Karnal	1,388	1,456	68	..	
4. Hissar	4,087	798	..	116	
5. Ferozepore	..	3,773	Since last year the three districts have been abolished and amalgamated with Hissar and Ferozepore.
6. Rohtak	613	557	..	56	
7. Ambala	2,004	2,004	Statistics not received for two tahsils in Ambala. Area in column 4 given as for last year.
8. Ludhiana	1,776	1,329	..	447	Reduction this year owing to exclusion of mixed crops.
9. Simla	55	35	..	20	Last year's area not reliable.
10. Jullundur	2,296	3,665	1,369	..	This year's area is an estimate. The wheat area this year is greater than usual.
11. Hoshiarpur	3,581	2,575	..	1,006	Reduction owing to reasons recorded for Delhi.
12. Kangra	1,441	1,860	419	..	Increase in area not accounted for.
13. Amritsar	3,435	3,190	..	245	
14. Gurdaspur	3,105	3,850	745	..	
15. Sialkot	3,745	4,048	303	..	
16. Lahore	3,681	3,738	..	173	
17. Gujranwala	2,568	2,580	12	..	
18. Rawalpindi	4,268	5,175	907	..	This year is said to have been an exceptionally good one.
19. Jhalum	3,041	3,040	..	1	
20. Gujrat	3,176	3,281	105	..	
21. Shahpur	2,143	2,174	31	..	
22. Multan	2,879	2,663	..	216	
23. Jhang	1,808	1,841	33	..	
24. Montgomery	1,948	1,940	..	8	
25. Muzaffargarh	1,916	2,065	149	..	
26. Dera Ismail Khan	2,810	2,225	..	585	
27. Dera Ghazi Khan	2,380	1,542	..	838	Heavy damage caused this year by river floods, and area under wheat and barley mixed excluded.
28. Bannu	2,738	2,738	
29. Peshawar	2,777	3,299	522	..	The winter rains came late this year and a smaller area was sown.
30. Hazara	1,225	1,298	73	..	
31. Kohat	995	1,546	551	..	No explanation of increased area yet received.
Total	72,096	73,814	1,718	..	

The following is a summary of the work done in the Cawnpore Agricultural station for the kharif season of 1884:—

The manure experiments show that for kharif crops as for rabi, cow-dung is perhaps after all the cheapest and most profitable fertilizer, as it is most certainly the manure most readily procurable by the Indian cultivators.

In this kharif, as in the last rabi, a thorough inversion of the soil proved decidedly advantageous, compared with the mere piercing of the land with the native implement. It is in the end cheaper and gives a larger outturn for the labour worked.

In the experiment ridge-sowing versus broadcast-sowing of cotton, the country method came off best. But a further testing must be applied before a final verdict can safely be given.

It appears plain that under existing conditions of Indian cultivation, it is a distinct disadvantage to take two crops of cotton from the same plant. It is better to take the one crop, and then plough up the land in the spring either for another kharif crop or a cereal in the following spring.

New Orleans cotton failed. But there are other varieties which remain yet to be tried, and the successful introduction of an exotic cotton of a more marketable kind than the indigenous variety is not to be despaired of.

In regard to maize, which is a very important crop, it is proposed to attempt in the coming kharif the American method of sowing in hills or squares. The secret of the success of this process lies in the free ventilation and sunlight secured to the plants. The success of the "hill" or "square" cultivation in America has been remarkable.

The ensilage experiment is still on its trial. If the fodder proves really serviceable to working cattle, there seems every reason to believe that ensilage may yet become an institution in India. The whole cost of the silo up to packing and filling is less than the cost of digging and lining an ordinary well, so that on the score of expense the cultivator cannot well complain. [This part of the report has been noticed separately elsewhere.—Ed., I. A.]

The matter of ploughs is not an easy one. The same fashion of plough does not suit all soils and all sorts of cultivation. Experience, however, is being gained, and the Duplex plough will shortly be put to a practical test elsewhere.

MR. EDGAR VINCENT, in his report on Egyptian Finance, makes the following remark in regard to irrigation in that country :—

"Considerable prejudice exists in Egypt on the subject of water rates. The Government has so often broken faith with landed proprietors by imposing taxes for water and not giving any water, that great difficulty would be encountered in an attempt to increase the revenue by an impost of this nature."

A contemporary, in noticing this subject, makes the following very appropriate observations, in which we generally agree :—

"If the name of India were substituted for Egypt, these remarks would come home forcibly to the Government of this country. Since the day when the Irrigation Department was first established, it succeeded in gaining the name of the 'Irritation' Department. If the officials persuaded the land-owners to pay in advance for a supply of water, they irritated and possibly ruined them by giving no water when it was most needed. If they allowed the cultivator to help himself to water on credit, there was a day of irritation awaiting the officials when they tried to enforce their demands, accompanied by no little irritation to the cultivator, because of the manner in which the demands were pressed. It appears from Mr. Edgar Vincent's report that he proposes to re-assess the land tax *de novo* on lands of which the value for agricultural purposes has been sensibly and permanently increased by new irrigation works. This may answer very well in the Government domains in Egypt, but in Lower Bengal where the Government has introduced irrigation works for the benefit of lands against which the demand for revenue may not be enhanced under the Perpetual Settlement, it is left to the awkward alternative of irritating the zemindar by making him pay for the cost of the new works, or of irritating both zemindar and ryot by a direct demand for a water-rate on behalf of those who use the water. The demand may be just—but when the zemindar and the water-rate collector are both attacking the ryots' pocket simultaneously, there is sure to be more irritation than is desirable for the good of the people. No doubt, therefore, as Mr. Edgar Vincent observes, a considerable prejudice exists in India as well as in Egypt, on the subject of water-rates."

MR. M. A. LAWSON, Director of Government Cinchona Plantations, Parks and Gardens, Nilgiris, has submitted the following report of the causes which have led to so marked a falling off in the receipts from the sale of Cinchona seeds and plants :—

First.—In former years when the cinchona industry was in its infancy and a large number of plantations were being opened out by private growers, there was necessarily a very large demand for cinchona seed and cinchona young plants ; and as the Government plantations were the oldest and most noted in the district, the growers naturally applied to Government to supply their needs. This went on for several years, until the new plantations were able to supply their owners with what Government before had only been able to produce. Again, these new plantations are now able to compete with the Government in the sale of seed and plants.

Secondly.—Owing to the great depreciation which has recently occurred in the value of cinchona bark, the public have been deterred from increasing their plantations, or from opening new ones.

The general result of these two above-mentioned circumstances has been a very small demand for Government seed and plants.

The following table shows the miscellaneous receipts for the past eight years :—

			Rs.	A.	P.
During 1877-78	2,431	2	3
" 1878-79	8,136	9	2
" 1879-80	12,300	6	7
" 1880-81	13,175	4	8
" 1881-82	6,048	1	5
" 1882-83	4,200	7	10
" 1883-84	4,352	6	8
" 1884-85	1,527	10	5
Total	52,562	1	0

The explanation given above is considered "satisfactory" by the Madras Government.

THE following is a summary of Wm. Jas. & Hy. Thompson's Fortnightly Circular of India Tea, dated Thursday evening, 7th May, 1885 :—

Since the date of our last report, 14,500 packages have been catalogued for sale, 2,800 packages of these being Ceylon Tea, and 900 packages reprinted and second-hand parcels.

There was a brisk demand last week up to the date of the Budget announcement, and upwards of 11,000 packages were sold at full rates, the market being sensibly affected by the extensive purchases of retailers, which were being made until the last moment, in order to pay duty.

Subsequent transactions have been very light, only 2,800 packages, principally Ceylon Tea, having been sold this week, and with the pause in business the tone has become quiet ; prices, however, are well supported by the competition of those who are anxious to replenish their stocks.

The April Deliveries of Indian and Ceylon were 8,704,000 lbs. as compared with 4,990,000 lbs. last year, which, added to the March delivery, makes a total of nearly one month's consumption taken from the warehouses above the ordinary average ; while duty has been paid (on tea in the aggregate) more than two months in advance of the usual amount. Stocks in the warehouses are now 9 million lbs. less than a year ago ; this deficiency, however, will be reduced during the next two months, as the clearances during May and June will probably fall considerably short of the quantity cleared last year, viz., 10,500,000 lbs.

China tea is in a similar position, the stock being 22 millions less than last year—and as much as 34 millions less than in 1884 ; prices, however, are hardly at all affected, and the market continues quite devoid of animation.

MR. HAVEL, Superintendent of the School of Arts at Madras, has submitted a report of his enquiries into the arts and industries of certain districts which he was ordered to visit shortly after his appointment. The districts visited were North Arcot, Salem, Tanjore, Trichinopoly, and Madura ; but Mr. Havel does not report favourably of the arts and industries there. He discovered nothing new, but he made a valuable collection of specimens of weaving, spinning, cloth printing, metal work, wood-carving, and pottery, which is to be retained in the School of Arts for teaching purposes. He considered that the condition of the arts and industries was decidedly unsatisfactory, for, as Mr. Havel says, not one of them can be said to be thriving, while some appear to be fast dying out. This he attributes to the influx of cheap machine-made articles from Europe, which the general body of the people readily appreciate ; and to the spread of European education and ideas. Mr. Havel suggests that the present collection at the School of Arts, together with the collection which he had lately made, might prove the nucleus of an Art Museum for the Presidency, which he thinks would exercise a most important influence upon native art. The question of the formation of an Art Museum has not yet been formally brought under the consideration of the Local Government ; but Mr. Havel has been directed to make another tour in other districts during the next cold weather, and a further collection of specimens.

A CONTEMPORARY learns that the Horse Show and District Fair which was held at Alighur from the 9th to the 14th of February last, is reported to have been the most successful that has ever been held there. One particularly noticeable feature in the fair was the large number of mares and fillies brought to be branded during the Show, which proves the increased demand that is growing up in the district for the use of the Government stallions, and also gives promise of an improvement in the breed of horses in the district. In consequence of this, the Government prize for branded mares and their produce will be increased in future by the addition to them of the bulk of the district prize fund, the remainder of that fund being chiefly allotted to ponies, a few special prizes being allotted to private-bred horses of distinct merit. Altogether there were 953 country-bred and 183 Cabuli horses, against 683 and 412 at the last Show, whilst 36 remounts were purchased as compared with 8 last year. This number of remounts would probably have been exceeded, but the officers who came to purchase complained that many of the horses best suited for their purposes were not for sale. The highest price paid for a single animal was Rs. 500 for a three-year-old colt, which certainly may be said to be a satisfactory price. The total value of the horses which changed hands is given at Rs. 15,151. As to the other part of the Fair, it appears to have been generally successful, as there were 171 shops opened, against 128 in the previous year, and the dealers are said to have been satisfied with the results of their sales. The show of carved wood, muslin, cotton cloth, and cotton carpets is reported to have been extremely good, and, in the two last branches, a distinct advance is said to have been made on the former standard of manufacture. The exhibition of live stock, agricultural produce, and agricultural implements was a comparative failure, although they were expected to be among the chief objects of attraction.

SUGAR CULTIVATION IN INDIA.

(Continued from last week.)

The *Produce Markets' Review*, some 3 or 4 years ago, estimated the outturn of sugar-land in India on an average at 8 cwts. of unrefined sugar to the acre. But the figures we quoted in the last paper on this subject, established the broad fact that the yield is considerably more than the *Review* estimated, which fact was accordingly reported to the Secretary of State by the Government of India. Attention was, at the same time, drawn to a memorandum on the subject prepared and submitted by the firm of Messrs. Thomson, Mylne & Co. who, as large landowners, devote much care to the improvement of indigenous methods of sugar cultivation and manufacture. In this memorandum, it was stated that the average yield of an acre of carefully cultivated land, was 1 1/10 or 1 1/5 tons of crude sugar. This, it will be observed, corresponds closely with the average of 23 cwts. given for many districts in the North-Western Provinces and Oudh, and the Government of India were inclined to think that this was as close an estimate as could be made. We also incline to this view, and cannot think from what source the *Produce Markets' Review* got its information. Though this yield is considerably less than the 2 or 2 1/2 tons which a sugar plantation in the West Indies is said to yield, it does not afford evidence of such extreme inferiority in the sugar-cane cultivation of this country as the *Review* would seem to imply. Of course, exceptional intelligence and capital are employed in this industry in the West Indies, but apart from this consideration, the climatic conditions of India are not quite as favourable to the cane as they are in the West Indies.

We now come to the mode of manufacture practised in India. It must be admitted, in regard to this, that the native methods of expressing the juice and manufacturing sugar, are not only of the most primitive, but of extreme crudeness and simplicity; and, in many respects, inefficient and wasteful. Some improvements have, however, been effected in respect to sugar-mills, which have been noticed in these pages from time to time; and the establishment of large sugar refineries in various parts of the country will gradually tend to better methods of manufacture. But even with the present imperfect

methods, the Government of India have ascertained that the profits of the native sugar-growers and manufacturers are large; and that crude Indian sugar, though unsuitable in the London market, finds a ready sale among the natives of the country. It may be observed here, that the natives, to whom a refined, crystallised state has been, and is, unknown, do not look for it in that state, and are quite content with its commodity in its crude conditions of *gur*, *raff*, and *khands*. To this circumstance is to be attributed the ready sale with which it meets in the Indian market, and by which the native growers and manufacturers realize such large profits. It has further been ascertained that the price has risen rapidly within the last decade; while in the markets of Northern India, the present wholesale price of undrained sugar, or *gur*, is Rs. 4 1/2 to Rs. 5 the cwt. In the returns for Bengal, much higher prices than the above have been shown against many districts, but in these cases, as already noticed, the produce has been returned in refined sugar, and the price of that description of the article given.

The difficulty of arriving at the total annual production of sugar in British India is much felt by Government. It may, however, be asked, why? If the proper agency is employed in collecting accurate statistics, there is no reason why we should not have as correct information on this as on any other subject. As a matter of fact, the attention of Government has only recently been directed towards this important industry, and consequently when it called upon the various local Governments and Administrations for information on the subject, nothing of the kind ever having been required before, they were unprepared, and the information supplied was necessarily of an imperfect character. Had not the *Produce Markets' Review* called attention to it, and thus attracted the notice of the Secretary of State for India, who in his turn called upon the Government of India for complete statements, the probabilities are that matters might have remained in their pristine condition to the present day. Accepting, however, the figures given in the returns of the area under cane, and assuming the average yield to be some what under 1 1/10 tons of crude sugar to the acre, we have a gross production of about 2,000,000 tons. Add to this, the produce of the 168,262 acres of palm trees, which may be set down at 150,000 tons. The foreign trade returns show that the supply is not equal to the demand. The Government of India have ascertained that the quantity of Indian sugar exported to England, Ceylon, and elsewhere fell off considerably within the five years from 1876-77 to 1880-81, as will be apparent from the figures quoted below, which give the value of the total sugar exports from Indian ports during those years:—

	£
1876-77	925,196
1877-78	745,551
1878-79	204,360
1879-80	265,571
1880-81	311,750

On the other hand, the sugar imports rose from £403,556 in 1870-71 to £160,167 in 1880-81. The greater part of this sugar, it is said, came from Mauritius, and its consumption appears to have been confined to the Bombay Presidency, where comparatively little cane is as yet grown.

The gross exports of sugar in 1880-81 is put down as having been 534,174 cwt., and the gross imports 286,321 cwt. The net import, therefore, was about 23,000 tons. But as the exports were confined to raw sugar, while the imports were refined sugars, the excess of the imports over exports must of necessity have been greater than appears from these figures. In explanation of the dependence of India on other sugar-growing countries, the Government of India observe that many parts of India are unfitted for the cultivation of the cane. The Bombay Presidency, it is said, has to supply itself from Mauritius, while Rajpootana and Central India consume the surplus produce of the North-Western Provinces and the Panjab. They do not, however, consider that the increasing import and decreasing export indicate the decadence of the industry in India. Up to 1882 the area under cane had greatly increased in Upper India through the development of canal irrigation, and it was reported to be extending from the same causes in Bombay. The conclusions arrived at by the Government of India were, that more sugar is produced in India

than formerly; but that the demand was much greater; that not only had the increasing prosperity of the people enhanced the average consumption, but that sugar is now borne by rail into tracts where the cane is not cultivated, and which were formerly very scantily supplied; while the profitability of the industry was evident from the high price which the Indian agriculturist obtains for his produce. And lastly, that all the evidence before the Government of India led them to the belief that the capital invested in sugar cultivation in India was steadily increasing. In these conclusions we generally agree. The papers before us are not sufficiently complete to admit of a critical examination of the subject; but later correspondence has been courteously promised, on receipt of which we hope to go more fully into the matter.

INDIAN LINSEED.

THE Indian public are probably familiar with the paradox that it is difficult to make iron in this country because the trees are so rich. We are now indebted to the India Office for the information that Indian linseed is beaten out of the market at home, because it yields so much richer an oil, than the common Baltic linseed used by the painter and the manufacturer of floor-cloths and linoleum. On the 9th January last, the managing director of the North British Floor-cloth Company at Kircaldy wrote to the Under-Secretary of State for India as follows:—

It may interest you to know, if you are not aware of it, that a very large amount of linseed oil is used by the manufacturers of floor-cloths (wax-cloth), linoleum, &c., apart from the general painters' work, and that all these not merely prefer but pay a much higher price for Russian called Baltic, linseed oil in preference to Indian or Calcutta linseed oil, the reason being that the Indian seed oil is considered to be too fat, or rich, and devoid of the more readily drying quality of the poorer oil obtained from the Baltic seed oils. Calcutta seed oil is plentiful and cheap, whilst Baltic seed oil is scarce and dear, and I think I pretty nearly give the respective value at £22 to £19 10s. per ton for Calcutta and £23 10s. to £24 per ton for Baltic linseed oils.

In this comparatively small town, the seat of the floor-cloth and linoleum trade for Scotland, not less than from 50 tons to 60 tons of linseed oils are used weekly. Of course the manufacturers in London, Manchester, and Lancaster, &c., must use a very large quantity, all doubtless preferring and paying a higher price for the better quality of oil. No doubt agriculturists prefer the richer quality of linseeds for cake for feeding purposes. Perhaps the Indian growers of linseed, were they aware of the higher prices obtained for the Baltic or poorer oils, could readily grow, and at smaller cost, linseed that would serve the purposes for which Russian seed is so much preferred, and for which so much more money is obtained for the oils.

Now, here is one of those great economic facts which show the vital necessity there is of close observation and research in all departments of the agriculture of the country. There are probably not less than 500,000 tons of seeds exported from India every year, and it is perfectly startling to hear of our linseeds selling for £5 a ton less than the poorer seeds of Russia, because of the very richness of their quality. If the Indian seed commanded but the same price as the poorer Russian qualities, the country would be better off by a million sterling a year. On the 10th January, we read that Mr. MURRAY of Dokerie-Crief addressed the India Office on the same subject as follows:—

You will have noticed that the commercial papers of Manchester and Glasgow frequently published short extracts from the reports on produce. These reports are, however, generally one or even two years old, and though curious as history, are commercially useless. The managers of these papers are, I believe, anxious to give information. The Dundee Advertiser has a special correspondent in Calcutta to write news about the Jute trade, but he appears to be a broker, who really knows nothing but jute.

The price of your rupee bills depends not on the past history of India, but on the daily price of jute, wheat, silk, indigo, peas, &c. The commercial world want to have daily news about prices in India, just as they have about America.

I am told by Mr. Aytoun, Manager of a large Floor-cloth Work at Kircaldy, that they use fifty tons a week of linseed oil, but that they find Russian oil best; the East Indian linseed is too rich and does not make a hard surface. I have told him how I found it possible to harden East Indian linseed oil by adding rosin to it. This seems unknown here and keeps down the price of East Indian linseed, one of these apparently small details that turn trade. At the same time the cake made from East Indian seed is best for cattle feeding but is not much used at present; the oil in the article that leads the market. I believe you will find the commercial papers quite ready to help in advertising the articles you want to sell.

Now it is quite conceivable that the Indian ryot by sowing upon poorer soils, or by a change of seed might be able to produce precisely the kind of seed which the European manufacturers require. It often strikes us that the waste of the present age must be incalculable, from the want of a 'thinking' department in the affairs of life. Nothing is so painfully conspicuous in modern government or administration, as it is generally called, as the want of leisure for 'thinking.' Men of the most brilliant powers, say, Mr. GLADSTONE, pass their lives under the pressure of such a torrent of work, that they have no time for reflection; for 'thinking,' whatever. It is the same in our merchants' offices. The master and his assistants are absorbed from Monday morning till Saturday night, and too often on Sunday as well, in the drudgery of hard routine work, that leaves them no time whatever for calmly and fixedly concentrating their attention upon the circumstances, the conditions under which their work is carried on. A frantic sort of activity has come upon us all as a necessity, and we work like horses put into the shafts every morning to work all day, until tired out at night, we lie down upon our beds. That the activity of the age is unwholesome, excessive, and morbid, we have felt painfully for many years, and it is even worse in England than in India. It is impossible to mistake the meaning of the hurried gait, and anxious face of every one you pass in the city. The weight of Atlas is upon the shoulders of every man, and he has no time for thinking. The man who thinks is lost. A happy reflection, or idea, seizes some man's mind in the course of his business, not because he has patiently concentrated his attention upon it, but by pure accident—and his fortune is made. Were but a little time for thought and observation secured, we should soon cease to find linseed grown of too rich a quality in India.

A BLACK CLOUD WITH A SILVER LINING.

"A BLACK Cloud with a Silver Lining," is the heading of a paper in the *Pall Mall Gazette*, giving Mr. Moreton Frewen's views on the Silver question. We do not mean to take up that intricate question at present, but give the following extract regarding the Indian ryot, to shew the fallacy of the writer's argument:—

"That will be the position of the Indian revenue when the rupee has lost still more of its present shrunken value? Take the land tax, a fixed annual payment in Rupees. Formerly the rupee was worth about a florin; how is the revenue deficit to be made good, when the florin has become a shilling? And what will the ryot do? Formerly he exchanged, say six pounds of cotton for a rupee, and ten rupees for a sovereign—that is, for a sovereign's worth of Manchester cotton goods. Now, with this depreciated rupee, if he still exchanges his six pounds of cotton for the rupee, and twenty rupees are required to buy a sovereign, he will have to produce not 60 but 120 pounds of cotton to buy the manufactured goods. So the Indian can no longer buy from Manchester, and the cheapness of raw cotton not being followed by the ordinary demand for the manufactured article, the Manchester spinner must close his mill."

The ryot's standard of value is the rupee, and it does not matter to him whether it requires ten or twenty rupees to buy a sovereign. The price of silver is less to him than the price of gold, and is not a standard measuring the value of the cotton he produces, or the cost of the Manchester goods he consumes. The following figures taken from a Bombay price current will shew that the rupee prices of cotton and Manchester goods have not followed the movements of silver, with that fidelity in the past which Mr. Frewen predicts for the future:—

BOMBAY.

1887.	Exchange 4 m/st Bill.	English Gold.	Dhollerah Cotton.	8 lbs Grey Shirtings.
	per Rs.	per t/wh. Rs.	per candy Rs.	per piece. Rs.
April ..	1/11 1/2 to 9	16-10	215-245	6-12 to 6-15
October ..	1/11 1/2 to 1/11 1/2	16-12	155-175	6-11 to 6-13
1876.				
April ..	1/8 1/2 to 1/8 1/2	18-5 to 18-6	170-175	4-12 to 5-12
October ..	1/8 1/2 to 1/8 1/2	18-10 to 18-12	168-175	4-12 to 5-8
1884.				
April ..	1/7 3/4 m/st bill	19-10	200-220	3-8 to 4-12
October ..	1/7 3/4 to 1/7 1/2	19-14	170	4-8 to 4-12

Cotton, however, is not the only produce for which the ryot gets rupees, and the following table taken from a circular issued by the Bengal Chamber of Commerce, shows that other staples of export have no more followed the lead of silver than cotton has done in Bombay:—

CALCUTTA.

	8 lb. Grey Shirtings.	Rice.	Jute.	Wheat.	Linseed.	Cotton.	4 m/et B. Bolls.	Gold Australian.	1867.
		per md.		per md.	per md.	per md.		per tolab.

The depreciation of silver has been of great benefit to the ryot by cheapening, as it undoubtedly has done, the *starting* cost of his produce, and increasing his customers, while at the same time extended railway communication and the Suez Canal have accelerated and cheapened transit, since the days when a rupee was worth a florin. A glance at the above figures will show that now-a-days the ryot, as a matter of fact, gets as many, if not more rupees for his cotton and produce, more yards of Manchester cloth for his rupee, than he did in the halcyon days of two shillings per rupee exchange.

The abolition of import duties, cheap transit, and the competition among European merchants, whose commissions are just one-fifth of what they were in 1867, have combined to cheapen to the Indian consumer, not only his clothing, but everything else he wants from Europe, with the single exception of gold. Gold is a luxury for which he can easily afford to pay, and is willing to pay, as the increased imports of the metal in the last few years show. It may be advanced that if silver were dearer, or exchange at two shillings, the consumer would benefit the more. We do not, however, concern ourselves with speculations at present,

but call attention to the cotton culled from the dry reading of commercial reports.

The important fact which faces us in the face, in considering this question, is the position not of the ryot, but the position of Government in view of the further depreciation of silver, which the abolition of the Bland Bill in America would undo.

There will be a large increase of warlike expenditure to be during this financial year, and as this expenditure may be looked upon as an insurance premium paid for peace, to enable the ryot to cultivate his produce and consume his Manchester goods in comfort, the ryot should pay the premium. In the 19 financial years from 1866-67 to 1884-85, the net imports of gold and silver into the country aggregate 168 crores of rupees, and the figures for the past four years are somewhat startling:—

	NET IMPORTS.		
	Gold.	Silver.	Total.
	Ra.	Ra.	Ra.
1881-82	4,84,89,242	5,37,99,699	10,22,88,941
1892-83	4,93,03,715	7,48,02,289	12,41,10,984
1883-84	5,46,83,166	6,40,61,640	11,86,94,806
1884-85	4,67,83,868	7,24,53,254	11,91,92,122

What becomes of all this wealth, may be asked? It does not go to build railways, make canals, or encourage any enterprise of public utility, or benefit to the country, but goes mostly in the manufacture of jewellery or is hoarded up. The fact that the Raja of Burdwan has some nine crores of Rupees lying idle in the vaults of his palace, proves hoarding, a practice which is followed largely not only by the independent Princes, but also by all classes in the country.

There is some talk of an income-tax, but past experience has shown how unprofitable and how difficult it is to collect, and we are of opinion that the increased produce of the land should pay more than it does now. We do not advocate export duties, which would handicap the producer in the race with other countries producing cotton, wheat, and seeds, but we do advocate a return to import duties as a financial expedient.

When the salt duty was reduced, it was looked upon as a reserve to be drawn upon for famine or war expenditure, being easily collected. The reduction of duty has not increased the consumption to a greater extent than the increasing prosperity of the country justifies, and a considerable increase of duty would not curtail consumption. Gold as a luxury should be heavily taxed, and an import duty on silver is due to a Government which has to meet its obligations for the benefit of the country in gold. The relative value now of cotton and Manchester goods, as compared with 1867, points to the latter as a fit subject for an import duty. Import duties are easily collected, and are fairly distributed over the classes who reap the benefit of the stability of the Indian Government.

NOTE.—The statistics in this article are most valuable, and must have occasioned much trouble to the writer. With some of his conclusions, we agree fully, but there are others which we cannot accept.—ED., J. A.

EMIGRATION FROM INDIA.

THE Resolution of the Bengal Government on the Colonial Emigration Report for 1883-84, published in the *Calcutta Gazette* of the 7th instant, furnishes some interesting particulars, on the subject of emigration from India to the Colonies, for which special facilities were offered by the Government during the year under review. The health of the emigrants was cared for, and the voyages were arranged that they might arrive at the Colonies at the most healthy period of the year. There were eight Agencies at work during the year, as in the previous year. The British Colonies of Mauritius, Trinidad, Fiji, St. Lucia, Demerara, and Natal all imported emigrants from India, and the Dutch Colony of Surinam and the French Colony of Guadeloupe also had their share. The total number called for by the nine Colonies was 17,064, and the total number forwarded was 10,260, being 6,979 short of the requisition. The following table shows the numbers required by each, and the numbers actually despatched:—

	Under requisition.	Despatched.
Demerara	6,000	2,537
Trinidad	3,205	2,470
Fiji	2,100	1,401
Mauritius	990	1,135
Natal	1,824	475
Surinam	1,800	1,355
Guadeloupe	900	685
Jamaica	400	none
St. Lucia	775	none
Total	17,064	10,260

INDIAN AGRICULTURIST

Abstract

JOURNAL OF INDIAN AGRICULTURE MINERALS AND STATISTICS

WILMINGTON - SATURDAY, JUNE 20, 1992

THE NEW YORK TIMES

ALL INFORMATION CONTAINED HEREIN IS UNCLASSIFIED

General weather during the month has been throughout the Western States, and especially here, slightly improved in the west-central portion. In California, where winter wheat is reported to be up to the ear, the current season is seven weeks late, or more. The average rainfall below the average is near 2 inches. There has been a slight rise in the Upper Nile, improving the crops and facilities for irrigation operations. In Iraq good rain has fallen, and ploughing has been commenced. In Bombay rain has been general, and the wheat crop has commenced in place.

Wheat has not fallen in two of three places in the Punjab but more in the Punjab, Western Provinces and Oudh. The rice has been harvested in the Western Provinces and liber operations are in good progress. There is no general Provinces more rice has fallen in most districts. Harvest operations continue, and sowing have commenced. Good rain has fallen in the Bihar and Utkal, and in the Central India and Madhya Pradesh States, and agricultural prospects are generally favorable.

There is some rain fall in all districts of Bengal Proper, but rain still is scarce in Calcutta, and there have been only slight showers in Orissa and Chota Nagpur. The rain has been of some benefit, but much more is still wanted for the rice, jute, indigo, and the other crops; and for the maturing of the sugar crop generally, as well as for the growing of the cotton in Bihar. Rain continues to fall in Assam, and ploughing and sowing are now in progress. Red spider and blight are reported to be doing some damage in Cochin.

Prices are stable, except in Bengal, where they show an upward trend.

Work on general prospects fair; slightly improved in Bohary and
Ludlow. Mill work will be stopped by end of June, if season

Deaths.—None throughout the Presidency. Propagation for thirty years, in small districts; thirty working in progress in parts of Mexico, Central, and California; scarcity of drinking-water in two, and in others, the absence of them. Cholera in parts of sixteen, small and the cause of deaths, and typh and pestilence in parts of eight.

Heavy rain has fallen in all districts of Bengal Proper, except in the districts of Dacca and Chittagong; rain still holds off in Behar and Orissa, but slight falls in Orissa and Chota Nagpore. The rain has been much needed for the safety of the crops, for the filling of the tanks, and for the cultivation of the rice, as well as for the sowing of the kharif crops. The rain has been steady all over the province, with a tendency to be more abundant in the north than in the south. The rain is generally spoken of as fair, and has been abundant in several places, owing to intense heat. In the districts of Dacca and Chittagong, the rain has been reported to have been very heavy.

of food grains slightly more. But the Government has

Silver and Hydrated—*Staphylococcus aureus*, *Staphylococcus pyogenes*, *Cholera in Shanghai* (with an Atlas of Bacteria and Fungi).

Central India Region: Washan shik gull nesting

Respectable.—Weather very hot. Cholera epidemic still present, but not in epidemic form. Health good.

Report.—Weather hot; rain wanted. A few signs of showers in the valley.

Letters to the Editor

SEEDLING FROM TRUTH

1. The first step is to identify the problem or question that needs to be answered. This involves understanding the context and the specific requirements of the task.

Letters to the Editor

SEEDLINGS FROM WILDS

Sir, - I have the pleasure of acknowledging the receipt of your letter of the 11th inst. in relation to the matter of the release of the slaves of the ship "The *Amelia*", which vessel was captured by the British privateer "The *Amelia*" on the 11th inst. I beg to offer a few remarks on the subject. The vessel was captured on the 11th inst. and the crew released from custody.

The general belief among entomologists, that amongst grown from seeds, the fruit of the mango eaten, invariably produce inferior and diseased fruit, the cause which they assign for this is, that the seeds are affected by the action of the soil, and are poisoned by it, is inexactness. If we accept the malaria theory, how is it then, that seeds of mango produce inferior fruits, though the pulp has either been removed, or is so

ed, without the seeds being touched with the soil. The native theory is nothing but a superstition, common among the ignorant natives and even among the educated put forward by the ignorant, uneducated natives. These natives are and cultivators, who do not know how to sow the seeds and for such seedlings, to sow seeds in the soil, to dig pits for sowing or transplanting seedlings, to prevent deterioration in mango seeds, and how to sow and rabbit's dung well together in water and about the seedlings.

with others at well known points in the river. It is possible that some of the points in the river are being used as a base for the operation of the river. It is also possible that the river is being used as a base for the operation of the river. It is also possible that the river is being used as a base for the operation of the river.

1990

1. The first step in the process is to identify the problem or issue that needs to be addressed. This involves gathering information and understanding the context of the problem.

Editorial Notes.

We hear that Mr. M. Finucane, C.S., the newly appointed Director of Agriculture, Bengal, has lately returned from Darjeeling, and is engaged in organising the new Agricultural Department under the Local Government.

THE Civil and Military authorities in Madras have been discussing the question of control over certain stone quarries situated within the limits of the Bellary Cantonment. After a lot of unnecessary correspondence, it has been decided that the control is to be vested in the hands of the Military authorities. But red-tapeism must run its course!

THE *Farmer's Review* says that the latest cure, or kill, for the cabbage worm is ice-cold water liberally sprinkled on the heads during the heat of the day. The worms, it is claimed, under this cold-water treatment, curl up, roll to the ground, turn up their toes, and die, while the cabbages themselves are all the fresher for the treatment. The right temperature of the water is readily maintained by keeping a good-sized piece of ice in the sprinkler. Cabbage growers will do well to *paste* this in their hats.

THE preservation of timber is a matter of much importance in India; and the following might be noted by those interested in the subject:—A farmer, writing to one of our American contemporaries, says that twenty-five years ago he set split white oak posts for his garden fence, putting about a peck of air-slacked lime about each, and they are all good yet. He attributes their good condition to the effect of the lime, in which he is doubtless correct. A board that has been used in a mortar bed, and thoroughly saturated with lime, is almost indestructible from decay. An addition of salt to the lime would, we think, if possible, give still better results in preserving the wood.

We see that the Land Improvement Loans Act, XIX, of 1883, came into force in the Punjab on the 1st instant, and the new rules for its application have been published, and the Local Gazette. Under these rules, Deputy Commissioners are empowered to grant loans, not exceeding Rs. 1,000, for any one improvement, and loans above that amount will require the sanction of the Commissioner; but if the sum exceeds Rs. 5,000, the sanction of the Financial Commissioner becomes necessary.

THE prospects of the indigo districts in Bengal are more favourable. Good rain has fallen throughout Krishnagar, Jessore, and Midnapore. The ultimate result of the season will now depend a great deal on an early or late inundation. The reports from Moorshedabad are not so favourable, as rain in that district has been only partial. Rain is still badly wanted in most parts of Behar, though during the last few days the weather had become unpleasant, and rain was expected. No fresh news has been received from Benares or the North-West Provinces.

THE reports from the tea districts state that the weather generally in Assam had been too cold, and sun was wanted to encourage the flushes. Rain was, up to a late date, also much wanted in Cachar and Sylhet; but according to the latest news, some good rain has since fallen, which may help to clear off the blight in Cachar where it has been very prevalent. There has also been heavy rain in the Terai and Darjeeling districts, and this will help to clear off the red spider and green fly, from which a large number of gardens have been suffering.

THERE is such a desire in the breast of the ordinary government official to tax salt, that even the salt used for curing fish was not exempt. It is, however, satisfactory to learn that "on reconsideration" the Government of Madras have come round to the opinion that it would be better to forego all duty on salt used for curing fish, having regard to the advantages to the public which will accrue therefrom. The Government even go further, and have ordered that the present system of supply at

cost price is to be continued; and the Revenue Department is to make it a point of suggesting measures for extending the benefits of the system.

THE following is a summary of the usual Monthly Return of Shipments of Tea from Calcutta, issued by the Indian Tea Association:—

	1885.	1884.	1883.
	lbs.	lbs.	lbs.
Exports to Great Britain in May	1,275,816	718,627	277,386
Exports to Australia and New Zealand in May	22,699	5,120	5,018
Exports to America in May	40	2,980	2,925
Exports to other places in May	8,561	8,898	14,515
Total Exports in May	1,306,606	736,625	305,824

The increase in 1885 is remarkable. It would seem that the Americans are not great tea-drinkers, at any rate they don't seem to patronise Indian Teas to any great extent.

We publish elsewhere a Resolution by the Local Government, on the distress said to be existing in certain parts of the Moorshedabad district. We are very glad to believe that our district officers are watching the condition of the people carefully. We have no means of verifying that condition ourselves, but that suffering is very wide-spread in the provinces, there can be no doubt, and it is idle to complain of our public officers being "set upon useless investigations," with such testimony as that of Mr. TAYLOR and Mr. COXHEAD in our hands. At the same time, we would urge the correspondents of the Press to shew more care than they sometimes do, in verifying the stories they send to the papers. The *Bungabasi*, in the present case, might enquire, we think, of its correspondent, how he came to exaggerate so greatly the distress in the Kargram thanah.

We have before us a report by Mr. C. Benson, Agricultural Reporter to the Government of Madras, on a letter written by Mr. C. Kristnasawmi Mudaliar, in which he describes his method of cultivation with improved ploughs, and the cost incurred by him in his several experiments. His letter is an interesting one, and consists mainly of answers to certain questions put to him by the Agricultural Reporter. Mr. C. K. Mudaliar has proved himself to be a practical agriculturist, and has well earned not only the gold medal presented to him by the Government of Madras, in recognition of his successful efforts towards agricultural improvement, but the badge of a Companion of the Order of the Indian Empire, conferred upon him by the Viceroy. We trust that this public recognition of Mr. Mudaliar's services to agriculture, will induce other private landholders to emulate him in this direction.

We are very glad to find that the Madras Government have accorded their approval to a proposal of the Director of Revenue Settlement and Agriculture, to substitute presentations of live and dead stock for the money prizes, which it has hitherto been the custom to distribute at Agricultural Exhibitions. This is a move in the right direction. In a scheme like this, which has for its object the improvement of stock, and the encouragement of those engaged in stock breeding, it is to be expected that the Government will have to spend large sums of money at the beginning, without anticipating anything like an appreciable return for a very considerable time to come. Let us, however, hope that the advantages that will accrue to the country will be a sufficient return for a time at least. Improved cattle and machinery in agricultural pursuits mean improved cultivation and revenue, and a general improvement in the condition of the people.

FOREST Conservancy in the Tanjore District does not appear to have worked satisfactorily. The revenues from this source have been getting "smaller by degrees and beautifully less." They have sunk from Rs. 13,000 in 1881-82, to Rs. 6,971 in 1882-83, and to Rs. 4,408 in 1883-84; while the current year's estimate of Rs. 10,000 is expected to fall short by Rs. 2,000!

while its sources, as pointed out by the Conservator, are distinctly of a non-permanent character. So that, having regard to the requirements of conservancy, no more than Rs. 4,000 is to be expected as the average income of the next ten years, as compared with an expenditure aggregating Rs. 8,700 per annum. With matters in such an unsatisfactory state, it is difficult to understand why operations should be continued at all. The system of tenures in Tanjore seem to be of a complicated nature; and either the Conservator has misunderstood them, or the Government. It seems clear that the system requires to be thoroughly reorganized if anything like satisfactory results are to be expected.

.

In recommending the desirability of adopting a uniform scale of colors for the illustration of agricultural statistics in maps the Statistical Conference of 1883 framed the following resolution on this subject:—

"That as agricultural statistics can often be conveniently represented by means of colored maps, it is desirable that a uniform system of representing percentages by particular colours should be adopted, but that the Conference is not at present able to decide which system is the best. An essential point is, that color cakes, and not colours mixed on a palette, should alone be used, and that the paint boxes should be of the same kind."

The Government of India in the Revenue Department, in consultation with the Surveyor-General, have decided upon a scale which is described as a simple ascending scale, which will be generally employed in showing percentage above zero of rainfall, crops, irrigation, and the like, over different areas. The amount of difference in percentage to be indicated by the different colors in the scale will be left to the discretion of Local Governments and Administrations.

The maps are to be colored by hand, and to facilitate this, the Stationary Department will supply to Local Governments and Administrations, small boxes containing colors in cakes corresponding exactly with the prescribed scale. As soon as a given scale of percentages is adopted, the percentage which each color is to express is to be clearly shown on a label fixed to the inside of every box.

.

FURTHER telegraphic news from Srinugger, dated June 11, regarding the earthquake in Cashmere, states that the Resident has visited Sopor and Baramulla, and is now encamped at the latter place. He found both towns in ruins. At Baramulla, 225 persons were ascertained to have been killed, and 175 at Sopor. The reports from the outlying villages are incomplete; but those received showed great loss of life among the villagers, sheep, and cattle. The ground on both sides of the river from Sopor to Baramulla is scored with cracks, also in the low alluvial hills in the vicinity. The severest shock, since the first, occurred at noon on the 8th, causing heavy landslips. There is a comparatively small number of wounded who were receiving every possible attention from the Maharajah's native doctors, under the superintendence of Dr. Neve, of the Church Missionary Society. The accommodation being very defective at Baramulla, Dr. Leahy, who accompanied the Resident, has arranged to take the worst cases to Srinugger. The Governor and officials are all exerting themselves to the utmost by the distribution, by the Maharajah's orders, of money, clothing, and rice.

The Viceroy has telegraphed to the Maharajah, expressing his regret at the great loss of life and the destruction of property caused by the earthquake, and his sympathy with the sufferers.

.

It may be remembered by some of our readers, that one of the chief subjects of consideration in the relief measures of 1873-74, was the amount of food to be given daily to the people, who were to be fed at the expense of the State. Sir GEORGE CAMPBELL estimated the requirement at $\frac{1}{2}$ of a seer, or 1½ lbs., and after long consideration Sir RICHARD TEMPLE adopted this scale, and urged it upon the Government of India. He wrote:—

In practice it is found that, even to ordinary paupers who did not do any work, local committees had to give $\frac{1}{2}$ of a seer of rice daily, besides one pie for the purchase of salt and condiments. To women in delicate

health, and to persons reduced by previous hunger, a still larger daily dole had to be allowed.

The Secretary of State at the time was the Duke of ARGYLL, and when the question was referred to him, he ordered the adoption of the highest scale proposed, declaring that "It was better to be on the safe side, and to give the people a fraction more than was absolutely essential, rather than a fraction less." Now the Lieutenant-Governor of these Provinces has reduced the relief to less than one-half the scale thus adopted in 1873-74. For the scale proposed by Mr. TAYLOR, and approved by Mr. BEAMES and by the Lieutenant-Governor, is two pice a day for adult men and women, and one pice for children. As the price of common rice is about 12 seers the rupee, this scale of relief will purchase about 12 ounces of raw rice for the adult, and 6 ounces for the child, and we naturally want to know who is responsible for the step. It can hardly have been adopted without reflection, but the fact remains that the relief we are now administering is less than one-half the lowest scale permitted in 1873-74.

.

THE *Straits Times* of the 4th of June has the following regarding the race for tea:—The S. S. *Glenarry*, Captain Alfred Taylor, carrying the first season's teas, arrived alongside Tanjong Pagar wharf, at 9 o'clock on Saturday night, and after taking in a thousand tons of coal, proceeded on her voyage at 4 A. M., on Sunday. The *Glenarry* had, 4,600 tons of tea at £3-10, and left the red buoy at 5 P. M., on the 23rd ultimo, making the passage to this port in 7 days 4 hours. The second steamer with teas was the China Shippers' Mutual Company's steamer *Opack*, which passed Wootong at noon on Sunday, the 24th May, arrived alongside the Borneo Company's wharf at 6 o'clock last Monday morning, (7 days 18 hours) and took in 950 tons of coal in 3 hours, leaving the wharf at 10 A. M. This is believed to be the fastest job of coaling ever executed in Singapore, and reflects great credit upon Mr. Rose, the Company's Superintendent. Messrs. Wheelock and Co's Shanghai freight circular for the mail contains the following about the tea steamers:—From Hankow for London—The steamers *Glenarry*, *Glenfruit*, *Opack*, *Benvenna*, *Pembrokeshire*, *Cyclops*, and *Pathan*, have already proceeded up the river to load New Teas. These will be followed by the *Bothwell Castle*, *Afghan*, *Aberdeen*, *Dentarg*, and either the *Glenfalook* or the *Glenroy*. The *Glenarry* will be the first steamer away, and for her £6 per ton is now being asked, but rates cannot be definitely settled as the *Pathan*, *Afghan*, and *Aberdeen* have not been admitted into the Conference, so there is every probability of great opposition in securing freight, and the consequent resort to low rates. For New Teas, to Russia direct, the *Mussalia*, *Tarantula*, and *Russia*, have already proceeded to Hankow. From Foochow to London, via Suez Canal:—The *Glenaggle*, *Ningchow*, *Danbighshire*, and 'Ben' steamer will load with New Teas at the opening of the season. For New York, via Suez Canal:—The berth is still vacant, but the steamers *Glenavon*, *Glamorganshire*, *Lord of the Isles*, and *Strathleven* have been settled to load with New Teas at Japan and China ports, and another Union Line Steamer will be laid on. The *Glenavon* will proceed to Amoy from Japan, but will take through freight from here at current rates.

.

THE use of gypsum as a manure has often been discussed. In most cases it has been found that its effects on soils was of a negative kind, unless the soil to which it is applied is deficient in the two important elements that make up this substance, viz, lime and sulphur.

Our own views on the subject are borne out by the testimony of a writer in the *North British Agriculturist*, who has evidently studied the subject. He says: Do, or do not, the soils in which it is to be used contain sufficient lime and sulphur for the use of crops? Most of the red soils do contain sufficient of these, unless they have been exhausted by cropping; but it must be borne in mind that all artificial manures, of which superphosphate is the basis, contain gypsum, the result of the application of sulphuric acid to the carbonate of lime found in combination with the phosphate of lime, of which superphosphate is made. It will be manifest, then, to apply gypsum in itself to a soil in which there is either sufficient, naturally or artificially, will be disappointing. If gypsum could be obtained sufficiently cheap, there is no doubt it could be used as a purifier of the

soils, because the sulphur in it, set at liberty, is deadly to all fungoid or other low forms of organic life that produce many of the diseases of farm plants. But where the gypsum is made from the natural rock, it cannot be used in sufficient quantities to economically do this. Where the waste products of manufacturers can be had for carting away, it is an admirable substance for cheaply regenerating worn-out land and freeing it from injurious or destructive insects of all kinds, and also of weeds and rubbish. But it must be used with judgment, for if too much is applied, say, to the stubbles after harvest, and ploughed in, it will not have time to allow the rains to wash away the injurious matters often found with gypsum from the refuse of chemical works, and the succeeding crops might suffer. The gypsum from the natural rock may, however, be freely and safely used on almost all occasions without doing any harm, the only question being: Will it do sufficient good to make it economical? Liebig and other chemists expected great things of it, and thought in its decomposition in the soils it would fix the carbonate of ammonia in the soils, and in the atmosphere and rain water, dews, &c.; and keep the soils dressed with it abundantly supplied with ammonia. No doubt it does this to a certain extent, but though the writer tried it for several years, he came to the conclusion it was only in soils deficient in sulphates and lime that it can be used economically as a manure by itself. It is, however, of very great use as a drier, or as a dilutant to enable concentrated manures to be spread more evenly.

THE following is a Summary of the Weather Reports for March and April 1885, as furnished by the Meteorological Reporter to the Government of India:—With but few local exceptions, March and April were characterised by high atmospheric pressure, and the latter month by an unusual depression of temperature. The pressure remained above the average during the greater part of March, but about the 20th it fell and remained low up to the end of the month. It continued falling, on the whole, till the 7th April, when a slight recovery took place, and amid some oscillations it remained above the normal average till the end of the month. In March, it was most above the normal in Northern India; least so in the Peninsula. In April also, the pressure was, on the whole, above the average except in Assam and Bengal, where it was somewhat below it. On the 27th or 28th March rainy weather set in in the Punjab and on the North-Western Himalaya, and continued at intervals till the 9th April. This rain was accompanied with snow on the hills, and these fallings were repeated at the end of the latter month, when rain again set in in the Punjab, and dust-storms occurred more or less over nearly the whole of Northern India. Except during the rainy periods, dry north-westerly winds prevailed over the greater part of Northern India, sometimes extending as far east as Bengal, and across the Satpuras to the Deccan. On the Malabar Coast, the winds were most frequently from the north-west, sometimes north, and the same in the Northern Deccan. On the East Coast, the winds were steady from south or south-west. In March, the mean temperature differed on the whole but little from the average. In April it was unusually cool over the whole of North Western and Central India, and the greater part of Bombay and especially in the Punjab, Rajputana, Sind, Guzerat and Khandesh, where the mean temperature of the month was from 4° to 8° below the normal. The humidity of the air was slightly in excess in the Punjab and the Central Provinces; in general deficient elsewhere. The rainfall returns show that no rain fell in Cutch, Guzerat, and on the greater part of the Western Coast; and in the Peninsula the rainfall has been very deficient. In March no rain fell in the Konkan or in Guzerat, and less than usual in North-Western India. In April, on the whole, there was an excess in Assam, Cachar, and Northern Bengal, on the one hand, and in the Western Punjab on the other, while there was a general deficiency over the whole of the Peninsula. The heaviest falls took place in Assam, Silchar having 26 inches of rain, and Silbagar about 17½ inches. The greatest local excess during the two months was:—

7½ inches at	Peshawar.
6½ "	Murree.
7 "	Darjeeling.

In April alone Silchar registered about 9 inches above the average.

Mr. J. N. ATKINSON, special Assistant Agent, Godavari, has been devoting a good deal of attention to the introduction and culture of Tassar Silk in the Bhadrachalam taluk. His efforts have not been attended with marked success, but they go to show that much may be expected in time if the matter is taken in hand properly. Mr. Atkinson's report is so interesting, that we give the substance of it below:—

In 1881-82 he found large quantities of tassar silk cocoons lying about the Bhadrachalam jungles and determined to try and establish sericulture as a regular branch of industry in the taluk. He collected some fifty or sixty live cocoons, intending to divide them between the Central Jail, Rajahmundry, and the Rev. Mr. Cain, at Dumagudim, who was anxious to help him. Unfortunately all the cocoons were by mistake sent to the Central Jail. The then Superintendent, Major Plocke, took a great interest in sericulture and succeeded in getting a small crop of eggs, his great difficulty was in getting connection established between the males and females. But no formal report by him on the result of his efforts appears to have been made, and that since he left the jail the attempt to carry on sericulture has been abandoned.

The Rev. Mr. Cain was also anxious to start sericulture at Dumagudim. At the same time Mr. Atkinson used his utmost endeavours to interest the Koyls and the taluk officials in his experiment. But neither Mr. Cain nor he could overcome the hopeless apathy of the people, and he was obliged to make a fresh departure.

Knowing that at Mangapet, in the Nizam's dominions, a village on the Godavari some distance above Dumagudim, sericulture was carried on by a large number of people, who live solely by it, and must therefore make a profit out of it, he determined, if possible, to import one or two professional sericulturists, and to try and persuade them to settle in the Bhadrachalam taluk permanently. He succeeded in getting two men to come from Mangapet to Bhadrachalam, and promised them that until they were able to make a profit by their trade in their new home, their wages at Rupees 6 each per month, would be paid.

The two men came in June of last year, and after examining the jungles in the neighbourhood of Bhadrachalam settled at Cheruballi, near the Bustar frontier, and commenced operations by the end of June. The first crop of silk was said to be good, the second was in great measure lost owing to heavy rain, and the third was a fair crop.

Towards the close of last year when the third crop of silk was almost all gathered, it became apparent that the two cultivators had no intention of settling in the Bhadrachalam taluk. They made the usual excuses that it was not their native country, that they could not live there, and so forth. And as no good was likely to come by forcing the men to stay, they were on the 15th January last, after the whole of the third crop had been gathered and stored in safety, allowed to go. The men were Koyls, and he was disappointed that he could not persuade them to stay. Mr. Atkinson was still more disappointed that not a single man in the Bhadrachalam taluk, Koyl or otherwise, evinced a desire to adopt the new means of livelihood presented to them. As a matter of fact, he believed the real objection to learning or carrying on the trade was an absurd superstition that prevails as to the manner of life that must be followed by the sericulturists during certain portions of the process of cultivation, involving abstinence from sexual intercourse and other hardships.

The immediate results of the experiment were as encouraging as could be hoped. From the thirty cocoons which formed the breeding stock to commence with, he got about 15,200 cocoons, of which, roughly, two-thirds are in fair order and imperforated, the remainder not having been boiled early enough, or properly, being perforated. These have been forwarded to Messrs. Simson Brothers, who have undertaken to consign them to their agents in Europe and ascertain the value of the crop.

The sum expended on this experiment, was Rs. 93-14-2.

The following important observation we quote in Mr. Atkinson's own words:—

"That the country itself is suited for silk culture is proved by the large quantities of wild tassar cocoons which may be found lying about the jungles. Now, if sericulture can be carried on at a profit in Mangapet, I cannot see any reason why it should not be equally easy to do the same in the Bhadrachalam taluk? Indeed, it ought to be easier, seeing that Bhadrachalam lies so much nearer the great central marts of Rajahmundry and

Cocanada, than Mangapet is to any large town at all. It is certain, too, that any private person carrying on the trade could do so cheaper than I did. It might be combined with an agricultural industry—nay, it might easily be carried on by women and children without interfering with other business. Then again it is not a mere question of pecuniary profit. But I think Government should not lose sight of the immense benefit to be derived from the provision of a new means of livelihood in a country where agriculture is almost the only calling, and yet where the agricultural produce of the country is altogether insufficient for the mere sustenance of the inhabitants."

The introduction of a new industry, such as silk cultivation and silk weaving, will help very much to civilize and raise the people. And in the wild inaccessible tracts like the Bhadrachalam taluk, it is assuredly a legitimate function of Government to use every means of spreading civilization.

Further efforts might be made on behalf of Government to acclimatize this new industry in the taluk.

The Madras Board of Revenue made the following paradoxical remark on Mr. Atkinson's report:—"Perhaps the abundance of the tassar cocoon in the jungles, is a bar to the introduction of sericulture on an extended scale in the Bhadrachalam taluk."

But the Madras Government took a different view of the question, and remarked, that "the Bhadrachalam jungles would appear to be an excellent field for experiments."

DERA ISMAIL KHAN SETTLEMENT REPORT.

THE settlement of the Dera Ismail Khan District, which occupies an area of 9,296 square miles, being the largest comprised in any district in the Punjab, was first commenced by the Settlement officer, Mr. St. G. Tucker, in 1872, and completed in 1879, at a nett cost to Government of Rs. 4,04,702.

The Government of India in the Foreign Department, to whom the report was submitted, consider that the money has been well spent.

It is stated that only one-seventh of the entire area is cultivated, and that the district stands thirteenth among the districts of the Province, in point of extent of cultivation. Two-fifths of the area are situated trans-Indus, and the remaining three-fifths lie cis-Indus. It is divided into three strips of country running north and south, viz., Daman, or flat level tracts, Trans-Indus; Kuchi, or low lands, situated on both sides of the Indus, and subject to its floods, and the Thal, or sandy wastes, which bounds the districts to the east. The cultivated area amounts to 806,000 acres, of which rather more than half is unirrigated. The average rain-fall is less than nine inches. The area irrigated by river floods is stated to be 196,000 acres; by wells, 93,000 acres; and by mountain torrents, 81,000 acres. Of the cultivated area, 326,000 acres are held by Jats; 245,000 acres by Pathans, and 134,000 acres by Beluchis. The principal crops are wheat (319,000 acres), bajra (263,000 acres), with sarson, (mustard), cotton, jowar and ussum. The proportion of the area cultivated by tenants is comparatively large, being 320,000 acres, or nearly one third of the whole. The area held by occupancy tenants, who number 9,668, is 131,000 acres. The population, according to the last census, was 411,649, giving a rate of 47 per square mile of the total area, and 351 per square mile of the cultivated area. The number of Hindoos is insignificant, being only 54,000.

Although the Settlement officer has not given any separate account of the present prosperity of the district, as compared to former years, yet it appears that in one Tahsil the number of wells has increased from 645 to 726; and the cultivated area in another more than double that of 1854 and 1861; and the selling price of lands has also increased. Generally speaking, the people are said to be well-to-do, the only unsatisfactory feature being the amount of mortgage debt existing in it. But this subject, we find, is receiving the separate consideration of the Punjab Government.

The system of land tenures is described as exceedingly complicated, and possessing features which are markedly different from those found in any other part of the Punjab. A full account of these is given by the settlement officer, and need not be described here in detail, suffice it to say that the people

are divided into superior and inferior proprietors. The former also hold land as inferior proprietors, and cultivate them on the same tenure as any other class. The superior proprietorship is usually held undivided under the *zomindari* form of tenure. It consists of a payment of Rs. 1-12-0 per cent on the revenue, together with certain rights in the common land which is generally considered the property of the superior proprietors, subject to certain privileges enjoyed by other members of the community. The real nature of the various complications of tenure was in many cases not understood before the present settlement, and the explanations now given of them by the settlement officer ought to prove very useful in future in deciding cases regarding rights in land and water.

The Settlement officer has given an interesting account of the independent tribes beyond the frontier, and of the Powindah carriers. These, it may be remembered, joined in the Mahsud Waziri attack on Tonk, in January 1879, of which much has been written already.

With regard to assessment, it has been decided to apply one that is partly fixed and partly fluctuating, and the rates at which these have been proposed, are considered light. The total assessment demand is given at Rs. 83,000; of this sum 22,000 represents the fixed demand, and Rs. 61,000 the fluctuating demand. The actual average collection's during the years, since settlement, have been Rs. 12,000 and Rs. 8,200; but this decrease was due to the seasons of 1876-77 having been unfavourable.

The total Government area in *rukhs* is 1,261 square miles. Grazing land has been assessed lightly, but over this land the proprietors have full control, as regards the grazing of kine, sheep and goats.

The assessment on date groves has been increased from Rs. 1,050 to Rs. 6,104, which gives an average of one anna per fruit bearing tree.

The entire revenue according to the former assessment was estimated at Rs. 4,74,045, while under the new assessment, it is put down at Rs. 5,61,795, being an increase of Rs. 87,750, or 18 per cent. But this increase cannot be regarded as actual. It seems that Mr. Tucker under-estimated the amount of the grain collection by Rs. 16,743, and the *rahi* and *trai* receipts by Rs. 2,956, while he overestimated the assessment of the Daman lands by Rs. 10,202, and of the kachi by Rs. 26,151; so that taking the former the under-estimated sum, Rs. 19,693, and the over-estimated sum, Rs. 37,143, subtracting the former from the latter, the increase of revenue obtained by the new assessment must be reduced by Rs. 17,450, which will leave the actual increase in the assessment at Rs. 60,300, or about 12½ per cent. Of this sum, it appears that nearly Rs. 20,000 have been devoted to *inams*, to *zaildars* and other leading men, and Rs. 12,000 have been granted to *jagirdars* in compensation for losses caused by the abolition of their collections in kind; while Rs. 22,000 have been alienated in providing *jagirs* for two Nawabs. Therefore the actual increase of revenue amounts in round numbers to a little over Rs. 6,000. No alterations have been made in the dates for the payment of the instalments of revenue.

The amount of revenue enjoyed by private persons and Government servants in 1878, was Rs. 1,91,293. The greater portion of the *jagirs* are enjoyed by the Multani Pathans of Dera Ismail Khan. The settlement officer recommended that the settlement be confirmed for a period of 30 years, but in view of the fact that the fluctuating assessments are undeniably light, that the district may possibly be connected by railway with the rest of the province before long, and that it is under contemplation to organise a series of inundation canals from the Indus, from Mozuffurgurh up to Kalabagh, it was not considered desirable to sanction the settlement for the period of 30 years; and sanction has, therefore, been accorded for 20 years, with effect from the date when the new assessment of the district was completely introduced.

On the whole, it appears that Mr. Tucker had a very difficult and complicated task to perform, which he has carried out to the entire satisfaction of the Lieutenant-Governor of the Punjab. We agree with Sir Charles Aitchison in regretting that the great length of the report was not somewhat curtailed. It is seldom borne in mind that the only excuse for a lengthy

official report is the interesting matter which it may chance to contain; and even the absence of interest may be compensated for to some degree by the style of writing the report. It is not our wish to "pick-holes" in Mr. Tucker's very exhaustive report, but we could not help noticing some passages that might have been better written. For instance at page 7, para 14, the following passage occurs:—"The irrigating channels are full, and every one tills his *bunds* as fast as he can, and then closes their mouths." Another at page 8, para. 16:—"The ground is generally more or less overgrown with different sorts of *tanq*, which is much grazed by camels." The word "grazed," is peculiarly used. At page 9, para. 18, the following vague passage occurs:—"Here and there, as in the *Shera iliqua*, where irrigation is unusually certain, and the country is all cultivated, the villages lie close together in the middle of their fields." There is no noun to which the pronoun "their" could apply. We have just selected these passages at random to show that there is room for improvement. Mr. Tucker has shewn his ability in settling and preparing a record of the multifarious rights in the Dohra Ismail Khan District, and something better than this class of English might have been expected from him.

INDIAN TRADE WITH AUSTRALIA.

INDIAN trade with Australia has hitherto not been developed to any appreciable extent. Efforts have, from time to time, been made to open up a trade for certain kinds of Indian produce in the Australian markets, and *vice versa*, but with indifferent success. In 1883, this question appears to have been taken up somewhat energetically, but it was found that, in the trade with Australia, there had always been a very large excess of exports to Australia over imports from that colony, and that the increase in exports, however satisfactory, was not likely to assist in leading to the increase in direct shipping communication with Australia, unless some return trade was thoroughly established. It was pretty well known that Australia did not send much to India, except in the shape of horses and metals; and it was considered doubtful whether there was anything else the Colony could afford to send to India in any quantity, except perhaps timber and *ghee*. The high price of labour in Australia precluded competition in India in any manufactured article, or any production in which human labour was an important element. Wool was not yet in demand, while frozen meat and preserved fruits, it was thought, would only meet a small demand from the European population, or perhaps a small section of the native community. Timber, on the other hand, might be taken for public works, but the whole native population was a customer for *ghee*. The quantity of this article consumed in British India, exclusive of the Native States, has been estimated at considerably over five million cwt. per annum, the value of which may be set down at 14 millions sterling. Moreover, the price of *ghee* is gradually rising, owing to the continuous decrease of grazing land, and the greater profits derived from the cultivation of produce. Therefore, the import of *ghee* from Australia, if once introduced, would meet a constantly rising market, and become more and more profitable, and it was considered desirable to open, if possible, an extensive trade in this commodity.

With this object in view, the Government of India, in April 1883, decided on attempting the manufacture of *ghee* in South Australia, and asked the Colonial Government whether the experiment could be undertaken in the neighbourhood of Port Darwin. At the same time the desirability of importing buffalo-cows into the northern tracts of Australia was suggested as a matter worthy the consideration of the colonial authorities; and as an incentive, an offer was made to present the Government of South Australia with three or four buffalo-cows, and one bull of good breed for the purposes of the experiment.

The offer was accepted, and in August 1883, three *ghee*-makers and one bull, and three cow-buffaloes left Calcutta for Port Darwin, where they arrived in September. The bull had died, and two more bulls were sent in his place in charge of two *ghee*-makers in February. During the time that the men were in the colony, they were engaged solely in the manufacture of *ghee*. The result of the experiment showed that the climate is suitable

for buffaloes, and the stock were well when the last report was received. The cows had also given birth to healthy calves.

The *ghee* manufactured was excellent, and obtained a gold medal at the Calcutta Exhibition, where it was highly reported upon by experts and the military authorities. Mr. H. J. Scott, Commissioner for South Australia at the Exhibition, reported thus on the samples exhibited:—

"Near the close of the Exhibition, I received a case from the Resident at the Northern Territory, containing twelve jars of *ghee*, manufactured by Hindus, from buffaloes presented by the Government of India. As it was long past the allotted time for receiving exhibits, I made formal application, and received permission from the Executive Committee to enter it for competition. It being a question of caste prejudice whether the natives would eat it, I forwarded, through Lieutenant-Colonel Cologan, six jars to the Colonel Commanding the native troops in Port William, and have since received and handed to the Minister controlling the Northern Territory an authoritative opinion as to its quality, in which it is stated the natives liked it very well; that that it was refined too much, or, as they expressed it, "too good" for the market. The bazaar price varies from one to one and-a-half rupee per seer—that is 10s. to 1s. 3d. per lb., according to season. I gave one jar to Dr. George Watt, Economic Museum; one to the Baboo in charge, and others to the Government Analyst, for examination. They each presented separate reports, giving it a high position and awarding the first order of merit, gold medal to the Government of South Australia. The teeming population of India use *ghee* for every-day use with their food; their daily wants are enormous. Something like 300,000 tons of this clarified butter are annually consumed by the natives, and it is to this product we must look to open up a reciprocal trade when our horses are shipped from Port Darwin."

Owing, however, to the small scale on which the experiment was tried, the cost of the *ghee* was necessarily high, and as observed by the Colonial Government, it is impossible from the data at present available, to say whether a trade in *ghee* can profitably be established with Australia.

It may, perhaps, be explained here that, at the time of the Melbourne Exhibition (1883-84), a note was circulated in Australia by Mr. E. C. Buck, at that time Director of Agriculture and Commerce in the North-Western Provinces and Oudh, and appointed President of the Committee for India at the Melbourne Exhibition, which had for its object the encouragement of *ghee* manufacture in Australia, and explained at length the method of manufacturing this article in India. It was insisted that, for the exported article to take with the natives, it was absolutely necessary to imitate the Indian article as closely as it was possible to do so. In this connection, it may be noted that the verdict pronounced upon the *ghee* exhibited at the Calcutta Exhibition that it was "too good," may be taken as an indication of the native estimate as to the quality of the *ghee* that is likely to meet with a ready market in India. The verdict bears out Mr. Buck's opinion that, for the Australian *ghee* to succeed in India, no attempt should be made to deviate in any way—even for presumed improvement—from the appearance of the manufactured article as brought into the market by natives themselves. We are not in a position to say whether any further attempts have been made in the direction of exporting Indian buffaloes to South Australia since the last shipment was made; but certain it is that, if there is to be any reciprocity in trade between India and Australia, to any large extent, our economists must hit off something outside of *ghee*, the manufacture of which by the Australians has not met with that measure of success which was anticipated from it.

Miscellaneous Items.

THE population of the North-Western Provinces and Oudh was increased in April by the birth of 136,854 children.

WE understand that Government contemplate doing away with appointments of Forest Settlement officers, in view to effecting a saving to meet the war-preparation expenses.

WE learn that two members of the Bengal Civil Service intend shortly taking two years' furlough each, in order to pass that time at Cirencester, as out-students of the Royal College of Agriculture.

Good rains fell along the Malabar Coast, between Goa and Cochin, on Sunday, last week, averaging about two inches all down the line, and a little has spread over the Central Provinces, but Bombay and Bengal are as yet without rain.

During the month of April the total deaths from all causes were 86,169 in the United Provinces, N.-W.-P. and Oudh, compared with 82,841 in the previous month, and 150,048 in April of last year. As usual, fevers of kinds are responsible for the majority of the month's mortality, 74,186 having succumbed to such causes.

The rules framed under the Punjab Municipal Act of 1884, for the appointment of Municipal Committees in the Province, have received the final sanction of the Lieutenant-Governor. They differ in the slightest degree from the draft rules published in March last; very few complications having been added, and nothing in the way of simplification.

On reconsideration of the subject, the Government of Madras is of opinion that it would be better to forego all duty on salt used for curing fish, having regard to the advantages to the public which will accrue therefrom. The present system of supply at cost price will be continued, and it will be the object of the department to suggest measures for extending the benefits of the system.

It has been decided that the existing gauge of the Bellary section, of the Madras Railway, shall be undisturbed, as Sir Frederick Roberts, who has consented to the removal of the Arsenal from Trimulgherry to Bellary, as suggested by the Director-General of Ordnance and approved by Government, considers that, consequently, it is of paramount importance that the gauge of the line from Madras to Bellary should be unbroken.

The French local Government has succeeded in affording sufficient relief to the ryots of Pondicherry and Karikal, who suffered from the late inundations, to enable them to carry on the cultivation of their lands without the loss of any crop. The loans are repayable in five years by instalments, plus a small charge for interest; but the Director of the Interior has full powers to grant extension of time, and also to make remissions in certain cases.

From the Railway Administration Report we see that the works on the Cawnpore-Kalpi line are well in hand, and, with the exception of the bridge over the Jumna, are expected to be completed about January next. The bridge at Kalpi will consist of ten spans, each of 250 feet. Seven out of the ten wells have been sunk to depths varying from 50 feet below low-water level, and if funds are available the bridge may possibly be finished by the middle of 1887.

As a step towards improving the live stock of the country, by the influence of example, the Director of Revenue Settlement and Agriculture recently proposed to encourage land-owners and Mo-fussil stock traders, by substituting presentations of live and dead stock for the money prizes which it is now the custom to distribute at Agricultural Exhibitions. These proposals had the concurrence of the Board of Revenue, and have now received the entire approval of the Government.

Two French steamers have sailed, from Pondicherry for Marseilles direct, during the last week: *The General*, Captain Escarra, with 15,000 bags, and the *Panama*, Captain Favard, with 20,000 bags of ground-nuts. There is no vessel loading at present, but four steamers have been chartered to load during the next four weeks; these will take about 150,000 bags, which will clear off the greater part of present stocks, and as arrivals continue to decrease, the season's business may be expected to close some time next month. The total figures are expected to fully reach the original estimate of half a million bags, which is 250,000 bags less than last year. Prices have been fluctuating, and a few days ago Rs. 31 were touched—quotations were Rs. 20 to Rs. 20-8, per French Candy.

Mr. A. M. MARKHAM supplies the following to the Allahabad paper:—"Sir,—As I have recently seen it tried with marked success, I think it right to call attention to the fact that the root of *Asclepias speciosa* affords almost instantaneous relief from the pain caused by the sting of a scorpion. The plant is very common everywhere, and is one of those whose clinging burrs are such a nuisance on one's legs when out shooting. It is called *chirchira* by the natives of these provinces. The root macerated in water is applied to the part stung, and a small quantity is drunk. If this be done quickly, there is absolutely no pain 15 or 20 hours or so after the sting, instead of the 12 to 24 hours of intense suffering which follow an untreated sting. Three cases occurred recently in my camp, in which the sufferers, thanks to *chirchira* and the presence of a khittmutgar who knew how to apply it, were going about their work within an hour in each case, feeling nothing more than a numbness in the part stung. I am aware that this is no new remedy, but its value cannot be too widely known."

One more sign of the times was the meeting again last week of the Executive Committee of the Bombay Exhibition. Twelve months is none too long a period for completing the necessary preparations, if the undertaking is to be made worthy of India and Bombay enterprise; but if an interval of two months were always to elapse between meetings, the year would slip by, long before arrangements could be perfected. The committee were, however, not to blame. Russia is the culprit. With war rumours thickening in the air, it would have been ridiculous to push on an enterprise which war would have rendered fruitless. Now, however, that the political atmosphere smells less of gunpowder, the Committee promise a renewal of vigorous action. At last week's meeting a considerable amount of solid business was disposed of. The Government offer of the parade-ground as a site was gratefully accepted, and the prayer of Mr. Nansubhai Jeejeebhoy for the admission of press reporters to committee meetings was ruthlessly rejected. A cautious reply was returned to Government in the matter of purchasing the second-hand Indian exhibits from London at cost-price; and the constitution of sub-committees and other departmental arrangements proceeded with. The date of the next meeting was fixed for such time as the Chairman thought matters were "ripe" for it, which ought not to be long in this sunny weather. The rains, too, are approaching, when it is not easy for the most energetic committee to prevent the grass growing under their feet.

REVENUE DEPARTMENT.

FAMINE.

DARJEELING, THE 11TH JUNE, 1885,

RESOLUTION.

READ—

A letter, with enclosures, from the Commissioner of the Presidency Division, dated the 26th May 1885, reporting the result of local enquires made by the Collector of Moorshedabad as to the condition of the people in Khargram, in the Moorshedabad district.

On the 18th of May the Lieutenant Governor received a telegram purporting to emanate from the Special Reporter of the *Bangabasi* newspaper, in which it was stated that 31 deaths had occurred from starvation in the village of Khargram, in the district of Moorshedabad, and that, if help was not speedily given, one-fourth of the population of the place would die in a fortnight. This statement was reproduced in the *Scotsman* newspaper of the 20th idem, and was made the text of a hostile criticism. The information took the Lieutenant-Governor by surprise; for, although the condition of certain distressed tracts in the Burdwan Division had been the subject of frequent correspondence, no report, official or otherwise, had reached him to suggest the likelihood of any mortality through want of food in Moorshedabad.

2. On the date of the receipt of the information, the Commissioner of the Division and the Collector of the District were directed to institute the closest enquiry into the facts. The results of that enquiry are now published for general information as an appendix to this Resolution. A house-to-house investigation, supported by an exhaustive record of evidence, shows not only that not a single death from starvation has occurred in Khargram, but that owing to the dryness of the season and the consequent decrease of malarious fever, the death-rate of the place has been considerably less than usual. The papers further show the great improbability that any deaths from starvation should occur there, as the local authorities, in accordance with the arrangements indicated by the Lieutenant-Governor, in his Resolution of the 18th November last, were fully alive to the necessity of affording relief to all who were in need of it. The condition of the tract in which Khargram is situated, and which has suffered to some extent from a succession of bad harvests, has been carefully watched by the district officers. The locality was visited in December by the late Collector, Mr. Farrer. It was again visited in February, by the present Collector, Mr. Anderstun. No need for charitable relief has been apparent, and the applicants for employment on relief works, which are available, are few. But the enquiries of the Collector, and the information supplied by local residents and officials, go further than merely proving that the communication made to the Lieutenant-Governor, by the correspondent of the *Bangabasi*, was unfounded. They place beyond doubt the fact that the correspondent referred to, made no effort whatever to verify the intelligence he thought fit to communicate to Government, while they furnish strong reasons for believing that he had been deceived by interested parties, who were only anxious that Government money should be spent among them.

3. In connection with the distress which unhappily prevails in certain localities in Central Bengal. Sir Rivers Thompson has always welcomed, and has been ready to act upon, authentic information conveyed to him by those having local experience. On more than one occasion he has acknowledged the assistance which Government has received from independent quarters, in dealing with the pressure from which the people are suffering. It must, however, be obvious that when false reports, which when traced to their origin, are found to emanate from unworthy motives, are made the means of occupying the time of public officers, in harassing and useless investigations, the public interests must suffer. A responsibility thus rests upon those who are forward to give currency to fictitious and unverified reports.

By order of the Lieutenant-Governor of Bengal,

A. P. MACDONNELL,
Secretary to the Government of Bengal.

CINCHONA GROWING IN JAVA.

THE officers in charge of Government plantations in the Dutch East Indies do not wait until the middle of 1885 before issuing their reports for 1883, as does the Director of Kow, nor do they ever let a whole year go by, as in the case of most of our Colonial Botanical establishments, but regularly every quarter full particulars of the work in progress are sent to the Executive Government, and at once published in the local papers. Thus we have now before us the report of Mr. Van Romunde, Director of the Government Cinchona enterprises, for the quarter ending December 31st last, and we quote below some passages which will be of interest to growers in our own tropical possessions. The gathering of bark was, so far as the weather permitted, carried on uninterruptedly. As in the previous quarter, so also in this, pretty large quantities of Ledgeriana alivers were gathered. Important experiments were made with the scraping of Ledgeriana and officinalis, which deserve mention. As has already been noticed, the middle and the end of the east monsoon are the best periods for showing off the bark. In order to dispense with covering, the trees were shaved over only half their circumference, so that, for example, one year the south half, the next the north half is subjected to the operation. The question was raised, however, whether the trees might not yield two crops of bark in one year, without covering, by means of scraping. The experiment was made on a large scale, and the result has so far fully answered expectations under the following conditions:— (1) That a thorough working of the soil accompany the repeated shaving; (2) that between the two croppings a period of at least 2½ months elapse. If both conditions be not carried out, the trees suffer especially after the second operation, to such an extent that they soon assume a sickly appearance. The question has now to be solved, whether the trees will be able to bear the repeated operation, as well as whether the composition of the renewed bark warrants the above-mentioned method of harvesting. The graft plantations of known, analysed trees at Tirtasari ought, during 1885, to yield the necessary material for chemical investigations. The crop of 1884 comprised about 350,000 Amst. pound. Of this by December 31st, 314,387lb. had been despatched to Batavia, whilst 2,263lb. were reserved for the local military medical service. On 15th October the second half of the product of the crop of 1883 was sold by public auction at Amsterdam. The prices obtained were considerably less than those fetched at the sale of 19th July. The highest price was paid for a lot of Ledgeriana alivers, which fetched as high as /2 19 per half kilogram. The lowest price was given for dust of C. Josephiana which bark realized only /0 05 to /0 32 per half kilo. As the harvesting of this most inferior bark no longer pays cost of packing and dispatch, the product of young branches and twigs will in future not be gathered. Good prices were paid for Officinalis barks. These varied from /1 76 per half kilo, for root bark, to /0 85 for dust. The nett result of the sale was about /145,000 with an average price of /69 per half kilo. A beginning was made in November with the planting out, which work is, so far as the weather permits, being carried on uninterruptedly. The plentiful rains, after the severe drought in the last monsoon, had a favourable influence on the growth of the plantations, whilst the plants in the nurseries also developed vigorously, and will yield a good supply for planting in the first quarter of 1885. Shortly after the setting in of the rains the *Helopeltis Antonii* again appeared in full force, especially at Tjinjirouan and Tirtasari. By a timely catching and killing of the insects the damage done was very small. The sale of Cinchona seed at three auctions held during the quarter brought in /4,770, whilst at two sales of grafts 380 of these were sold for /3,600. By Government order No. 40.

of 29th December, 1884, it was resolved that in future the Ledgeriana grafts and Cinchona need not be required for the Government enterprise, but should be sold by public auction without limit.—*Planters' Gazette. (English Paper.)*

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The Ordinary General Meeting was held on Tuesday, the 2nd June, 1885. (Postponed from Wednesday, 26th May.)

COMMUNICATIONS.

MR. W. STIEFELHAGEN, of Boorancherra, Cachar, states he has lately discovered black pepper (*Piper Nigrum*) growing wild in the jungles, and offers to send plants, and later on, seeds, to the Society. The offer accepted with thanks.

From Mr. W. Claxton Peppe, Birdpore, Gorruckpore, who writes as follows:—"Last year, when in England, I searched for a small Rice-Husking Mill, but could find none but what required heavy machinery to drive it." He goes on to ask for further information regarding the rice husker, drawings of which are given in the Society's Journal for 1884, which was duly supplied.

From Mr. Manuol, Rangoon, asking for a small quantity of silkworm seed of the best Bengal variety of silkworm, he says: "I am desirous of attempting a cross between the Bengal and Native Burmah kinds, with a view to securing a better breed than we have at present. Our variety, the *Bombyx Arracanensis*, is a hardy poly-voltine, running through its cycle in from 40 to 45 days, but the silk is inferior and the cocoon is spotted," according to Wardle this variety was introduced from China, so there is every prospect of the experiment being attended with success. Mr. Manuol has been put into communication with Mr. Cleghorn, a member, who is devoting much attention to the subject of Indian Silk.

Mr. J. Anderson, U.S., writes from Berhampore in reference to silk. "I enclose a slip sent me by a silk planter of this district enquiring about the silkworm tree, and offering to take charge of any he could get." The following is the extract:—

"Those interested in sericulture in India may be interested in the description of a tree found in Szehuen, which is used extensively as a source of food for silkworms. In the western parts of the province, Mr. Hosie, who went through Szehuen, in June and July of last year, reports a new tree which he thus describes:—

It stands from 10 to 15 feet in height, and resembles an overgrown tea tree. Its leaves, which spring alternate from the branches, are of a dark-green colour, smooth, ovate, acuminate, and not serrated. It is very extensively grown, and its leaves are used to feed the silkworm in their infancy. The local name is the *tsa* (also in the north) *yeh* tree. It is apparently a species of thorn. The peasantry insist that unless the young silkworms are fed with the chopped leaves of this tree, the output of silk will be less and of an inferior quality.

"It would be well if the new Bengal Agricultural Department interested itself to procure specimens or cuttings of the tree."

Dr. Macgowan, Corresponding Member of the Society in China, has been addressed on the subject.

From Captain Vyse, Station Staff Officer, Shajehanpore, asking for information and advice on the culture and treatment of Mango trees. He has been advised of the method lately found very satisfactory in England.

Messrs. Lahiri, Chatterjee & Co., of Calcutta, forwarding a sample of cotton which they say is disputed, and asking the Society's opinion as to the district in which it was produced. It was referred to Mr. M.V. Higgins, of Messrs. Haworth & Co., who kindly gave a Report. He identifies it as *Assam*, and considers it would command a good price in the Calcutta Market.

Bauhinia Vahlia.—From Captain Pogson, enclosing a letter to him from Mr. Smythies, Deputy Conservator of Forests, Dehra Doon, and forwarding a parcel of *Bauhinia Vahlia* seeds; Mr. Smythies says:—"This is one of the commonest climbers in India, and has a wide range, I should be glad if the natives would eat the seeds, pluck all the leaves, and cut down all the stems of this climber in our forests. We wage war against it, and have already cleared a considerable tract in Ramgarh of this weed. The stem is sometimes five feet in girth, and the leaves range up to 18 inches diameter.

We annually grant a large sum for the destruction of this climber and eventually shall exterminate it; but it will be a work of time. In the open forests, I am afraid, it will remain for ever."

Captain Pogson remarks that it is a pity such quantities of this superior fibre should not be utilized.

LEMONS IN INDIA.

Dr. Bonavia, of Etawah, writes in reference to this subject, as follows:—

"I wish to bring to the notice of your Society a most important tree, viz., the *Malta lemon tree*, which I imported from the Mediterranean many years ago, for the Horticultural Garden of Lucknow. I lately sent four plants from here to Dr. King to ascertain how it would stand the moist climate of Bengal. I wish your Society would take it up also, and make some experiments to ascertain its value in that climate. The facility with which it can be propagated is simply marvellous. It stands the climate here with the least case, and I believe would do everywhere in India, where oranges and lemons can be grown, Sylhet, Nagpore, Delhi, Nepal Valley, Kangra, &c. If we could obtain citric acid easily in India and cheaply, there is no reason why *Ultrate of Iron and Quinine* could not be manufactured. It is the most important tonic to Quinine, and would be invaluable for picking up the strength of people recovering from fever. The commercial products of the lemon tree are many. Could you kindly help me in obtaining the statistics of imports

into India, through Calcutta, Bombay, and Madras, of the following commercial products of the lemon and the orange, viz.—

1. Citrate of iron and quinine.
2. Citrate of iron and ammonia; there are other citrate drugs, but I think these are the most important, but some of the Calcutta chemists may mention others.
3. Citric acid for pharmaceutical purposes, and for aerated waters, (tartaric and sulphuric acids are often used now for lemonades, because citric acid is dearer.)
4. Essential oil of lemon (of the rind) used in pharmacy, confectionery, and for flavoring lemonades. These lemonades are now so very "popular," as most of the army, railway employes, &c., &c., are becoming teetotalers.
5. Lemon drops and other confectionery where this essential oil and citric acid are used.
6. Candied lemon and orange peel.
7. Oil of neroli (essential oil of flowers of Citrus Bigaradia, and others. The C. Bigaradia, or Seville orange, grows here just as well) for confectionery, perfumery, pharmacy, &c.
8. *Petit grain* for scenting soaps and perfumery. This is the essential oil of the leaves of C. Bigaradia.
9. *Marmalade*.—Of this, there ought to be a great consumption in India in this.

I have been experimenting with the *citrus lemonum vulgaris*, of Rio, for nearly 25 years, and the more I see of it, the more highly I think of it as an industrial plant for India.

The statistics of the imports into Calcutta are not readily obtainable, and as the Custom House does not keep the details, it would seem hopeless to try to collect them from the many imports of articles in question, but such figures as can be obtained will be furnished to Dr. Bonavia.

RICHARD BLECHYNDEN, JUNIOR,
Deputy Secretary.

THE COMPOSITION OF MILK.

(By PROFESSOR SHELTON.)

THE production of milk in the mammary glands of female animals of the order mammalia, is at once one of the most involved, and curious, and valuable processes in the domain of organic nature. The conversion of grass, and hay, and grain, and roots, and such-like raw materials, into an exquisite fluid, which is extremely valuable to mankind, deserves to be universally understood and appreciated. That the milk from which we make cheese and butter comes from cows we all know, and we are equally familiar with the fact that it is primarily derived from the food which the cows eat; the *modus operandi*, however, is not generally apprehended, and it is worth while to make some inquiry into it, not for curiosity's sake only, but in order to promote greater respect for the cow as a servant of man, and greater care in the system under which she is managed. Charles Dickens said that if mankind were to return to the worship of animals, the cow would become the chief divinity; and in this he paid a noble compliment, not in the least undeserved, to the most valuable of domesticated quadrupeds.

The most advanced researches into the mammary glands of the cow have revealed a wonderful ramification of ligaments and tissues which, interlacing each other, support the udder in position, and admit of its distention and contraction. Within this structure blood-vessels pass to and fro, and milk-ducts, cavities, glandules, lobules, and vesicles are distributed, forming together the organic substance of the udder. Here it is that the valuable constituents of milk are elaborated and blended. Within the cells and vesicles the fat of the animal, in itself comparatively colourless and tasteless, is thrown off by a process which may be termed 'budding,' and is at the same time transformed into the much more pleasing fat known as butter, in the form of globules whose dimensions are microscopical. These globules, or buds, or fatty pollen, as we may term them, when perfected, drop off into the cavities, in which they come in contact with, and are taken charge of, so to speak, by the water therein, which also contains casein and albumen that have transuded from the tissues of the animal's body; and they are carried along through duct after duct into the acini, or milk-cisterns, and the emulsion is finally extracted from the teats.

When milk is placed under a powerful microscope the cream-globules in it, like the lobules and vesicles in which they are formed, are seen to be irregular in size and form, some spherical, others oval; their form, however, is always rounded, having a rounded and not an angular exterior. This external evenness is due to the semi-liquid contents of the globules—I say 'contents,' because it is not yet fully demonstrated whether or not they are enclosed in an envelope of any kind, albuminous or caseous, or otherwise, or by serum condensed by attraction. The subtle process in nature's chemistry, by means of which the ordinary fat of the animal is changed into the peculiar combination of fats with which we are familiar as butter, and the means by which are obtained the no less singular odour and flavour of butter, both of which differ so much from anything else we know, are, and probably will remain, among the occult mysteries of nature. But it is evident enough that the milk glands are the seat of a wondrous activity to supply

the countless myriads of infinitesimal cream-globules which are found in milk; and they are the no less wonderful theatre of mysterious chemical processes which produce the delicate flavour, aroma, and colour of butter. Countless, indeed, are the cream-globules in milk, for Fleischmann has calculated that a pound of milk, containing 4 per cent of butter, contains about 40,000 millions of them; and yet in fresh milk no two of them, as a rule, are so near together but that a third may pass between them.

It follows, then, that as these cream globules have actually been part and parcel of the system of the cow, they will consequently always harmonise with the nature, character, and condition of the animal by whom they are produced; and as cows differ considerably in the nature of their organisation, so will there be differences in the quality of the milk they yield. Cream-globules are composed of fatty matter, and fat is lighter than milk; hence they may be regarded as tiny balloons, which seek the position to which their specific gravity entitles them, and hence, too, the ascent of cream to the surface of milk which is at rest. Some of them, however, are so tiny, that the fat in them is too minute to float them to the surface, and these remain *in situ*, or even slowly sink. The better part of the cream it is that rises first to the surface, and it does so because, as water is about three per cent lighter than milk, so cream is about one-and-a-half per cent lighter than water, of which milk is chiefly composed. The largest globules rise first and fastest, the medium ones next, and so on; and so it is that the cream which rises in the first eight or ten hours will make finer butter than that which rises afterwards. It is from this first cream that the Americans make what they call 'gilt-edged' butter, which commands a fancy price in some of the cities of the Union; and they employ Jersey cows as a rule, because the average size of the cream-globules in Jersey milk is greater than in the milk of any other breed of cows.

The milk of cows, as of all other mammalia, consists of water, butter, casein, albumen, milk sugar, and mineral substances. The following is its average percentage:—

Water	87.25 per cent.
Butter	3.50 "
Casein	3.50 "
Albumen	0.40 "
Milk-sugar	4.60 "
Mineral substances	0.75 "

100 000

As will be seen in the following table of results obtained, the limits of variation in the composition of pure milk are considerable:—

Water	83.65 to 90.00 per cent.
Butter	1.80 to 5.20 "
Casein	3.00 to 5.00 "
Albumen	0.30 to 0.55 "
Milk-sugar	3.00 to 5.50 "
Minerals	0.70 to 0.80 "

And it will be noticed that, with the exception of the water, the cream volume varies more than any other constituent of the milk; so that cows in low condition, unless they are being fed on food rich in fats—in which event they will not remain in condition which, for milk-giving purposes, may be accurately described as 'low,' though at the same time they may be carrying very little flesh—cannot be expected to give milk of rich quality. Herein is involved a set of considerations of much importance in the management of cows, and I commend it to dairy farmers.

The complicated and delicate composition of butter is seen in the following triglycerides of fatty acids—the component elements into which the chemists have resolved it:—

Butyric acid	}	Volatile fatty acid.
Caproic "		
Caprylic "		
Cyprie "		
Myristic "	}	Real fatty acid solid.
Palmitic "		
Stearic "		
Rutinic "		
Oleic "		

In combination with glycerine they become *butyrine*, for the first bracket embracing the fluid and the second the solids fats. The flavour, colour, and aroma of butter have their origin in the first classification; while the body of the butter—the animal fat—is chiefly demonstrable to the second.

The element in milk next in importance to the butter is the casein, or curd, which forms the solid body of cheese. It is composed of the following chemical elements, according to the late Dr. Voonker's analyses:—

Carbon	53.57
Hydrogen	7.14
Nitrogen	15.41
Oxygen	22.03
Sulphur	1.11
Phosphorus	0.74

100 00

Enough has now been said to demonstrate the highly-complicated character of milk, and its comprehensive nature as an article of food. It is, in fact, the only known single article of food which contains all the elements necessary to the maintenance of life for a lengthened time, and in the best chemical and mechanical combination. Enough too, has been said, I hope, to illustrate the principle of kindly and generous treatment of cows; and particularly so when it is borne in mind that, in the domestication of cows, we have placed them under conditions which are essentially artificial.—*North British Agriculturist*.

THE BEST COWS.

There is no point in issue between the breeders of dairy cattle about which there is such a diversity of opinion as that of judging the merits of milk cows. With horses the watch makes the criterion with runners, and trotters, while draft animals can be tested by the dead pull, and carriage or park horses need most to please the eye. With beef cattle the scales and handling generally give very good satisfaction, though the butcher's block should be the ultimate criterion. When, however, we come to cows in milk, to determine which is the best, there are so many innate or latent virtues and vices, it is hard indeed to tell which is the best in a herd without long and patient study, and even then they vary so in each year's performance, the degree of one season is often over-ruled by the experience of another.

In the showing, of course, the examination upon which the judges must rely is of necessity the most superficial. To be sure, the cows can be milked, and the question as to which is the best when fresh, may be, with proper precautions against trickery, tolerably well determined, but after all the best cow is not the one that does the best immediately after calving, but, on the contrary, it is generally the one that does the best before calving. That is, the one that holds out best throughout the year, is the one that returns the greater profits to the owner. This is often proved by actual experiment to the utter amazement of the owner, especially the first season that the owner uses the scales. It is the old story of the tortoise and the hare.

Again, the question of quality of yield is of the greatest value only to the man who sells milk, while the butter-maker is more anxious about the cream. This point is difficult to determine on a short acquaintance with the cow. Practical science seems unable to solve the problem. Cream gauges and lactometers alike are misleading. Nothing but the churn seems to be able to settle the question outside of elaborate and expensive analysis. Having tried all the modern appliances for cheap and expeditious tests, we are inclined to think the mouth the best judge after all. With care and considerable practice most people can tell rich milk when they taste it, though there are many ways to deceive the tongue. Milk that has stood long enough for the cream to rise, and is then thoroughly mixed again, will taste much richer than it would when first drawn from the cow. This is probably owing to the lumpiness of the cream, which takes hold on the organs of taste more readily.

The men who have probably had the greatest trouble and accomplished the least in the matter of testing or judging are those who manage the various cattle clubs.—*American Dairyman*.

RULES FOR BUTTER MAKING.

The best churn is the one that will agitate most without pounding, at the same time creating a free current of air in the churn.

2. The cream should not be churned into a mass of butter, but the churning should cease when the butter gathers into small particles, say the size of apple-seed, so that the buttermilk can easily be separated from the fat by washing.

3. The butter should be thoroughly washed, and pure water or brine should be used. Working lowers the flavour and injures the keeping qualities.

4. Where cream is setting, the surface should not be exposed to an atmosphere much warmer than the cream.

5. The greatest percentage of cream can be got from milk that undergoes the greatest variation of temperature. Milk set at 90 degrees and lowered to 60 will produce about the same quantity of cream as milk set at 70 degrees and lowered to 40, the variation in both cases being the same; but the former will produce better flavoured butter. Farmers should therefore set their milk as warm as possible and let it cool to 50 or 55 degrees, afterwards not allowing the temperature of the cream or butter to vary much from these figures.

6. When farmers use the skim milk for feeding stock, the advantages of the system of separating the highest possible percentage of cream from the milk is greatly over-estimated.

7. More butter can be obtained from churning the milk than from any other system except the centrifugal.

8. A much larger percentage of cream can be obtained from newly calved than from old calved cows.

9. The number of pounds of milk required for a pound of butter varies from 20 to 30 according to the richness of the milk and the system of separation of the cream.

10. "Heavy milk" is a term applied to milk the cream of which rises slowly, leaving no distinct line of demarcation between the milk and the cream. Such cream is very thin. Heavy milk is produced by one or more of the following three causes: (1) In some breeds, such as the Ayrshire, the fat globules are small and specifically heavy, so that they either rise more slowly or not at all, and many rise only partially; (2) In all breeds, milk becomes heavier as the milking period is prolonged, especially when the cow is in calf; (3) All milks tend to become heavy when allowed to cool before setting.

11. If set at the same temperature, say 80 to 85 degrees, milk set in ice will produce 10 to 15 per cent more butter than when cooled with water to 50 degrees Fahrenheit.

12. By centrifugal separation about 12 per cent more butter can be produced than by cooling to near freezing point by ice, and about 30 per cent more than by cooling to 50 degrees with water.

13. Butter, if removed from the churn, without working, while in small granules, can be preserved fresh and sweet in brine almost indefinitely.—*The Farmer's Advocate*.

THE FORMS OF LEAVES.

At an April meeting of the Linnean Society, Sir John Lubbock enlarged on some points he had dwelt on in a popular manner in his lecture at the Royal Institution. He said he had long been puzzled at the reason why some plants have cordate leaves, more or less elongated, others palmate. Starting from a foliaceous expansion of a stem, the former was evidently the simpler type. He had suggested that the cordate shape was the earlier, from which the palmate was developed. The interesting consequence would follow, that if in the same genus some species were cordate and others palmate, the latter were of later origin. This explanation pre-supposed that the palmate forms, at any rate under certain circumstances, presented greater advantages. Sir John suggested that this might have reference to the power of self-support and of resisting wind. The weight of the leaf and the force of the wind might be considered as if they were concentrated on the central point of the leaf. Now in palmate leaves the centre would be nearer the point of support, and the resistance to any given force, therefore, would be more effectual. This point was illustrated by experiment. Broad leaves, however, were of two main types—ordate with veins following the curvature of the edge; and palmate or lobed leaves, with veins running directed to the margin. Now, the fibres constituting the so-called veins of leaves, contained elongated cells running parallel to the veins. Consequently the sap passing up the leaf stalk, and into the leaves, moved more readily along these fibro-vascular bundles, having fewer cell walls to traverse. It was almost like going along a road instead of across country. The fibro-vascular bundles then acted as pipes conveying the sap, and it is clearly more economical that they should go straight to their destination, rather than wind in a curve. As the sap passes more freely along the veins, the leaf also grows there more rapidly, which seems to explain the common-lobed form of leaf, with a wing to the point of each lobe.

Referring to some criticism on his views with reference to the relation between the size of leaves and the diameter of the stem, Sir John examined especially those of the conifers. Thus the spruce fir had shorter leaves than the Scotch fir, but they remained on much longer—say seven or eight years instead of two or three, and had a stem as thick or thicker. Amongst other interesting problems presented by leaves, he discussed the probable reason for the larch having deciduous leaves, and for the presence of two kinds of leaves on certain cypresses and other trees.—*Forestry*.

PRESENT LOW PRICES AND THEIR CAUSES.

The question of price is, of course, a complicated one, because many things may operate to affect the price of any given article, or of articles generally. You may have fluctuations of supply and variations of demand affecting the articles themselves, and arising merely out of commercial causes.

But you may have changes arising from political events, which may affect supply and demand, not only of articles bought and sold, but also of the money in which price is calculated. Thus, for

Whatever the changes may now be, the course of commerce has certainly given us much more steady prices.

Subsequent to 1849 the effect of the gold discoveries began to be felt, so that the average ratio of 1859 was 120, and of 1869, 119.

But the interesting point for our present inquiry is the consideration of the changes which preceded these discoveries. In his tract, "The Variation of Prices," published in the *Statistical Journal* for June 1865, Mr. Jevons expresses great doubt as to the cause of the very high prices of the early part of the century, and of the fall which followed so rapidly after 1809. He seems to think that the gold and silver, from whatever causes, were very redundant early in the century, and that thence arose a rise of prices here which caused a large drain of gold and silver to the East, and thus the previous advance of prices was turned into a decided fall; but he admits that the drain of gold and silver is greatest from 1814 till 1820—that is to say, after the fall prices had already begun. It is not easy to trace any very clear relation in this matter, and after balancing various considerations—as discovery, and increased yield of mines in Russia and Spanish America; the long-continued wars; the displacement of metalloids by paper currency; the restriction of trade; the hoarding of currency and dispersion of it by armies in the field—he winds up saying, "I assert the redundancy of gold in the early part of the century as a simple fact of observation."

In note C to his paper on the value of gold ("Investigations," &c., p. 110), Mr. Jevons attributes the fall in prices after 1820 to the want of increased supplies of the precious metals at a time when "modes of procuring, raising, and making other articles more easily and cheaply were constantly being discovered." And he argues that this fall must have continued but for the discoveries of gold. So the discoveries both checked a fall and caused a rise.—*Contemporary Review*.

NOTES ON TEA.

By PERCY SWINBURNE, late of Sylhet and Cachar.

The Cost of Opening Out.—Tea gardens in India depend: 1st, on the price of labour; 2nd, on the way the work is done; 3rd, on the nature of the forest or jungle which has to be cleared. But the price of labour is the all-important point.

In unhealthy places it is necessary to import Jungly coolies, as these are the only people who do not entirely succumb to the climate. The importation of Jungly coolies under a three-years' agreement costs from Rs. 80 to Rs. 100 per head, this being equal to about Rs. 30 per coolie per annum. Although these coolies are less liable to suffer from fever and bowel complaints than the others, they may still fall ill in great numbers when a new, unhealthy garden is opened out. For the first two years two coolies would barely do the work of one; and, calculating houses, medicines, and sick allowances, an unhealthy garden would cost Rs. 100 per acre extra for labour alone to bring it up to paying point. Then there is the unfortunate manager to be sent on a sea-trip, and, last, but one of the most important items, the small amount of work done for the daily wage must be considered, as if the coolies are not coaxed and petted they run away. In case of an unhealthy garden, situated in a place where no labour could be obtained, about Rs. 200 extra per acre should be estimated for as capital account, or total cost of opening out, up to time at which the garden clears its own expenses. But it has been already shown that if 6 maunds an acre can be safely estimated, Rs. 500 to Rs. 600 an acre capital would leave room for a profit of about 10 per cent.

In most parts of Assam and the Dooars, the North-West Province coolies and the Madrassies are almost unknown, and a thin, pale Desouali is sometimes seen as the sole survivor of a challoo. But in Cachar and Sylhet the bulk of the coolies are North-Westers. In Darjeeling there is abundance of Nepalese labour. The Jungly coolies are small, dark, and generally handsome, and though they are addicted to getting drunk and quarrelling on leave days, they are generally very tractable, natty and nice in their work, and are capable very frequently of building their own houses. The women are excellent pluckers.

The North-Westerner varies much, according to the district from which he comes and the *Jat* to which he belongs. Most of them come from the country about Benares, and are steady, hard-working, excellent hoeing men. The women as a rule are very clumsy and do no kind of work well. Their fingers, as the natives say, are "like toes," and very few of these become good leaf pluckers. They are a very thrifty people, and nearly starve themselves to save money. Their great ambition is to own a cow, and it is a good thing to encourage them in this.

The Madrassie is the most intelligent of all the coolies. He is as good at the hoe as at work in which more skill is required, and he makes an excellent hand in a tea-house, taking an interest in his work; and an Oriental who does this is indeed a *rara avis*. The women are equally good with the men, and not only pluck well, but work hard.

The local labour in Assam consists of hill people, called by various names—Arkars, Nagas and Kookies, and the Miahree, a people of the plain. These work generally only for a short time. Kaoharies who come down in batches from their own country, offer their services to the highest bidder. The Kaoharies are the most important of these labourers; they are very cleanish, and it requires considerable tact to get good work from them. Tall, pale, stalwart, but sneaking, mean and cowardly, they invariably try to get an unfair advantage from their numbers and co-operation; but those planters who know their language and work with these people speak well of them.

In Cachar and Sylhet there are also the Buteewallahs or villagers, Hindoo and Mohammedan, who at some seasons of the year will come to work in the gardens in large numbers. They are

chiefly useful for building, cutting and clearing jungle, and planting, weeding, &c., as the Hindoos will not hoe and Mohammedans are comparatively scarce. The pay to the Buteewallah is 4 annas a day for hoeing and 3 annas a day for other work. The coolies are paid by task work, but the rate of pay is generally as fixed in the Act (1882) Agreement, viz., Rs. 5 for men and Rs. 4 for women per month. Although local labour is cheaper than imported, it is as a rule unsatisfactory, as when it is most required it is often unprocurable, and the Bengalee is a shuffling creature, from whom it is almost impossible to wring out good work.

Starting Operations.—The site having been chosen, the contracts for labour, jungle clearing, and house building should be made in September or October, as contractors have frequently an in-py knack of delaying or forgetting their engagements, and it is very desirable to arrange with as many contractors as possible, in each section of the work, for the same reason. The rates vary in different districts, but for light tree jungle with dense undergrowth, and for bamboo land, to be cut clear or burned, so that the ground is ready for hoeing, the rate is about Rs. 10 per acre; for heavy forest, the cost of clearing will be considerably more, and for sungrass and light jungle less. Not a single tree should be left, and the land should be cleared about the end of November.

The sungrass for thatching should, after being cut, be stacked widely apart, in order to avoid the risk of fire. The lines should be placed near a river, stream, or tank, where the coolies can wash freely. A good height to make them is about 18 hats (that about 1½ foot) long by 16 hats broad. In Ceylon, where labour is much dearer than in India, roofing tiles cost Rs. 7 a thousand. About 9 to 10 tiles go to the square foot, and about half that number of bundles of sungrass cover the same area. With sungrass at Rs. 20 a thousand, thatched lines would be almost as dear as tiled ones, an allowance being made for the extra strength of roofing required for tiles. In Sylhet, four-sided roof (charchullie) houses are built for 10 annas a hat, so that an 18 hat house would cost Rs. 11-4, all material provided except sungrass. Sungrass costs from Rs. 10 to Rs. 30 a thousand bundles, each bundle to be of the thickness the two hands can span, thumb and finger touching.

In a house 10 hats broad, each hat takes 100 bundles of sungrass. This is thin thatching, but it is enough to keep out the rain; it should, however, be increased each year. A good allowance of room is 6 hats by 10 hats for two coolies, and if the 18 hat house is divided into three compartments, it accommodates six coolies comfortably. Taking the average cost of sungrass at Rs. 10 per thousand bundle, one hundred, covering 1 hat of house, cost Rs. 1, and the building and material for 1 hat would cost 10 annas; total, Rs. 1-10 per hat. If the sungrass were at Rs. 5 per thousand bundles, the total would be Rs. 1-2 per hat. One coolie occupies three hats, and it consequently costs Rs. 4-14 or Rs. 3-6 to house him. The builders, especially contractors, require strict supervision, as it is necessary that real cane, and not split bamboo, should be used; and the posts should be let into the ground to the extent of one quarter of their height, and the Kali bamboos, which form the framework, should be pucca, well seasoned, if possible, in water. If bamboo posts are used, they should be "barooah," and the arrah and turruks "macarh" and "jaice." The houses should be in a line with a road between them, and not less than 40 hats or 20 yards apart, to prevent the risk of all being burnt in case of fire. The arrangement also allows room for a kitchen garden round each house, as well as space for the cattle at milking and feeding time, in the evening and morning when they are not herded on the grazing ground. Machans should be fitted where the coolies wish, in their houses, and they should on no account be allowed to sleep on the ground.

Tea Seed.—It is still undecided which is the best kind of seed—indigenous, hybrid, or China. Gardens of China plant, especially in Darjeeling, sometimes realize the highest prices in the market for their tea, and it is asserted that the China plant gives the finest flavour, but the hybrid the greater strength. There can be no doubt that all teas, whether indigenous, hybrid, or China, develop a peculiar flavour of their own when cultivated on high elevations, and this flavour is considered by many Darjeeling planters to be most pronounced and more readily developed in the China plant. Soils, too, affect the flavour and certain soils suit certain kinds of plants; but the broad fact remains, which is better known to tasters than to planters themselves, that a certain fine quality and delicate flavour can be traced in the tea of indigenous gardens in all districts. This is the more significant, as every factory has a different system of manufacture; and if all were to manufacture in exactly the same way, the difference between the varieties of plants would be more marked. Next, the yield per acre of fine Assam, hybrid, or healthy indigenous is generally admitted to be greater than that of the China plant, although some assert that as much tea can be made off an acre of inferior hybrid as from any other kind of plant. The price of indigenous tea is found in the hills of Manipoor and Hill Tipperah, and doubtless, if search were to be made, it could be found in other hill districts. A little of this was found scattered over Cachar and Sylhet growing wild. Next in order comes the Assam indigenous, then the fine Assam hybrid, then the hybrid, then China. In buying seed, it is advisable to begin negotiations early in the year, to prevent disappointment, and it is better to pay a little more to buy seed from an estate which is well-known to give pure seed—that is, seed unmixed with inferior *jats*—than to take the chance of careless plucking. A guarantee is usually given as to condition, but seldom as to quality, which is more important. The history or pedigree of the seed should be given, as, for instance, if the seed is to be brought from C. garden, it should be described as (say) Assam indigenous, or Manipoor indigenous, from A. garden to B. garden to C. garden, the seed being traced to its untransplanted parent. The seed generally deteriorates with each removal, but it would not do so if the plant were well treated and perfectly healthy, and if the indigenous tea were always kept separate from the hybrid, so that the pollen from the flower of the one could not be carried to

THE INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA:—SATURDAY, JULY 4, 1885.

Health, Crop and Weather Report.

[FOR THE WEEK ENDING JUNE 24, 1885.]

General Remarks.—Good rain is again reported from Madras, where agricultural prospects are generally fair, and have improved in the districts in which they were most unsatisfactory. Harvesting is in progress in a few districts. In Mysore and Coorg rain has been general: the crops are in fair condition in Mysore, and promise well in Coorg.

In some districts of the Bombay Presidency, good rain has fallen, but in most places it has been insufficient for sowings. *Kharif* preparations are in progress in twelve districts.

Rain has fallen in the Berars, Hyderabad, and in most parts of the Central India and Rajpootana States. Cotton sowing is in progress in the Berars; and *Kharif* and *abi* ploughings have commenced in Hyderabad. More rain is required for the crops in parts of Central India and Rajpootana. Slight rain is reported from the southern half of the Punjab: *Kharif* ploughing and sowing are in active progress. In the North-Western Provinces and Oudh, slight rain has fallen in most districts: ploughing operations have commenced. In the Central Provinces, there has been good rain in most districts.

More or less rain has fallen throughout Bengal in sufficient quantities for present agricultural needs. More rain is, however, wanted in parts of Behar. Standing crops are growing well, and sowing of *amun* paddy is in full progress. In Tipperah considerable damage is said to have been done to the crops by floods; and in Dacca also some damage is apprehended on lowlands. The continuance of wet weather in Assam has proved injurious to the crops in Kamroop and Sylhet; but more rain is wanted for tea in Dibrugurh. Ploughing and sowing operations continue. In British Burmah the weather is seasonable, and ploughing is in progress.

The public health is generally fair in most Provinces.

Prices are still high in Bengal, and are fluctuating in the Punjab; elsewhere they are generally stationary.

Madras.—General prospects fair; slightly improved in Bellary and Anantapur.

Bombay.—Good rain in some districts, but insufficient for sowing in most places. Deficiency of water in the canals in parts of Sind. Preparations for *Kharif* crops continue in parts of twelve districts. Scarcity of drinking-water in one taluka of Dharwar, and of fodder in three talukas of Dharwar and two of Ahmednugger. Cholera in parts of eighteen, small-pox in parts of eleven, and fever and cattle-disease in parts of eight districts.

Bengal.—More or less rain throughout the province during the week; it is generally reported to be sufficient for all present agricultural purposes, except in parts of Behar where the fall has been slight. *Amun* paddy, jute, sugarcane, and other standing crops are now growing here, and the cultivation and sowing of *amun* paddy are in full progress. In Behar cultivation of *bhadai* crops has commenced, but more rain is much needed in some places. In Tipperah considerable damage is said to have been done to the crops by floods, and in Dacca also some damage in lowlands is apprehended owing to sudden rise of water. Cholera is still prevalent in some districts, and fever in Rajshahye and the Chittagong Hill Tracts, otherwise the public health is generally spoken of as pretty fair.

N. W. Provinces and Oudh.—Light rain pretty general. Ploughing operations commencing. Weather generally cooler, though still very hot in some places. Markets well stocked. Prices nearly stationary. Slight cholera continues in some districts, and has increased in Ballia. General health and condition of cattle good.

Punjab.—Slight rain in the southern half of the province. Health generally good. *Kharif* operations progressing. Prices fluctuating.

Central Provinces.—Rain plentiful, except in Nimar; and sowings are progressing. Cholera severe in Raipore and Bilaspore. Prices rising in Raipore, elsewhere steady.

British Burmah.—Cholera and small-pox in several districts, but not severe; cattle-disease in some districts, severe in Amherst and Bassein, but slight elsewhere. Ploughing progressing. Rainfall seasonable.

Assam.—Excessive rain has done some injury to some standing crops in parts of the district. Rivers falling. Cattle-disease not yet disappeared; public health good.

Mysore and Coorg.—Season favourable for preparing the land for transplanting paddy, good rain having fallen. Slight fall in prices of food-grains. Prospects of season and public health good.

Berar and Hyderabad.—Cotton sowings almost completed. Wheat 22 and *juari* 26 seers per rupee. Weather warm and sultry.

Central India States.—Weather seasonable. Health good. Prices steady.

Rajpootana.—Tanks and wells not low. Health good. Prices low. Weather cool; light clouds; high winds.

Nepal.—Weather still hot. Cholera increasing in the towns. More rain wanted for the recently sown rice.

Letters to the Editor.

TESTS FOR TIMBER.

TO THE EDITOR.

SIR,—Referring to the queries of your correspondent, A TIMBER MERCHANT, which appeared in your issue of the 27th instant, I beg to submit the following answers:—

First query.—By what method timber merchants or builders may ascertain at what season any timber (now lying in their respective yards) was felled in the forest? **Answer.**—If the timber is felled in summer, the starch granules would form superabundantly; because in trees the organic elements of nutrition, in the shape of starch granules, form during summer, and are stored away in the cells of the pith and of the woody cylinder, for use in the winter and in early spring, before the new leaves have acquired the strength necessary for the performance of their functions. This can be easily tested by a simple solution of iodine.

Second query.—What is the method of testing starch in any log? **Answer.**—A solution of iodine is the only recipe. But I don't know whether our timber experts, or conservators of forests, can recommend any better method.

Third query.—How should we detect wood that was felled while the sap was in flow? **Answer.**—Timber felled while the sap was in flow is of the worst kind. Experienced builders seldom use this sort of wood in building, because it decays very soon. To detect this kind of wood, a solution of iodine should also be used.

In short, if your correspondent wishes to know more on this subject, and will apply to me personally at my residence, I shall be glad to explain matters to him more fully.

HEM CHUNDRA DUTTA.

Rugboe Nath Chatterjee's-street,

THE JUTE INDUSTRY.

TO THE EDITOR.

SIR,—It is some time since a discussion on the Jute trade appeared in your valuable columns, and I would ask leave to renew the subject, with perhaps a degree of success, as regards the final issue. The prosperous times which were foretold by some of your correspondents have failed to make their appearance, and at present the horizon is still dark, and the clouds even blacker than before. Can some influential Jute-wallah not stir himself up, and push the matter, which, I think, is now all that is necessary? There are rumours regarding various companies which must be taken at their worth; but how much are these rumours worth? I am afraid that there is more truth in them than the agents care to acknowledge, and really some effort ought to be made at combination. It is true that some agents, who have their shareholders' pockets in view, have declared that they will stop so soon as

their stock of Jute runs down, and others have decided to run short time. These individual moves are not to be regretted, as they, no doubt, will help to reduce the evil of over-production, and enable the manufacturer to get a better price for his bag; but who will reap the benefit? Certainly not those on "short time" or "off" altogether, but those who are content to run, at present losing money, in the hope that they will derive the advantage of the better market at their neighbours' expense. But can these agents not have the foresight to perceive that, when individual Mills find they can manufacture at a profit, they will immediately start work, and flood the market as before? And I question very much whether the temporary rise will cover the losses of the running mills, for so soon as the Mills go off work, and on short time, resume their full working power, the values will recede to their old low level. Can combination not be arrived at, or are the shareholders of the various concerns content to see their money thrown to the dogs; to see their plant sold in a cheap market; to retire gracefully from the field of competition, their pockets so much the lighter, with the grim satisfaction of having kept at least one firm alive by a liberal allowance of Commission?

COSMOPOLITE.

Calcutta, June 24, 1885.

Editorial Notes.

THE quantity of new season's tea exported from China and Japan to Great Britain, from the commencement of the season to the 4th of June last was 12,713,592 lbs., as compared with 19,800,524 lbs. exported during the corresponding period of last year.

**

THE amount of Indian sea and land customs revenue, exclusive of the salt revenue, for the first two months of the current financial year, has amounted to Rs. 21,22,000, as compared with Rs. 30,47,000 during the corresponding period of last year.

**

THE Secretary of State for India has approved the action of the Madras Government in directing the closing of the works for the manufacture, on the excise principle, of salt in the district of South Canara. The reasons given for this action are, that the arrangements having been in force for upwards of seven years, a sufficient time has elapsed to give the scheme a fair trial, therefore it was nothing but right to abandon the effort to introduce the system into a district for which it is apparently unsuited.

**

IT is stated that the Bombay exhibits sent to the Antwerp International Exhibition formed a very interesting collection. The Bombay Court appears to have been in a very forward state of preparation on the opening day, the 2nd ultimo, and was honoured by a visit from their Royal Highnesses the King and Queen of the Belgians, the Count and Countess of Flanders, and their son, Prince Banduin, the heir-apparent to the throne. Their Majesties expressed themselves much gratified with the beauty of the articles exhibited, and promised to pay a longer visit on a future occasion.

**

OUR readers may remember that a short time back we referred to a proposal said to have been under consideration, which had for its object, the transfer of Forests from the Home Department to that of the Revenue and Agricultural Department. We now understand that this proposal has come to nothing. A local contemporary very correctly remarks:—"It would be interesting to know how this has been effected. The anomaly of the present arrangement is notorious, and the marvel is that it has lived so long. One would have thought that the Home Department would have been glad to get rid of what it must regard as an extraneous encumbrance." We should have thought so too.

**

A CORRESPONDENT from Colombo, sends the following telegram to a local contemporary, under date the 20th June, and to which we invite the special attention of our Tea merchants:—"The Melbourne Tea Market is firm for all Indian kinds, but

great complaints are made as to the unfavourable out-turn of breaks, as compared with the sample packages. There is sometimes a difference of from two to four pence between the value of the breaks and the sample, causing great loss of prestige to Indian tea. Confidence in the reliability of the sample packages is thus lost. Strict attention is needed to this matter; also smaller packages are required. All China tea comes in half-chest boxes, which are less liable to breakage and handier to transport."

**

THE late rains have improved the indigo prospects in Bengal, and manufacture has commenced in one or two factories. Good rain has fallen in the Midnapore district, and prospects are generally fair. Seasonable rain has also fallen in Tirhoot and Chumparun, though a further fall would still be acceptable in some places. Mahai has commenced in a few factories, but will not be general till about the 5th or 6th of next month. Very little rain has fallen in Chupra, and the season will probably be late and the outturn deficient. Good rain has fallen in Shahabad, enabling the planters to commence their sowings; and rain has also fallen in the Benares provinces, where it was much wanted. There is, however, but little news from the North-West, though it is said that the area under cultivation both there and in Benares is less than last year.

**

THE gold trade of Melbourne has been reviving of late, as we find that the export of this metal from Melbourne during the month of May of this year amounted in value to £788,747, which is the largest amount on record for many months past. But this is counterbalanced by a still larger quantity being imported, thus making a decided drag on the trade, as imports are on the increase and exports are going down perceptibly. The increase in the value of imports during May was much larger than that of the corresponding month last year, exceeding it by £73,089; while the value of the merchandise exported compared unfavourably with that of last year during the same period, it having decreased by £96,692. The greater portion of this decrease is ascribed to diminished shipments of bread-stuffs and agricultural produce generally.

**

MR. BOSWORTH SMITH, the newly-appointed Government Mineralogist at Madras, has been inspecting the mineral collection in the Museum at the city. He does not think that it is a perfect index to the natural wealth of the Presidency. He considers the iron specimens best, the copper specimens he only considers interesting from a scientific point of view, but that they are too few in number to be of much value. He is reported to have expressed much surprise at the few specimens of lead collected in the Museum, considering the many deposits of this metal that occur in the presidency. He has suggested sections of the many fine marbles and limestones, as well as the igneous rocks used for building purposes, should be studied microscopically in order to test their durability, and that the collection of standard minerals from foreign countries require re-arrangement, and, in some instances, to be re-named, as the wrong names had been given.

**

THE pre-eminence of England as a coal-producing country would seem to be likely to be overthrown in the near future by one of her own children. The New South Wales coal-fields have been surveyed and discovered to be of enormous extent. For hundreds of miles along the coast the seams of coal can be traced, and it has already been worked at different altitudes from 450 to 1,500 feet above the level of the sea. Altogether coal has been found to exist over 25,000 square miles of country; while England's annual output of 120,000,000 tons is derived from a total coal area of 4,000 square miles. More than this, the lower strata of New South Wales coal date from a more distant geological epoch than any that have been worked in Europe, and the coal therefore is of unrivalled excellence. In addition to these enormous advantages the mining industry of New South Wales will owe much of its future prosperity to the fact that the coal fields are everywhere situated within easy reach of water and railway communication, and that an abundance of iron ore, limestone, and fire-clay are found in immediate juxtaposition to the seams of coal. Altogether it would seem impossible to exaggerate the prospects of the New South Wales coal-fields.

THE Report on the Meteorology of India in 1883, which has been courteously placed at our disposal by the Meteorological Department, is a very complete record of observations taken all over India, and is of peculiar interest. To the student of meteorology, it will present an endless variety of data for speculation, as it is only from the collation of meteorological readings that we can hope for any accurate understanding of the climatic influences of a country. In this respect the present report is exhaustive. We notice one new feature in the report, viz., the record of the duration of bright sunshine. The means of a sunshine recorder. This instrument has hitherto been used only at Calcutta and Allahabad, and for a month or two at Jeypore. It is of some importance to have a measurement of the duration of bright sunshine, as it is a more direct measure of the amount of solar heat of the earth's surface, than the register of its mean maximum intensity. The instrument is ingeniously contrived, and promises to supersede the sun-thermometer. The report contains interesting charts showing the mean distribution of the temperature, atmospheric pressure, and the direction of the wind, with charts of the rainfall, and the changes preceeding, accompanying, and terminating two rainy periods, and cognate subjects.

THE Government of India, in the Home Department, have addressed a Circular letter to all local Governments and Administrations, enquiring, with reference to paragraph 83 of the Forest Department Code (2nd Edition), whether any particular form has been adopted for the record of rights and privileges admitted in the several Reserved Forests, or whether it is left to the Forest Settlement officer to record such rights and privileges in whatever form he chooses. If the former procedure has been followed, it is requested that the Government of India may be favored with a specimen copy of the form adopted. The point that gave rise to this Circular, was a statement containing a record of the rights, admitted by the Forest Settlement officer, on behalf of Government, in the Annamalai reserve, Coimbatore district, Madras Presidency; and it is considered that it would be an advantage, if similarly complete records of rights in reserved forests were readily available for purposes of reference, in connection with every such forest in the several provinces. That the work of control is much facilitated when the forest officers can refer to some such clear statement as that drawn up in Madras, instead of having to refer to a confused mass of vernacular records of settlement, as has to be done in some provinces.

THE Pioneer says:—After having had occasion to remark lately, that the notices of ejectment in Oudh for the approaching revenue year had reached the monstrous number of over 85,000, we turned with some interest to the Revenue Administration Report of the Province, just issued, to see in what light the question would have struck the Government. The report covers the year ended on the 30th September last, and touches a number of small questions of the most slender interest. But the one subject of real importance, Oudh tenant-right, is dealt with and disposed of in a single brief paragraph. "The Lieutenant-Governor and Chief Commissioner does not take up any close examination of the statistics..... It is sufficient to say that the figures in the report strengthen his belief that the Oudh rent law, in regard to tenant holdings at-will, might be amended with advantage to the tenantry and without real detriment to the interests of the landlords." No one will be disposed to question this conclusion any more than the following:—"The steady increase of ejectments indicates a practical insecurity of holdings, and a constant shifting that can be hardly otherwise than economically disadvantageous;" and we may well believe that among the tenants who had formerly rights of their own in the land, "the uncertainty and instability of their year-by-year occupation must, if it continues, as it probably will, keep up a feeling of discouragement and discontent." But the hungry sheep will not be fed with the bare annunciation of perfectly obvious truths. If the Government, while admitting all these evils, hints also that they are within reach of remedy, it is surely bound to do something more. It is said that the question is "under consideration," and indeed it would be singular if it were not; but consideration is not the means for meeting increasing evils which are yearly growing more difficult of remedy. Is it the intention of the Local Government, after all its inquiries, and the facts which they have established, to sit still and consider until the old yeomanry of Oudh have passed into the condition of the Behar ryot? It would almost seem that it is.

THE following is a summary of Messrs. William James and Henry Thompson's fortnightly circular of Indian Tea, dated Thursday evening, 4th June, 1885:—"Since the 31st May 9,000 packages have been catalogued for sale, including 105 packages of new tea, 2,480 packages from Ceylon, and 1,300 packages of re-printed and second-hand tea. The quiet tone still prevailing in the country has been reflected in the market, and the auctions have passed without animation; prices, however, have been fully maintained for all good teas, but have inclined to favour buyers of common qualities, especially of Broken Tea and Fannings. About 100 packages of new season's growth were sold on the 1st instant, at fair prices considering the indifferent quality of the tea; the quotations ranged from 8d. to 1s. 3½d. per lb. The second sale was held in Calcutta on the 28th May, and about 5,500 packages were sold at an average of 10½ annas; we are advised that the quality was good, and prices were steady. At the corresponding sale last year, 3,500 packages were sold at an average of 7 annas 10. Shipments of 1885 crop are rather in advance of last year. The deliveries during May were 4,214,000 lbs., and the stock in the Bonded Warehouses is reduced to 14½ million lb.—7½ millions less than last year. We estimate, however, that about 3½ millions over the average were cleared in consequence of the duty scare, which makes the real deficiency 4½ million lbs. The trade has not yet shown any apprehension of scarcity, and many hold that, as in other produce markets, it will be found possible to conduct the business without the heavy stocks which used formerly to be carried. This must be borne in mind in calculating the effect upon the market of this unusual depletion of stock. The proportion of Indian and Ceylon Tea consumed in the United Kingdom during the past 12 months has risen to 40 per cent, as against 35 per cent in 1883-84, and 33 per cent in 1882-83."

THE Madras Missionary Conference have taken occasion to submit a memorial to the Governor of Madras, in which they have taken exception to certain recommendations of the committee appointed to report on Abkari administration. The sentence that has been particularly objected to, occurs in Mr. R. A. Dalzell's second report, and runs as follows:—"The excise revenue has more than doubled itself during the past sixteen years, and may, I believe, if carefully developed and regulated, so as to bring about some sort of uniformity of excise duty both on arrack and toddy, be moulded into an equally convenient engine of taxation, as the salt tax, being raised or depressed, in accordance with State necessities." (p. 10.) Much stress is laid on this "engine of taxation," which is to be "carefully developed." The Madras Government, however, distinctly repudiate, as forming any part of the policy of that Government, the design to convert the Abkari, or tax on liquor, into a "convenient engine of taxation." The Missionary Conference have made certain remedial suggestions, which have been taken up *seriatim* in a resolution by the Governor of Madras. The resolution winds up with the following:—"His Excellency has to observe that the provisions of the Abkari Bill, which is now under the consideration of the Legislative Council, and may shortly be expected to become law, will amply provide for the preventive establishments necessary to prevent illicit practices in connection with the liquor trade."

No one will doubt that the cause taken up by these reverend gentlemen, viz., the restriction of the liquor traffic, is a worthy one; but it seems to us that the liquor traffic can be best restricted by imposing a heavy tax on its manufacture, and this appears to be what the Government have in view by making the excise revenue a "convenient engine of taxation." Whatever be the terms of the Abkari Bill, the ultimate result of the memorial will have one good effect, viz., it will go far to render the supervision of the liquor traffic stricter in the future than it has hitherto been, as seems evident from the Governor's resolution.

THE prospects of sugar-cane culture in the Madras Presidency are not encouraging. Mr. Benson, Agricultural Reporter, says that the recent fall in the value of sugar has caused severe loss to sugar growers in the district, and that a good many are giving up the industry. A good deal of the cane he saw was

derived from rattoons, growers having been loth to incur the expense last year of planting sugar-cane fields. The extent of the losses may be gathered from the fact that a short time ago jaggery was worth Rs. 21 to 22, per candy of 500lbs., while at present it is only worth Rs. 14 to 15.

To the regular grower the cost of raising a crop of sugar-cane may be put down at from Rs. 90 to 100, and for a crop of rattoons, Rs. 70-80. The cost of making jaggery has to be added to this, and is somewhat as follows:—

	Rs.	
For a first crop	60	
For a ratoon crop	40	
Thus making in all		
	Rs.	Rs.
For a first crop	150	160
For second, or ratoon crop	110	120

which at present prices is unremunerative, except in so far as it affords the ryot a useful outlet for his labour. In fact, judging from Mr. Benson's report, the sugar industry is likely to die out in Madras. Another reason for the fall in prices may be found in the fact that Mr. Benson noticed that the jaggery made in the Godavery district was of an inferior quality, and compared unfavorably with that manufactured at Poona. It may be observed that at Poona very primitive methods were adopted, but Mr. Benson did not particularly observe the process followed, which secured the superior result, as he did not, at that time, know anything of the local jaggery manufacture. The correspondence contains no suggestions for improving the present depression in the sugar industry.

A CONTEMPORARY makes the following very sensible remarks on the subject of cattle-breeding in Bengal, to which we would invite particular attention:—"The newly-appointed Agricultural Department of Bengal should take up the subject of cattle-breeding in right earnest. That bullocks and kine are deteriorating and disappearing very fast in Bengal, no one having the slightest knowledge of the state of things in the Mofussil will have the hardihood to deny. Milk and all its preparations have not only become dear but scarce. The decrease in the yield of milk has been gradual and constant, and this can only be accounted for by the supposition that the species have deteriorated, or their number has decreased. The *goulas* mournfully declare that both these evils are at the root of their misfortune, that now-a-days they can scarcely see the face of a healthy strong calf or a fat milch-cow, and that after an interval of 8 or 10 years, that fell scourge, the *basanta* carries away 99 per cent of their cattle, and ruins them within 4 or 5 days. This has been their representation since the last two decades. It was, we believe, in 1870, that the attention of the Government was directed to the fact of a fearful epidemic amongst the cattle of Bengal, and a Commission was appointed composed of a few Europeans, and one native gentleman. What they did, neither we, nor anybody else, we believe, know. One of these Commissioners, Dr. K. Macleod, obtained a reward of Rs. 500 from the Government for compiling a treatise on the native mode of treating cattle-diseases. But in spite of the Commission, Dr. Macleod, and his treatise, the number of cattle has not ceased to decrease nor the species to deteriorate. The subject is of vital importance to the nation, for cattle is our only wealth, and we die with our cattle.

BENGAL cattle is weaker, leaner, and more sickly than the people of the country. One of the chief reasons for this state of things is want of fodder. Grasses for cattle are not cultivated here as is done now in other parts of the world. The people chiefly depend upon the straws which they even cannot collect properly, and a large portion is left in the fields for want of sufficient funds. This year the cultivators in most parts of Bengal have been able to gather very few straws on account of bad harvests, and the result will be the starvation of their cattle. The cows and bullocks in this country are thus fed simply to keep them in existence, and generally kept on half rations. On the other hand, they are made to work hard, a pair often doing all the business of a farmer having fifty biggas of arable land. Under these circumstances, the poor, hard-

worked and famished cows and bullocks die of sheer exhaustion like our prisoners, and fall an easy prey to such diseases as the *basanta*, the *parakina*, the *tilla*, &c. The Agricultural Department cannot do a better service to the country than by introducing such grasses as the guinea, the sorgho, the *jai*, *Moora* amongst our cultivators. Cattle better fed and strengthened, the people will be in a better position to meet the multifarious demands of Government in the shape of taxes, rates, cesses, and duties. Another potent reason for the deterioration of the species is the disappearance of healthy, strong bulls from the country. And the Government and its *issane* officers are responsible for this mischief. In accordance with the injunctions of the *shastras*, a male calf is usually set at large during the funeral ceremony of elderly people. These calves immediately become common property, and they are treated with respect by the community. The charge of maintaining them was borne by the community, and, in course of time, these, simply by their mode of living, became strong, half wild, huge bulls. That the object of this injunction of the *shastras* was to improve the breed, we for one have not the least doubt. But where are these sacred bulls now? They are rarely to be seen in Bengal. In the rutting season, the ryots carry their cows from village to village in search of a bull, and if they find a hard-worked, lean, and half-famished one, they consider themselves fortunate. A healthy breed can never be expected from such a breed, and no amount of good feeding will improve a calf of such a parent. No wonder then that there should be an epidemic among cattle, and that the yield of milk should gradually decrease.

We extract the following paragraph from the letter of the Ootacamund correspondent of the *Statesman*, dated the 13th ultimo:—

"The unnecessary severity employed by the Government officials on the Nilgiris, in the collection of land revenue, has for some years been scandalous. Now that such severity has terminated fatally in one case, it is hoped Government may be inclined to look into the matter, and temper the misguided zeal of officials anxious to earn a reputation for efficiency. The Deputy Collector the other day issued a warrant of arrest against the person of a Canarese gardener, who had unfortunately fallen into arrears. The man was in bed, in a critical state, suffering from pneumonia. The process-server was remonstrated with when preparing to execute the warrant, by a gentleman who happened to be near at hand, and the man's friends guaranteed payment of the amount due. Notwithstanding these promises and assurances, a stretcher was procured, and the defaulter carried in a semi-nude condition through wind and rain to the Deputy Collector's office, and there allowed to be exposed to inclement weather. Finding the man in *extremis* he was hurried back—but the exertion and exposure were too much for him, and he died within half-an-hour of reaching his home. The process against the person of a defaulter can by law only be issued when his property is insufficient to liquidate the Government claim; or where the defaulter is wilfully withholding payment, or has been guilty of fraudulent conduct to evade payment. None of these circumstances are present in this case, which demands a searching enquiry at the hands of Government. I think that, even technically, the arrest cannot be justified."

If the facts are correctly reported, it is difficult to write calmly of an instance of such wanton disregard for human life. A searching enquiry should be instituted into the circumstances touching the death of the deceased.

A CORRESPONDENT from Moorshedabad, under date the 22nd June, sends the following to the *Statesman*:—

"A gentleman in the district has been making experiments in fibres recently, and intends cultivating largely later on. He tells me that he has been very successful with the *Hibiscus asperatus*, or *dhennus*, which he says yields a fine and strong fibre. I saw his plantation and was struck with the vigorous growth of the plants, attaining eighteen inches in height in the course of two weeks. It seems very easy of cultivation and does not require weeding, being strong enough when once it has appeared above ground to exclude all intruders, and growing faster than jute, with which the fibres compare very favourably in length and appearance. I gather that the preparation of this fibre is similar to that of jute.

The following is the process, as explained to me by the planter referred to :—

The *Alchornea* being ripe, the stems are cut down close to the roots, made up into bundles and steeped in a neighbouring *jhil*, with bamboos and lumps of turf laid over them to keep them submerged. Here they are watched from day to day until the proper point of decomposition has been reached—which is ascertained by trying the bark with the nail. This being attained, a number of men stand up to their waist in the water, each taking up as many sticks as he can grasp, removes a small portion of the bark next the roots. Then, grasping them together he strips off the whole from end to end with a little dexterous management, without breaking either stem or fibres. Having prepared a certain quantity in this half state, he next proceeds to wash off. This is done by taking a large handful, swinging it round his head and dashing it repeatedly against the surface of the water, and drawing it through towards him so as to wash off the impurities. It is now wrung out to remove as much water as possible, and hung on lines in the sun to dry.

This was the process carried out last season, but I learn that a machine is to manipulate the fibre as soon as the plants are ready this year, and it will be interesting to know the result as a commercial enterprise. The grower has great hopes of the fibre proving superior to jute in color and strength. If this is the case, I have no doubt its cultivation will be a success pecuniarily, as it is as easily prepared as the latter, and costs less in cultivation.

The *Albizia Rooulentus* is not new to us as a fibre-producing plant. The foregoing communication is interesting in so far as it concerns the easy cultivation, rapid growth, and small cost of growing the plant. Should it prove superior to jute in color and strength, it may replace that plant commercially.

* *

It will be remembered by our readers that not long ago a suggestion was made by the Director of Public Instruction, Madras, for the establishment of a school of Forestry in connection with the Agricultural College at Saidapet. Acting on this suggestion, the Government of Madras called for the opinions of the two Conservators of Forests—Major Campbell Walker and Mr. Gamble—on the scheme. These have now been received, and we find that both these officers are opposed to the proposal. Their arguments against it are based upon sound reasons, which are, that there would be very little chance of turning out efficient men from a school of this nature at Saidapet, which place is not suited for such a purpose. The Imperial Forest School at Dehra Doon is very highly spoken of by both officers, as affording a means of imparting the best theoretical knowledge, combined with practical lessons in forestry, and they see no reason why students from Madras should not be sent there, as they are from other parts of India. It is further stated that "the mere circumstances of travel, mixing with forest officers from other parts of India, and the healthy spirit of emulation engendered at the Dehra School, tend to open the men's minds, develop their powers of observation, and foster a feeling of self-respect and pride in their profession which cannot fail to do much good." In fact very strong arguments are used by both officers against the establishment of a Forestry School at Saidapet, and neither of them are prepared to give the measure any support. Mr. Gamble says that "If eventually a large increase of work, and the number of subordinates, make a Madras Forest School necessary, it is not at Saidapet that it should be instituted, but at some place like Coimbatore, where it would be close to the most important forests and plantations, both of the hills and the plains."

* *

It will interest our readers to know Major Walker's estimate of an ideal Forest Ranger. Here it is :—"Much practical experience, and intelligence and education of a high order, are necessary to make a good Ranger. Besides practical forestry in all its branches, he should be a good surveyor and draughtsman, be able to level and construct forest roads, bridges, timber slips and houses. This necessitates an acquaintance with higher mathematics, mensuration and trigonometry, besides which he should have mastered the elements of botany and physiology, and be intimate with the system of Land Tenures and the Revenue and Criminal Law, so far as it refers to forest matters not provided for in the Special Act, with which, and all departmental rules, he must, of course, be fully conversant. If we

add to the above, energy and thorough trustworthiness, we shall have formed some idea of the ideal Forest Ranger." We sincerely hope Major Walker will realize his "ideal;" but we have some doubts about it, especially when it is remembered that the brilliant prospects held out to this "ideal" are—a salary of between Rs. 50 and 125 per mensem!

* *

MR. E. C. BUCK, the Revenue and Agricultural Secretary to the Government of India, while in England recently, is reported to have made the following communication to a representative of the *Ironmonger*, on the subject of agricultural implements in India :—

"The story of agriculture in India is a long one, but that relating to agricultural machinery is a short one. I do not wish to say anything that may discourage manufacturers, or that may tend to drive them out of the field, but it will be as well to state at the outset that, under existing circumstances, there is, I believe, little chance of the natives of India taking to machinery in a general way for a long time to come, or if they do, at present it will only be to a very limited extent. This is not to be wondered at considering all things. First, there is the cheap and abundantly-supplied labor market, with wages at about 2d. per day, or 1s. per week. Compare this with the cost of labor and the yet not very extensive use of machinery in this country, and you will get some idea of the difficulty in the way of persuading the natives to adopt machinery. The only possible chance at present, I believe, is to supply them with machinery to do such work as cannot be done by hand, such, for example, as small sugar-crushing mills. For treating the sugar-cane the natives have always, of course, had a machine, but, though it was crudely constructed and very defective, it has involved fifteen or twenty years of patient work to bring a machine down to the requirements of the natives, making at the same time a really good machine, which when used once by the natives is sure to be appreciated. Then, not only this, but the prejudices or ideas of the different districts have had to be conquered, and the machine has had to be modified or adapted to the peculiarities of the district in which it has been introduced. Such mills the natives buy in tens of thousands. Now this proves, I think, better than anything I could personally state, that the natives will use a machine if it is brought down to them and adapted to their requirements. It is the greatest possible folly on the part of Europeans to suppose that any such thing as educating the natives up to Western machinery is to be accomplished at one stroke. I could mention firms, were it desirable to do so, who have sent out machinery with that object; and the Government of India has also done its best to induce the natives to take and try the machines. Yet, no, not a vestige of success has attended the effort.

"But, as I said just now, I do not wish to throw cold water upon European energies. On the contrary, I would only endeavor to set the manufacturers right. It is utterly useless for any European firm to trust simply to agents or branch houses out there. The market has to be created, let it be remembered, and the only way of creating it is to go in and out among the natives, to travel through the country, and thus become thoroughly conversant with their manners and customs, and their prejudices, too. Then, if a machine can be produced which will save labor, and effect at the same time a reduction in the low cost of such labor, there will be a splendid opportunity for doing business with the natives. Let me illustrate this by referring again to the sugar-crushing mill. The old mill was mostly of stone and its operations were of the pestle and mortar kind. It was also very heavy, too heavy to be lifted or carried about from place to place with convenience; and, moreover, it took two bullocks to work it. Now, the machine is light, and can be carried by two men and worked by one bullock.

"Now, take another thing. Here is a tool which is used by every native. (Here Mr. Buck produced a bill-hook.) It is not an elegant affair, nor is it used exactly the same in shape and size in all districts, as it varies somewhat, and is called by many different names, according to the district; but it is a fair specimen of what is used in the district where I reside. You will see that it has a very short handle; that is due to the fact that the natives, when at work, sit down, even when felling trees, and it will be very obvious that they could not work with a long-handled tool. With a view of seeing what could be done in this tool alone, I went to a firm of manufacturers, and asked them to make me some like it. Yes, they said, they could do so, and turn out a nice bright article, with a polished handle and a bright, sharp blade.

"No," I replied, "that is just what you must not do. If I were to make such a tool to them they would not only never use it, but they would be frightened at it. Make them as nearly like the pattern as you possibly can, dirty-looking and old, and at the lowest price, even if the profit is only small." And that is what must be done in all cases. It is no use whatever to attempt a large profit at first; on the contrary, I should not be surprised if manufacturers made a loss for a while, and they should, I think, be prepared to make it, because the natives have no capital, and they will only make purchases of what they cannot well do without.

"The time may come, however, when better tools and implements will be required. The Government is doing all it can to educate the natives, and it is reasonable to suppose that when they understand these things better, there will be some interest taken and a desire evinced for better appliances. But I must add that these new and better tools must not be introduced by the Government. There are always, of course, a hundred failures to one success, and the native mind is not favorable to experiments. He is quite sure he knows his business better than anybody else, and resents anything like forced instruction.

"With regard to the planters, circumstances are, of course, quite different. As a rule they are men of capital and of some education. They know the value of machinery, and their oxen being altogether of a superior, stronger kind, they are able, supposing them to be willing, to use what the natives, because of their only half-fed and not very strong bullocks, are unable to use. Yet even with them the low price of labor acts as a deterrent in the employment of machinery, and at best the market is very limited and slow. The only part of India where labor-saving machinery has as yet been successfully introduced is in Burmah and in Assam, in which latter place they take reapers for jungle grasses, and mowers for the low grasses. But, as with the planters, the scope for European enterprise is not wide, and manufacturers will find it best to make a bid for the native market. What this market may become some day if properly worked may be judged from the fact that there are no less than 40,000,000 of holders of land, each holding only five acres."

A FEW AGRICULTURAL IMPLEMENTS FOR INDIA.

(By Sayed Sakawati Hossain, Bengal Agricultural Department)

THE condition of Indian agriculture is primitive: the same plough and the same harrow, and it may be said, the same "everything" are still in use, with which agricultural operations were performed in the olden times. The recent discoveries and new inventions for facilitating agricultural labor are unknown in this country. An Indian cultivator is said to be a conservative of conservatives, and is at times unjustly reproached for want of enterprise. But it must be said that circumstances beyond his control have mainly contributed to the present backward condition of Indian agriculture. Before the advent of the British Power, the fiscal system of the country was very faulty, and the security to the cultivator for the enjoyment of the fruits of his labor was insufficient, not to say precarious. Such was decidedly the case during the Mahomedan supremacy. In the days of Hindoo supremacy, wants were few and harvests plenty. India in those peaceful days was little in communication with other lands, and her commerce was confined to a few countries. The necessity for over-production was not felt, as the fertile soil of India yielded freely, and with little labor, what her population needed. But all this is altered now. India is no more a secluded country shut out from all others; her ports are free, and her merchandise finds ready sale in foreign markets. We are living in the days of incessant progress and advancement, when nothing is stationary. The population is ever on the increase, while the simple habits of old are being slowly but surely replaced by expensive ones. New tastes are being acquired and new ideas of living learnt. This change, though silent, is none the less sensibly felt, and attention will now have to be directed to find means to increase the produce of the land. India at present is purely an agricultural country. Other industries are few and little followed. Agriculture is not only her main source of food supply, but it has to supply all other wants, and now, when more is wanted, the land is beginning to yield year by year diminished crops. The complaints of

drought and scarcity of water from parts of this continent have become more frequent, and the general prosperity of the country appears to have been affected. The aid of science and arts, hitherto not required in the pursuit of agricultural industry, has now become a necessity. The slow but certain process of exhaustion has to be arrested, and the land is required to yield more than hitherto to supply the increasing wants of an increasing population. The introduction of new methods and new appliances will sometimes fail to produce satisfactory results, but experience and success can only be achieved by sacrifice and failures. Of course the hasty adoption of new methods is to be deprecated. Progress is always slow, and slowly must we advance. It is unfortunate that agricultural industry in this country should be chiefly pursued by ignorant ryots of limited means, who are, at the same time, wanting in the spirit of co-operation. For success in any industry, intelligence and capital are necessary; and in both of these our present class of cultivators are sadly wanting. But however much we may deplore this state of things, we must accept the situation. I propose in this paper to point out some of the implements and appliances well within the means of an average ryot, the adoption of which may lead to better results. First and most important of the implements which I would advise him to adopt, is the improved plough. With the native implement, mis-named a plough, much time and labor are wasted, and the results obtained are unsatisfactory. The native plough merely scratches the ground; while the object of ploughing is primarily to pulverize the soil; and this cannot be done with any degree of efficiency by the use of the native implement. I would not insist on inverting the furrows, but the soil must be dislocated, or else the loosening of it cannot be properly effected. With ploughing and cross ploughing some result, I grant, is obtained, but at the expense of much valuable time and labor, at a period when both are precious commodities. With the improved plough, such as those made at Cawnpore or Madras, more work will be done at less expense, and in less time. The cost of such a plough is not by any means prohibitive. A native plough costs about one rupee, and the improved plough six rupees. The native implement requires constant repairing, and some parts of it replacing; while the quality of the work done is inferior.

Next to the plough is the harrow. This implement is a very necessary adjunct to the improved plough; for without it the desired pulverization of the soil is difficult. I would recommend a light zigzag harrow with teeth of iron slightly inclined forward. The frame may be of light wood so as to reduce its weight to suit the weak draught animals used in this country. This harrow will serve the purpose of pulverizing the surface; giving a good seed bed for germination of seeds; of smoothing the surface, and of gathering and shaking out surface weeds. It will also serve the purpose of covering the seed when used for that object. Of course this light harrow will not reach the whole depth of the plough, but this is not necessary, inasmuch as the growing plants will be strong enough to send their roots down through to the loosened soil, and a fine tilth for the germinating seed is all that is necessary. A light wooden roller is also one of the implements that a cultivator ought to have. Firm seed beds are required for some crops, and the native methods of using a wooden plank called *chawla* in this part of the country is hardly sufficient. A trunk of a tree made into a smooth cylinder will quite answer the purpose of a roller. With the harrow and the plough, costing altogether Rs. 9 or 10, and a cheap country-made roller, preliminary operations of preparing the soil for the reception of seed will be satisfactorily performed.

In sowing, it is always more economical to dibble than to drill, and to drill than to broadcast. This is only a general principle, not always practicable. Of course, an Indian ryot is not to learn how to sow seed. In that, I take it, he is an adept. For rice it would perhaps be always desirable to broadcast seed; but still I think sowing in furrows will be of advantage for subsequent treatment of the crop. In countries where labor is cheap, as in India, dibbling might be often resorted to than it is. Dibbling merely consists in depositing seeds in holes made with wooden nails. Drilling is not quite unknown in this country, as may be imagined. Some of the ryots

here attach a bamboo tubing, with a funnel on the top of it, to a plough, and as the plough proceeds, a man goes behind dropping seed into the funnel, and the seed passes on to the tube, from which it falls on to the ground. This mode of drilling is inexpensive, but hardly efficient. With some slight improvement in this native method, it could, I have no doubt, be made more efficient. The native plough is undoubtedly a very good hoeing implement, and may be used for that purpose, especially in maize fields. The ordinary *khoepee* of the country, with some slight alteration, can be easily converted into a good hand hoe. It has been found by experience that a man can work better standing than sitting, and hand hoes might be fitted with long wooden handles, so that they can be used standing. A long wooden fork with two or three iron prongs will be a very useful and convenient implement in the hands of a cultivator, and will serve various purposes.

The native method for reaping is crude and simple. Of course, I would not, in the present condition of agriculture in this country, advocate the introduction of reaping machines, but I believe the use of a scythe, instead of a sickle, would greatly facilitate the operations; and a scythe will not be very expensive either. The system of threshing in this country is certainly very primitive. The work is performed by cattle, with their mouths muzzled, treading on the crop, and it is not done well.

The dust and other foreign matter get mixed up with the corn, and the sample is necessarily depreciated. Then again this threshing has to be done in an open *khalian*, i.e., an open yard in a field, when the crop is subject to rain and foul wind. The use of a flail, an old method of threshing in England, now fallen into disuse, would be a great improvement on the native system. A flail consists of two unequal wooden rods, and the two parts are attached by means of thongs of strong leather. The longer rod is 5 feet in length, and the shorter $2\frac{1}{2}$ to 3 feet. Both are cylindrical, with diameters $1\frac{1}{4}$ to $1\frac{1}{2}$ inch, and should be made of strong wood, so that the rods may not split. The smaller rod, when the flail is worked, should fall evenly on the threshing floor, and for this purpose it would perhaps be desirable to have the "beater" slightly tapering towards the extremity.

I have so far attempted to direct attention to a few of the agricultural implements which may with advantage be adopted by Indian cultivators, and which, certainly, are within the means of many of them. I have omitted making any suggestions regarding the most important element in the success of agricultural operations in this country, viz., irrigation.

Want of water is the main difficulty here, and any cheap mode of lifting and increasing the quantity of available water for irrigation purposes should have been pointed out. I consider, however, this subject of irrigation very important, and fit to be treated separately. I purposely reserve it for a future paper.

THE UNIVERSAL FIBRE DECORTICATOR.

THE want of a thoroughly adaptable fibre-cleaning machine has long been felt in India. Handsome rewards have, from time to time, been offered for the best decorticator, and it was only in December 1884 that the Bengal Government awarded the prize of Rs. 2,000 to Messrs. Death and Ellwood, of Leicester, for their Universal Fibre-cleaning Machine, invented by a Mr. H. C. Smith, as being the best out of nine machines tried at Calcutta, under the management of two gentlemen appointed by the Government of India to carry out the experiments with these machines. When this award was made, it was thought that perfection had been reached as far as it was possible to attain that distinction, and it was confidently expected that Messrs. Death and Ellwood's machine would hold the foremost place among decorticators. But the New Orleans World's Exposition has taxed the inventive genius of the American nation, and there is every reason to believe that a powerful rival to Death and Ellwood's invention has been on exhibition at the New Orleans Exposition. The American papers are full of descriptions of this machine, which are so flattering to its general usefulness and adaptability that we have from time to time noticed it in these pages; but as it promises to excel all other fibre-cleaning machines, our readers will perhaps wish to know some detail about it.

Mr. Jules Juvenal, who recently lectured at the New Orleans Exposition on ramie, or rhea, describes this machine, which is called the Universal Fibre Decorticator, as consisting essentially of three pairs of rolls and a pair of endless aprons. The machines are of two styles. One is designed so as to enable the feeder to deliver the stalks. The other requires a workman at the rear end of the machine to take the cleaned fibre, the feeder being constantly employed in supplying the machine with material. In the first style the front rolls are smooth: the second are fluted, running about seventeen revolutions per minute. The third pair are armed with scraping blades, rigidly fixed to their periphery and winding spirally around the rolls. These rolls are also hollow, with perforations through their shell, through which water is allowed to flow for the purpose of keeping the blades clean from gum; also to wash the fibre, running 300 revolutions per minute. The material is placed on the table, and is passed half-way or more into the machine, then run back on the table, reversed, and the other end cleaned in the same manner. The second style of machine has scraping rolls in place of the smooth rolls, as in the first style. These rolls perform the office of feeding rolls, and also of cleaning the passing ends of the material by reversing the pairs of rolls, instead of the material being operated on.

This gentleman does not pay a high compliment to the experiments conducted at Calcutta under the auspices of the Government of India in 1884, which awarded the prize of Rs. 2,000 to Death and Ellwood for their Fibre-cleaning machine; nor does he hold this machine in very high estimation. He says:—

The competition at Calcutta, made under impossible conditions, retarded the invention of a practical machine; for, besides the difficulties presented by distance and the absence of material for experiment, the European mechanician was asked to produce machinery which could accomplish the delicate and tedious hand labor of the Chinese workmen, who made a pound of ramie a day by scraping with a wooden knife a part of the gummy and resinous matters. If experiments had been made in London instead of Calcutta on green stalks coming from Jersey, the absurdity would have been quickly ascertained of asking for practical machinery more than the mere separation of the fibre, which in the green state is easily accomplished, leaving for chemical agents the task of eliminating the gummy and resinous matter (adhering to the bark. There lies the whole secret. If all inventors of decorticator machines some of whom are very clever, have heretofore failed, it is because they have aimed at filling the conditions imposed for the Calcutta competition; that is, to make a machine capable of producing directly the China grass. This, nevertheless, came near being accomplished last year at Calcutta; but with what paltry results! The Smith machine, of London, which obtained a prize of 2,000 rupees, or £1,000 (£200 ?) produces, with two men and a three-horse power, sixty pounds a day.

Under such conditions ramie would be twice as high as silk. What is needed is a combination by which production, cleaning and fabrication will give a silky fibre ready for the loom at a cost from twenty to twenty five cents, about the price of first rate flax.

The *Times Democrat* has the following flattering description:—

The exhibition of the Universal Fibre Decorticator, T. Albee Smith's patent, in the Machinery Annex in the presence of a large and essentially practical audience, was an event in Exposition history to be remembered as affording ocular demonstration of the merits of a machine, which, if all signs do not fail, is destined to become an important factor in the utilization of fibrous plants. Among those present were noticed the commissioners from Japan, China, Mexico and various States of the Union, together with a number of scientists, capitalists, and mechanical experts forming such a representative audience as probably never assembled at any other exhibit in the Exposition, all of whom were unanimous in their expressions of approval. Of the mechanical construction of the machine so much is already known that recapitulation is unnecessary; hence, suffice it then to state that it fully justifies everything that can be said in its favor as a fibre decorticator, which, as its name signifies, is universal in its adaptability to the purposes for which it was created. The most noticeable points of superiority of this machine were manifested in yesterday's illustrations of its method of handling and quantity and quality of the product in hemp, flax and green ramie.

In working hemp and flax the cleaning mechanism was observed to be less severe than the processes hitherto employed, and as the

successful results there was less waste or loss. Another special feature, peculiar only to this machine in working dry material, was the forcing of air into the cylinders and against the fibre on both sides at the same time, thus absolutely freeing it from woody substances, dirt or dust, and bringing out the product perfectly clean. With green ramie, grown in New Orleans, the results were equally satisfactory. The ramie, just as taken from the field, leaves and all, was fed to the machine, and came out sans everything, but the pure fibre. Dry ramie stalks were also most favorably handled, though for best results and economy it should be worked in a green state. This fact became more evident when examples of the machine's operations were made with jute stalks of last year's growth. While the product was the same in point of perfect decortication as if the jute was green, the fibre was discolored by the drying of the bark. As farther argument of the universal application of the machine to all fibrous plants, examples were given with banana and sisal hemp, in both instances forcing conviction of Mr. Smith's claims to having with his machine successfully overcome the greatest obstacle which has hitherto beset the way of a great money-producing industry—ramie and jute culture in the South. Mr. Smith's machine is on exhibition in the Machinery Annex, and to those who desire to study it, Mr. Smith is happy at any time to show its operations.

A correspondent, writing to the *Baltimore Manufacturers' Record*, says that "the Universal Fibre Decorticator is operating on banana, sisal hemp, cane, silk grass, hemp, or any other fibrous plants available. It is claimed that it is the only machine on exhibition that undertakes to handle green plants. A guarantee is given that it will prepare any of the fibres commonly known in commerce (except cotton and silk,) making a superior product, and at less cost than any machine ever offered for sale, and the manufacturers enter it for competition against any machine manufactured anywhere at home or abroad. The exhibit is under the charge of Mr. T. Albee Smith, who will be glad to show it to any one who desires to witness its operations."

With such testimony, we can only conclude that this machine is destined to supersede all others in the cleaning of fibres. It is a curious coincidence that the inventors of both, Deane and Ellwood's and this machine, should be named Smith. There is some fear of a confusion of identity unless care is taken to avoid mistakes.

It will be observed from the quotations we have made that the Universal Decorticator cleanses green fibre, and the most extensive experiments were tried with ramie in its green state. It is perhaps superfluous to observe that the ramie of America is identical with the rhea of India. Its scientific name is *Boehmeria nivea*, and is known also by the name of the China grass-cloth nettle. It is very extensively cultivated in the N.-W. Provinces and the Punjab, where it thrives to perfection. It has attracted a great deal of attention of late years, and the only drawback to its cultivation on an extensive scale for commercial purposes, was the want of a machine that would decorticate its fibre in the green state thoroughly. It is claimed for rhea that its fibre resembles, in texture and strength, silk more closely than any other fibre, and is most valuable for all purposes. Now that a machine has been invented that answers every want, our Indian capitalists should lose no time in procuring the Universal Fibre Decorticator. It is manufactured by the Ramington Agricultural Company, Missouri, U.S.A., and application should be made to Major F. F. Hilder, agent for that Company, at his office which is situated at No. 99, Poydras-street, New Orleans. We would, at the same time, recommend some of our enterprising firms to interest themselves in the establishment of an agency in India for this Fibre machine, as it is certain to take a prominent place at no very distant date.

RAMIE, OR RHEA.

The plant, known as ramie in Europe and America, is the same as our rhea, and belongs to the nettle order, *Urticaceae*, and is known to botanists as *Boehmeria nivea*. There are other varieties of this genus, but all are remarkable for the valuable fibre they yield. The ramie has formed the subject of much writing; and although a great deal is known about it, anything that will add to our knowledge of the plant and its value as a commercial product cannot fail to be of interest. We thus

find that Mr. Jules Juvenal has been lecturing at great length on this subject at New Orleans while the Exposition there has been in full swing. We reproduce below that portion of his lecture which relates to the plant, omitting all mention of the machinery for decortivating the fibre, an account of which will be found elsewhere. We shall simply preface Mr. Juvenal's speech by the following remarks which should be borne in mind when perusing the lecture:—The ramie or rhea grows to perfection in India. It thrives in nearly every part of India, but best in the N.-W. Provinces. There are extensive plantations of it at Saharunpore in the N.-W. Provinces, and in many places in Bengal. It is usually propagated by division of roots, but equally well by cuttings. In both methods the plantings are made in February; but in some parts, in May and June. It is a hardy perennial, and once planted, will last, if not for a hundred years, at least quite as long as any ordinary individual could wish it to. In India it has been known to yield as many as four crops in one year. It delights in rich black clayey loam, intermixed with river sand, but thrives almost in any soil. And now let us hear what Mr. Juvenal has to say. He begins as follows:—

The industry of textiles is the foremost of all industries. It is that which all over the world gives employment to the greatest number of laborers, brokers, merchants, and manufacturers. The consumption of its product is diurnal and within limit. The world has ever been looking for new textiles, but particularly so since the past fifty years, which have brought about a general increase of population and modern improvements in the fabrication of textiles. The attention of the manufacturing world has during the last few years principally been called to ramie, or China grass.

What is ramie?

It was formerly placed by botanists in the class of urtica, or ortia, but it is now called boehmeria, or spearless nettle. I will call it by no scientific name. I will simply name it the richest of all plants, for it possesses wealth of growth, wealth of development, and wealth of fibre. In ordinary light ground, with a little watering now and then, no plant will grow as rapidly, no root will multiply quicker, and produce more stalks, no vegetable fibre is handsomer, richer, or more silky, than ramie. Notwithstanding all these elements of success, the Chinese alone have for a thousand years past extensively cultivated the ramie plant. How comes the civilized world to be thus backward in introducing a plant of such excellent return, and known in Europe since the beginning of the present century? For my lecture to-day, I will endeavor to inform you concerning—

1. The causes which have delayed the cultivation of ramie in Europe and America.
2. The best methods for its cultivation and production.
3. The chemical treatment of ramie and of all textile plants.

The chemical treatment is the complement of all decortivating machinery, for it takes away by dissolution all gummy and resinous matters adherent to the fibre, which no machinery can completely eradicate. I will tell you how this can be accomplished chemically, not only with no injury to the fibre, but with the result, on the contrary, of adding to its silky qualities. This perfected chemical process is the property of our firm, the Ramie Fibre Manufacturing Company, of New York, of which I have the honor of being director. It is by applying this disintegrating process to the ramie fibre, which offers the most resistance of all, and witnessing its excellent results, that, pushing forward our researches and experiments, we have succeeded in applying to all textile plants the same process at modified degrees, according to the resisting force of their various fibres. Many of these grow in abundance under your own latitudes, the pita and silk grass of Honduras (remarkably fine fibre), the common bagasse of your sugar cane, the typha, or common oat-tail, which grows abundantly in New York, New Jersey, and Sandy Hook, the bowstring hemp or Florida lily, the yucca of the Gulf coasts, the banana, the plantain, the ixie, the bear grass, the Spanish dagger, the lichegulla, the Mexican maguey, etc.

With the exception of the oat-tail, or typha, which may be monopolized by New York, all the plants which I have named can be imported in leaves—that is to say, in the crude state, free of duty, to New Orleans, which is naturally destined to become first their natural depot, and then their place of transformation into textile fibres, by the establishment of factories along your lake coast. By this means New Orleans would become the chief market of the world for textiles, and it will have been one of the results of your Exposition. I will show you later on

how this is to be effected. But let us for the present go back to ramie.

The first shipment of ramie from India to England was a lot of three bales, shipped in 1810. Experiments then showed that a ramie rope could support a weight of 252 pounds, while a Russian hemp rope, of the same size would break on the weight of over eighty-four pounds. The ramie question remained at a standstill during the time of the wars of the Empire, and the political questions which disturbed Europe during the first half of this century. It is only in 1832, and during your great war, in which the bravery, gallantry, and death-daring qualities of the Southern people attracted the admiration of Europe, that the subject of ramie industry was resumed. Experiments were made in London and in Rouen to mix cotton with ramie. Messrs. Cardier & Co., of Rouen, successfully wove a lot of Egyptian and Indian cotton, mixed half-and-half with out China grass. The warps thus obtained proved much superior to those woven out of pure cotton, but the difficulties presented by the irregularity of the Chinese market, which failed to supply a sufficient quantity of China grass, and the necessity of special looms, caused the abandonment by the fabricators of that special tissue, and cotton having resumed its normal prices was taken back as the sole agent of fabrication. In 1867 the English Government of India, believing in the future of ramie, and with the intention of introducing it into the public domain, instituted a prize of £5,000 for the best machine for decortivating in the green state.

Innumerable pamphlets and lectures on ramie, mention this circumstance as being the cause of the progress made by that textile. I am of an entirely different opinion. I think that the allurements of that prize of £5,000, though made with the best intentions, but to which were attached impracticable conditions, helped greatly to retard, by the rejection of the machines presented, the development of ramie culture. European mechanics were asked in Europe to make machinery for use in India, to work a product scarcely to be found in Europe even for purposes of study or experiment, and consequently appropriate modifications of mechanical appliances. The English Government would have done better in applying to the culture of ramie in Europe the amount of the premiums offered for the Calcutta machines. A few acres of ramie in the Island of Jersey, where a retired French Colonel cultivated it with success, would have furnished French and English mechanics all experimental material necessary to obtain a practical solution of the problem, which could have been demonstrated by competition in London.

Jute, notwithstanding its low price and easy decortication by rotting, and though imported into England since 1796, remained fifty years without being utilized to any considerable extent. It was only in 1840 that a merchant of Dundee persuaded the Holland home government to use jute bags, instead of those made out of flax, for shipments of coffee by the Government in India. A vast field was thereby opened, and jute since then has made considerable headway. The same will happen with ramie, whose fibre being so much more valuable, has been environed by nature with more obstacles to its decortication, and it is not surprising that some time and money have been lost in attempting to solve the problem. Like all great schemes, the ramie question is liable to the accusation of having enthused, crazed, and ruined a large number of its devotees. An extensive field of ramie is a beautiful thing to look at, and when at the same time one considers that the simplest kind of study demonstrates that the bark of each stalk presents an extraordinary wealth of fibre, astonishment ceases at the fervor of the adepts of this plant.

The question of machinery is now solved, and we will have as many machines as we want, so long as they are asked only to work the crude bark either green or dry. *Production should now be our only pre-occupation.* Planting should be done at once—May or June—so as to raise a crop in autumn, and I will demonstrate that a net profit of \$100 per acre can be made, during the year following the first plantation. But what climate is adapted to ramie culture? What quality of soil? How shall we plant? Where are the plants and roots? How shall we cultivate and reap? How will the crop be sold, and what certainty is there in the future of ramie?

The State of New Jersey, whose Legislature had offered a premium to ramie planters, has cultivated this plant with success, by protecting its crops with straw during winter. I would, nevertheless, advise planters in the Northern States to cultivate it only on a small scale. This is not the case in Southern States, from California, to the Carolinas, where by planting in a light soil, somewhat moist and easy of irrigation, success is certain, however extended may be the enterprise, this particularly in Louisiana, Mississippi, Alabama, Florida, Texas, New Mexico, and California. The banks of

the Mississippi, from New Orleans to Cairo, will soon, I am confident, be green with ramie, and if your leaves are not absolutely secure, it seems as if ramie had been made for such a contingency, as a sojourn of even a whole month under water does not destroy this plant. In support of this I will mention a circumstance which happened in Louisiana. Mr. Laforest, of Bayou Heron, who had a half arpent of ramie that remained two months under water, after withdrawal of the waters found the plants in good condition. Evidently there is a limit to all things, but it is well established that complete immersion for two or three weeks will not injure the ramie.

(To be continued.)

Miscellaneous Items.

A SMART shock of earthquake was felt at Srinugger, at 3-50 P. M. on the 19th June, which levelled several damaged houses.

The appointment of Special Judge of Agriculturists, at present held by Dr. Pollen, will be abolished from the 1st of August next.

News from Cashmere states that the road near Baramulla is quite impassable. Everything considered, it seems just as well that Cashmere leave is not open this year.

THE filter works constructed at Poona four years ago, at a cost of Rs. 23,000, have just been condemned by the Sanitary Commissioner, Bombay, as supplying water unfit for drinking purposes.

WE learn that Mr. T. E. Coxhead, C.S., Magistrate of Burdwan, who is at present on a tour of inspection, is now at Sahibgunge, superintending the distribution of provisions, at Government expense, to the starving population.

OWNERS of good and strong bulls suitable for ploughing purposes are sure to obtain good prices if they would send up their cattle to Bangalore, as there is a scarcity of ploughing cattle, and some ryots are paying handsome prices for bulls.

THERE is some talk of a veterinary class being established in Poona. The idea is a very good one, as in a place where so much interest is taken in horses and in their training, there should be found many willing to join a class at which they might probably learn something that would be advantageous to them in more ways than one.

It is in contemplation, we believe, to establish a regular consular agency in Yarkand. Private news from England states that the consent of China has been obtained to the presence of a permanent British Agent in that outlying dependency of the Celestial Empire; and the step is a highly necessary one, in the face of the general activity of Russia in Central Asia.

THE result of the sittings of the Mixed Committee, to settle the claims of the proprietors of the salt-pans who had entered into a contract with the British Government, has been, on the whole, favourable to the Portuguese side. The proprietors at Salsette, Bardez, and Damaun came off well, but those at Ilhas have had to submit to a reduction of 25 per cent on their claims.

AT a mass meeting of working men held at Swansea lately on evening, for the purpose of protesting against the proposed increase in taxation on beer and spirits, there was great opposition, and the motion calling on the Chancellor of the Exchequer to withdraw the proposal was negatived by a small majority. The meeting broke up in great confusion, the chairman proclaiming, amid the protest of the majority, that the motion was carried.

ACCOUNTS from planting districts in Ceylon show that the sowing and making of tea progress in a most satisfactory manner, and it is anticipated that heavy shipments of this product will be made during the remainder of our produce season. The planting out of tea goes on as briskly and as extensively as ever, and all estimates of this work for the season will be fully borne out. Every estate is busy planting tea almost entirely through the coffee, and the acreage put under the new product in this way, this season, will be enormous.

THE total number of deaths registered in the Suburbs of Calcutta during the week ending 6th June was 184, against 154 and 178 in the two preceding weeks. Under the head of cholera there were 26 deaths, against 30 and 51 in the two preceding weeks. During the week under notice there were 3 deaths from small-pox, 71 from fever, 16 from bowel complaints, 2 from injuries, and 46 from other causes. The general mortality was at the rate of 23.9 per 1,000 per annum, against 31.3 and 36.4 in the two preceding weeks; while it was 22.6 in Calcutta during the same period.

THE salt trade at Jodhpore, it is anticipated, will receive a great impetus in consequence of the completion of the line of rail, so long in course of construction, and which is now open to traffic, mainly owing to the exertions of Maharaja Pratap Singh, C.S.I., on whom the successful completion of this railway reflects the highest credit. When he first assumed office as Prime Minister, the Raj was involved in debt to the extent of forty-eight lakhs of rupees, which has not only been paid up in full, but the enormous amount of sixty-three lakhs—thanks to his financial measures—has been devoted to the construction of this line.

THE total number of deaths registered in the city of Calcutta during the week was 144 against 184 and 188 in the two preceding weeks, and 24 less than the corresponding week last year. The mortality from cholera has been unusually low during the week; 19 deaths from this cause were registered, against 18 and 27 in the two preceding weeks, the quinquennial mean being 25. There were 3 deaths from small-pox, against 3 and 4 in the two preceding weeks. Fever and bowel-complaints were somewhat below the average of the quinquennial period. The general mortality during the week was at the rate of 17.3 per 1,000 per annum.

THE oldest bank-note in existence in Europe is one preserved in the Asiatic Museum at St. Petersburg. It dates from the year 1399 B.C., and was issued by the Chinese Government. It can be proved from Chinese chronicles that as early as 2697 B.C. bank-notes were current in China under the name of "flying money." The bank-note preserved at St. Petersburg bears the name of the imperial bank, date and number of issue, signature of a mandarin, and contains even a list of the punishments inflicted for forgery of notes. This relic of 4,000 years ago is probably written for printing from wooden tablets is said to have been introduced in China only in the year 160 A.D.

WE understand Mr. Batchelor is engaged in his report for the Straits Government. Not only will it treat on the subject of the cattle-disease that played such havoc in Java and the Malay Peninsula, but there will be a *vide mecum* of the diseases that affect horses in the Straits, the method of treatment, &c. Mr. Batchelor on his visit to Europe ascertained the best method of preparing anthrax vaccine, and it was for this object the journey was taken; the difficulty of obtaining vaccine in a fresh and pure condition from Paris is no longer a matter of necessity. Anthrax vaccine is now being prepared at Ootacamund, and can be supplied direct from Mr. Batchelor's laboratory.

A PUBLIC meeting had been convened for Thursday, the 18th June, and held in the Council Chamber, Ceylon, under the presidency of his Excellency the Governor, when resolutions were proposed on the subject of the forthcoming Indian and Colonial Exhibition to be held in London in 1886. The Governor invited the public to attend, and we hope that a large number were present on the occasion. Let it be distinctly understood by all, that if Ceylon is to take part in the Exhibition she should be well represented, or not represented at all. The thing should be well done, or left entirely alone. If, as seems probable, the Government will give their utmost aid in this matter, and such a grant of money to begin with, as has already been mentioned, namely, Rs. 50,000, much may be done.

DR. BLANEY of Bombay, has addressed a thoughtful and considerate letter to a contemporary on the necessity of building health resorts for the poor Hindoos in the capital of Western India. The philanthropic doctor, who must be accepted as an authority on the subject, draws a deplorable picture of the condition of those who have certainly a claim on the good services of their more fortunate fellow-creatures. The following sentences speak for themselves:—"Nobody visits these poor in their sickness, and nobody cares for them. They lie panting, and drowsy, and helpless, in fevers, away from light and fresh air, and die when they ought to recover. If any one at all gives them help, it is neighbours who are as poor and ignorant as themselves, and, as a consequence, the help is not very useful; thus it is that the poor bear the burdens of the poor."

A TELEGRAM from a correspondent at Srinugger, dated June 24, says:—An estimate of the severity of the late earthquake, and the extent of the damage done, and loss of life, is being slowly ascertained. I have visited during the last few days the country near Baramulla. In a space of ten miles long, and eight wide, the entire country, comprising low hills and valleys, all well wooded and cultivated, is marked with fissures and landslips. Trees have been uprooted, and nearly every house has been made level with the ground. On the crest of each hill, where a village of five to ten, and sometimes fifty houses, was built of wood, in all, about eighty or ninety villages have been destroyed; in half of these, the number killed is shown to have been 500. The loss of sheep and oxen is also very great, as they are frequently placed at night in houses with the inhabitants. The loss of life throughout Cashmere cannot be under two thousand. In some of the villages, every inhabitant has been killed. Colonel Lockhart and his party arrived at Baramulla on Sunday week last, and visited Srinugger for a few days, then marched to Gilgit. The camp proceeds direct.

MANUFACTURE OF CUTOCH.

IN a letter to the Conservator of Forests, Pegu Circle, British Burma, dated 5th August, 1884, Captain Wood writes as follows:—

"I enclose an extract from the *Indian Forester* for July 1884, page 330, and beg to state that in my Circle, the season for manufacturing outch extends to only three months in the year, and that the rates levied here from catechu makers are 12 annas a pot, capable of holding about three gallons of water, or liquid substance. The rate has been raised this year from 9 to 12 annas per earthen pot, which even seems to be a very low price compared with what you get in Pegu. I should feel much obliged if you would kindly give me the following information:—

- (1). The length of the season during which outch is manufactured in your Circle.
- (2). The out-turn per season, per cauldron of 20 gallons.
- (3). The process of manufacturing as conducted in Pegu.
- (4). The price per maund of catechu on the spot.
- (5). The distance of the market from the forests where the outch is sold to retail dealers and others.
- (6). What percentage of outch is obtained from a maund of heart-wood?

The Conservator of Forests, Pegu, replied as follows, on the 5th September, 1884:—

1. "Catch is manufactured in this Circle from 1st June to 31st March; but the months from December to March (inclusive) are those in which the manufacture is most energetically carried on. In April and May, and in the drier parts in March even, scarcity of water stops the work; while in the rainy season carts cannot ply, and boilers have difficulties in provisioning themselves and disposing of their outch.

2. "The out-turn of a cauldron per season depends on such a variety of circumstances—the duration of the season, the quality of the trees, their proximity to the boiling place, and above all, the working days of the party—that an average cannot be struck. It may be 2,000 lbs. only, or it may reach, and even exceed, 8,000 lbs. for a cauldron of 20 gallons (those in use have a capacity of 12 gallons)."

3. Mr. Carter, Deputy Conservator, Tharrawaddy, well describes the process of manufacture as follows:—

"For the working of one cauldron, three men are necessary; but if a larger number of cauldrons are employed, there is some saving in labour. Of the three men, one man is employed in felling the trees, and dragging them, by means of cattle, to the outch-boiling place. The second clears the logs of sap-wood, and cuts the heart-wood into chips. The third attends to the fires and the boiling process. The chips are put into earthen pots, which are filled with as many chips as they will contain; then water is poured in until the pots are nearly full. The pots (which have a capacity of about 3 gallons) are then placed on the fire and boiled for about 12 hours, in which time the water is reduced to about one-half the original quantity. For one cauldron, 30 to 25 of these earthen pots are employed. The cauldron is nearly filled from these pots, and when the extract in the cauldron is reduced to about one-half, the cauldron is again filled from the pots, and this is repeated until the pots are emptied. The boiling process is generally accelerated by the employment of a large earthen pot which is set up near the cauldron, and is filled at the same time as the cauldron and kept boiling, the extract from the small pots being constantly added as that in the larger pot is reduced. The cauldron is then filled from the large pot instead of from the small ones. The Burmans call this large pot the *Yen-o*, or red water pot. The extract from the pots having all found its way into the cauldron, the boiling is continued, and the liquid is stirred until it attains the consistency of syrup and fills only about one-fifth of the cauldron. The cauldron is then removed from the fire and stirred with a piece of wood, shaped like a paddle, for four hours or more, by which time the mass has obtained a greater consistency, and is cool enough to be handled. It is then placed in a mould, like a brick mould, and is left to cool. This generally happens at night, and by next morning the result is a brick-like mass of outch weighing 36 to 44 lbs."

The stirring business, which takes place after the cauldron is removed from the fire, is more of a heating up, and I have never been able to ascertain what the object or effect of the process is.

Cooks differ too in the amount of heating up that is desirable, some being satisfied with half-an-hour's application. The out-turn of one cauldron of 12 gallons, in 24 hours when properly worked, is fairly constant at the figure given by Mr. Carter.

4. Cutch was worth last year Rs. 4.78 to Rs. 5.58 per maund (equivalent Rs. 15, Rs. 20, and Rs. 25 per 100 viss) on the edge of the forests, according to the distance from the Irrawaddy river or the Railway.

5. The above rates correspond to some 40, 25, and 15 miles from the markets on the railway and river, where the price was Rs. 30 per 100 viss (366 lbs.), or Rs. 6.58 per maund.

6. Regarding the amount of cutch yielded by heartwood, no reliable data are available. The yield has been stated at from 3 to 10 per cent in weight.

For practical purposes, I believe a ton of timber in the round may be taken to yield 250 to 300 lbs. of cutch."

The following note from Captain Wood closes the correspondence:—

"It appears that in Pegu the cauldron is used for the final concentration, and the price is regulated by it. 20 to 25 pots of the size used in Oudh are used to supply the 12 gallon concentrating cauldron, so that the prices levied are much the same in both provinces, as will be seen by the figures given below:—

Pegu.—Price for 4 months' working 12 gallons cauldron, i.e., 20 to 25, say 22½, 3 gallon pots =	20	0	0
22½ pots, at 12 annas =	16	14	0
Add ½ more for the 4th month =	5	10	0
				22	8	0

—Indian Forester.]

DESTRUCTION OF TREES IN THE PUNJAB.

THE destruction of trees and undergrowth on hill-sides is causing trouble in other parts of India besides the Punjab. One of these places found is in the hill tracts of the Chota Nagpore Division of Bengal, which were visited by the Inspector-General of Forests last winter. In his report, Dr. Schlich states that the floods of the Damodar river, which of late years have done much damage in Burdwan, are largely due to the clearance of forests in the upper catchment basin, much as the floods which afflicted the Hooghly and Jullundhur districts some years ago were due to the destruction of forest growth on the Siwaliks. The state of things is more serious perhaps in Chota Nagpore than is usually the case elsewhere in India, as attempts have been made for some years past to induce the people to form reserves of their own, and to refrain from their evil treatment of forest areas; and these attempts have so far proved a complete failure. Dr. Schlich proposes that the people should now be urged to apply to Government to manage their forest lands for them; and if this cannot be done, areas of waste land should be leased by Government from the people; and that, if this again is impracticable, Government should buy up waste areas. The first proposal is not likely to bear much fruit, as far as the Forest Department is concerned. If there ever was a case of *timeo Danaos et dona ferentes*, it is, whether rightly or wrongly, the case of the people of India and their Forest Officers. Leases are perhaps possible, but it is difficult to secure them without the exercise of much official pressure. For the purchase of lands on the other hand, money is seldom forthcoming; although the Forest Department might fairly claim to have a percentage of its nett annual earnings put aside to enable it to lease and buy lands as opportunity offers. The whole question is one beset with thorny difficulties. On the one hand, it is most necessary to restrain the people from their present wasteful practices, and to prevent their squandering a property which belongs in some sense to the public, and in a distinct sense to future generations of the owners of the land on which the forests stand. On the other hand, the customary rights of the people have grown so strong, that to attempt to put an end to them, is apt to shake the village constitution and faith to its very foundations. The question, however, requires to be considered from a broad point of view, in order that distinct principles may be laid down, once for all, for the clear guidance of officers with regard to it. There is no matter upon which opinions differ so widely at present, or on which views are so apt to change violently according to the personal ideas of an individual officer. We believe it is

the intention of the Punjab Government to reserve large areas for the formation of plantations in the west of the province as the colonisation of that country proceeds. And if the development of trees and canals in those tracts should prove successful in increasing the rainfall, the great-grandsons of the present generation may see areas, which are now absolutely wastes, become one of the principal sources of the timber supply of the Province.—*Civil and Military Gazette.*

ART INDUSTRY IN INDIA.

TO THE EDITOR OF THE "BOMBAY GAZETTE."

SIR,—I was much interested in reading, in your issue of the 18th instant, the account of a Hindoo student who had recently returned from America after acquiring the art of glass-making.

I entirely agree in thinking that it is of the utmost importance to promote art industries in India. About a year ago, when reviewing the progress of the Cutch School of Art, I observed as follows:—

"A sound, scientific, and technical education is the crying want of India, and Cutch is no exception. When we review the history of most of the western nations, which now occupy a prominent place in the scale of civilisation, we cannot but feel that it is their excellence in science and art which has greatly contributed to make them what they are. There was a time when India held a high place among the nations of the world, and her arts and manufactures were considerably admired. Subsequently, amidst the vicissitudes which the Aryan civilisation passed through, the decline of her industrial arts was a necessary result of the decay brought on by time.

"A resuscitation and improvement of India's dying industries, and the full development of her abundant resources, is a consummation which is looked forward to by every patriotic native of India, under the benign sway of her most gracious Majesty the Queen-Empress; and as a means to this much desired end, it is of the utmost importance to foster a taste for technical education. We have, I think, enough of mere clerks and accountants. I can say from my experience that a petty vacancy in a public office attracts up a great number of applicants; but when you want a superior artisan or other professional man you have to wait for some time before you find one who fully meets with your approval. This, then, is a want which, while giving every possible encouragement to primary education, has also to be supplied by establishing schools of art and industries in different parts of the country, and enabling promising youths to proceed to advanced foreign countries, and be trained in some useful arts and manufactures. This question is so intimately connected with the regeneration of India that it has deservedly attracted the attention of the thinking portion of the Indian public and the enlightened British statesmen of the day.

"The example set by China and Japan in annually sending out youths to Europe and America for being trained up in the useful arts and manufactures of the West, no doubt, deserves imitation."

I believe the necessity for a measure like this is generally recognized, and I am glad the attention of certain leading Maratha gentlemen has already been directed to so useful an object.

On the occasion of his installation last November, H. H. Maharaja Maharao Shri Khengarji Sawal Bahadur, who has established a scholarship of Rs. 200 a month for a student who would go to Europe or America for acquiring such liberal or technical education as might from time to time be decided upon by the State. For this scholarship no less than 22 applications were received from different parts of India—(9 Bombay Presidency, 5 North-Western Provinces, 4 Bengal, 3 Rajputana, 1 Punjab)—a circumstance which deserves prominent mention, as it serves to show that there are people willing to proceed to foreign countries for higher culture, if means be provided for enabling them to do so.

The question then stands thus: There is the necessity for sending Indian youths to Europe or America for being trained. There are youths willing and competent to be so sent, but pecuniary help is not available.

Cannot the exertions of the intelligent leaders of Indian society supply so pressing a want? If united action on the part of the people in different parts in this country is not practicable, the Presidency of Bombay may well set an example by putting forth exertions within its own limits. There are several rich and important native Chiefs who may liberally come forward to establish one or more scholarships each; others may subscribe to a common fund

to which rich private individuals may also open their purses. In this way means may perhaps be found for establishing at least a few scholarships, the affairs in connection with which being managed by a committee elected by subscribers themselves.

I am so fully impressed with the necessity of a measure like this, that I have ventured to ask for a corner of your valued paper for this communication.—Yours, &c.,

MANIDHAI JASDHAI,
Dewan of Oudh.

Cutch, Bhuj, June 19.

THE POPPY IN PERSIA.

From time immemorial opium has been grown in Persia in the neighbourhood of Yezd, and enough was also produced there to supply the demands of the native market. Nine out of ten of the aged in Persia take from one to five grains of the drug daily: it is largely used by the native physicians, and a considerable export was kept up *via* Meshed to Central Asia; the crop was considerable. During the cotton famine caused by the American war, the attention of the Persian ryot was turned to the cultivation of the cotton-bush; but Persian cotton soon became hardly worth growing save the small amount required for home manufacture, and the villages throughout the centre and south gradually turned their attention to the growth of the poppy. Year by year this crop has become a more favourite one; and the result has been that grain-growing has been much neglected, with the effect of raising the price in some districts. In the neighbourhood of Isfahan, as far as the eye can reach, nothing but fields of poppies are to be seen with a small patch here and there of wheat or barley, which the cultivator produces for his own use or to give some rest to his land. The white variety of the poppy is the one that is grown. It is sown broadcast and very thickly, and when it first comes up resembles a very abundant crop of dandelions. This redundancy is soon reduced by the ryot, who with a short curved knife hacks away superfluous plants till those that are left stand some six inches from each other. This reducing process has to be gone through many times and the ground kept clear of weed until the plant is six inches high. The fields are also irrigated once a week until the buds are about to burst into bloom. It is this irrigation probably that accounts for the inferiority of the percentage of morphia in Persian opium. And, now that the poppies are in flower and the petals are about to fall, the ryots, under the direction of men from the neighbourhood of Yezd, who travel all over Persia to superintend the gathering of the crop and its subsequent preparation, begin to collect the opium from this plant. This is done by scoring the seed-vessels with a small three-bladed knife, which makes three gashes an eighth of an inch apart and three-quarters of an inch long. The operation is performed in the afternoon. From these gashes the opium exudes in tears, which are collected at early dawn by scraping with a piece of glass or a knife. If, unfortunately, a heavy shower of rain should fall a large proportion of, or even all, the opium may be lost. This operation is repeated a second and even a third time. The poppies, after the opium is extracted, are used as fodder. The ryot often has advanced (at heavy interest) a mule to him upon his crop, and at times the speculator is rarely bitten.

In the old days, when opium was purchased by rule of thumb, and passed through several hands before it reached the manufacturer, the fresh opium was much adulterated: and it was this adulteration that gave the Persian opium the bad name it so long retained in the English market. But an enterprising English firm sent one of its partners to Isfahan, and that energetic gentleman succeeded in making the Persians understand that honesty is the best policy. The brand of the firm he represented was a guarantee of the purity of the manufactured article, and as the imports of the firm to this country were always of exactly the same standard as the sample that preceded them, Persian opium of their brand became a regular and saleable commodity. Already Persian opium has driven that of Turkey out of the great market of China; but the quantity of morphia contained in it is far less than that of the drug grown in India. Lately the average price of Persian opium has been 16s. a pound in London wholesale. Of course the Armenian middleman continues to adulterate the drug; but he hardly finds a profit in doing so, and his wares seldom leave the country.

When the first supplies of the drug begin to arrive at the "godowns" of the merchant, they come in a semi-fluid mass, generally

in a state of fermentation, giving out the characteristic smell of the drug, and therewith an odour resembling that of rotten apples. The opium is generally brought in copper pots and earthen jars—usually they are cooking utensils impressed into the service. As the opium arrives it is poured into copper pans, some of which will hold as much as five cwt. Workmen are engaged at so much a day, or in gangs who are paid so much per chest. The daily wage varies from two to five kerans (a keran being 9d.) The liquid portion of the opium is boiled down and returned to the pot; the whole is then beaten up till it is of the consistence of strawberry jam freshly made. And now begins the opium manufacture—the *terlak mali*, literally opium-rubbing. Thin planks, a yard long and a foot wide, are smeared with the paste, first longitudinally, then horizontally by means of wooden spatulas. As each plank is covered it is placed on end in the strong sun, and when sufficiently dry the opium is scraped for rolling into cakes. If the opium is very moist, or the sun very weak, this process has to be repeated. The opium is now kneaded into cakes of a pound, three drachms over being allowed for loss of weight in transit. The cakes have the shape and appearance of a large squared bun. They are varnished with some of the liquor or with a composition, and when quite dry are stamped with the maker's name. And now each cake is wrapped in paper, and laid in cases made as strong and light as possible, as the duty is levied at per case. The cases are sewn up in raw hides, or dammed—i. e., packed in tarpaulin.

It does not appear that the moderate use of Persian opium in the country itself is deleterious. Opium-smoking is almost unknown; and opium when smoked is, as a rule, smoked by a native doctor's prescription. The opium pill-box, a tiny box of silver, is as common in Persia as the snuff-box was once with us. Most men of forty among the upper and middle classes use it. They take from a grain to a grain and a-half, divided into two pills, one in the afternoon and one at night. Travellers, too, almost invariably take it.

In 1871 the value of the export of opium from Persia was 696,000 rupees. In 1881 it had increased to 8,470,000 rupees, and the increase has been steady each year. Probably this increase will continue, and ultimately Indian opium will find a rival, and our revenue in India will be thus much reduced. For the Chinese market, a certain portion of oil is used in the preparation of Persian opium. The preparation of the opium for market is a very anxious time with the merchant. He has to be constantly in and out, and is obliged to pay watchers, and pay them well, to keep pilferers from his goods. The labourers engaged in the *terlak-mali* are searched on leaving, as a matter of course; but they generally manage to add considerably to their wages by what they can purloin. This is their "cabbage," or *modakel*—a word much in use in Persia, where as a rule a man's pay is often much less than his *modakel*. A man's pay is usually known, and, on common questions, Persians are "What is his pay?" and "What is his *modakel*?" A servant's *modakel* is what he can take from the tradespeople, generally ten per cent. a governor's *modakel* is what he can exact from the taxpayer over and above the taxes; the Shah's *modakel* is what he can sell the governorships for; and so on.

The manufacture of opium is rude in the extreme, and opportunities for speculation many. It has been suggested to rub the opium on a hot plate with a chocolate-making machine, but no one has tried it. Were it not for the opium-growing the king's ryots would find it hard to pay their taxes. But the indiscriminate cultivation of this valuable crop to the exclusion of cereals tends to render bread and horse-feed dearer; and if the cultivation of the poppy continues to spread as it has done during the last twenty years, Persia will cease to be, what it is now, the cheapest place to live in the world.—*Planters' Gazette (English Paper)*.

WHAT IS THIS DISEASE THAT IS COMING UPON US?

LIKE a thief at night it steals in upon us unawares. Many persons have pains about the chest and sides, and sometimes in the back. They feel dull and sleepy; the mouth has a bad taste, especially in the morning. A sort of sticky slime collects about the teeth. The appetite is poor. There is a feeling like a heavy load on the stomach; sometimes a faint all-gone sensation at the pit of the stomach which food does not satisfy. The eyes are sunken, the hands and feet become cold and feel clammy. After a while a cough sets in at first dry, but after a few months it is attended with a greenish coloured expectoration. The afflicted one feels tired all the while, and sleep does not seem to afford any rest. After a time he becomes nervous, irritable, and gloomy,

THE INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA :—SATURDAY, JULY 11, 1885.

[No. 28.]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING JULY 1, 1885.]

General Remarks.—Heavy rain has fallen in Malabar and Travancore, and slight rain elsewhere in the Madras Presidency. Prospects have slightly improved in Bellary and Anantapore, and are generally fair. In Mysore rain has been general, except in Tumkoor, where more is wanted. Prospects in the province are fair. There has been heavy rain in Coorg, where prospects are good.

Several districts in the Bombay Presidency report good rain, but more is urgently wanted for sowings in most places. *Kharif* preparations continue in several districts. In the Berars and Hyderabad some rain has fallen. Rain has also fallen throughout the Central India and Rajpootana States. In the latter, *kharif* ploughing and sowing are reported to have commenced.

Rain is reported from most districts in the Punjab, and from all parts of the North-Western Provinces and Oudh. *Kharif* operations are in active progress in both provinces. In the Central Provinces good rain has fallen everywhere, except in Nimar, where more is wanted. Sowings for the *kharif* are in general progress.

Good rain has fallen throughout the Lower Provinces, except in parts of the Patna Division, where the fall has not been quite sufficient. Prospects are now generally favourable, except in Tipperah, where excessive rain and floods have caused much damage. Standing crops are doing well, and agricultural operations are progressing favourably. In Upper Assam more rain is wanted. Standing crops are doing well. Preparations for the *sali* crop are in progress. Tea is doing well in Cachar, but is backward in Dibrugarh.

In British Borneo ploughing and sowing have commenced in a few districts, but excessive rain has interfered with agriculture in Tavy.

The public health is generally fair in most provinces; and prices are, on the whole, stationary.

Madras.—General prospects fair slightly improved in Bellary and Anantapore.

Bombay.—Good rain in several districts, but more required urgently for sowing in most places; preparations for *kharif* crops continue in several districts. Scarcity of drinking-water in two talukas of Dharwar and one of Belgaum, and of fodder in four talukas of Dharwar, one of Ahmednugger, one of Belgaum, and parts of Khandesh. Cholera generally prevalent, small-pox in parts of twelve, and fever and cattle-disease in parts of seven districts.

Bengal.—There has been general rain throughout the province again this week; in a few places only in the Patna division the rainfall is said to be not yet quite sufficient. Prospects are now generally reported to be favourable, except in Tipperah, where considerable damage has been done by excessive rain and floods; early rice, jute, sugar-cane, and other standing crops are now growing well, and cultivation of late rice is in full swing all round; in some places transplanting of *aman* seedlings has begun. Public health is generally fair, though cholera is still prevalent in some localities.

N.W. Provinces and Oudh.—Good rain has fallen throughout the provinces, doing much good. *Kharif* operations in progress everywhere. Markets are well supplied and prices generally steady. Public health fair.

Punjab.—Rainfall almost general. Health good. *Kharif* ploughings and sowings in progress. Prices stationary.

Central Provinces.—Rain favourable everywhere, except in Nimar, where it is insufficient. Sowings progressing. Cholera continues in Chutlagurh. Prices steady.

British Borneo.—Cholera slight in Akyab, Sandoway, Thongwa, and Shwegyin. Small-pox slight in Honzada, Kyonkpyon, and Tharrawaddy; elsewhere public health good. Cattle-disease slight in Honzada, Prome, and Thongwa; severe in Ancherat; elsewhere health of cattle good. Rainfall seasonable.

Assam.—Weather warm. Ploughing and sowing of *damai* and *murali* crops not altogether finished. Common rice 10½ seers per rupee. Tea doing well. Four deaths from cholera reported from Hailakandi; general health good.

Mysore and Coorg.—Transplanting of paddy commenced. Prospects of season and public health good.

Berar and Hyderabad.—*Kharif* sowings progressing; fodder and water obtainable everywhere. Tanks have received no water yet. General health good. Prices—wheat 14½, coarse rice 12½, white *pari* 19½, yellow *ju ri* 23½, and *tar* 17 seers per current *ajee* rupees.

Central India States.—Health and prospects good. Weather seasonable.

Rajpootana.—Sowing commenced. Tanks and wells filling. Fever prevailing; health otherwise good. Prices stationary. Weather very hot, with high wind.

Nepal.—Transplanting of rice commenced. Cholera continues.

Letters to the Editor.

TESTS FOR TIMBER.

TO THE EDITOR.

SIR,—The following may be of use to TIMBER MERCHANT with reference to his enquiry in your issue of the 27th June :—

Cut the wood transversely, and apply a solution of iodine; if the iodine turns into a deep violet, it is a test,—

- (1) That there is starch, which is a sign that the wood is good.
- (2) That it was felled in winter.

But if the solution be colorless, it proves that there is sap, which denotes that the wood was felled in summer.

W. B. G.

Allahabad, July 4, 1885.

COCOANUT BORERS.

I.

TO THE EDITOR.

SIR,—Will you or any of your readers kindly suggest a remedy for the destruction of cocoanut borers? Many of the agriculturists of Southern India will be under great obligation to Baboo Hem Chander Dutt if he can give the vernacular names for "cownut-borer."

AN ENQUIRER.

Soolakera Estate, Mysore Province, June 21, 1885.

* NOTE.—For an answer to this query, we would refer the correspondent to the *Indian Agriculturist* of the 16th May 1885, page 251. Ed., L. J.

II.

TO THE EDITOR.

SIR,—In reply to your correspondent AN ENQUIRER, I would suggest the following methods for the destruction of cocoanut borers :—

1. If the fruits are attacked while on the tree, take equal parts of fresh lime or chunam and salt, well mixed together, and sprinkle on the ground round the roots of the trees, taking care to loosen the soil for a couple of inches previous to applying the mixture. Having done this, water regularly for three days, and then manure the tree by throwing round its roots 2 or 3 baskets full of coal-ashes.

2. If the borers injure seedlings, then take some fresh lime and mix it with water; then sprinkle the lime in its quick state upon the land that is over-run with this pest, at the rate of 10 gallons per bigha. The lime should be sprinkled towards the wind, as, falling upon them in a heated state, will instantly drive out borers, &c., &c., vermin, insects, &c.

3. If the borers injure or damage cocoanuts kept in stacks in barns, then put a large quantity of wild-vine or hedge plants upon the stacks. The offensive smell of this plant is a certain remedy for borers. It may be added that if a handful of rice by any chance gets mixed with the cocoanuts kept in stacks, they will all be damaged.

HEM CHUNDR DUTTA.

Rugheo Nath Chatterjee's street,
Malaker's Cottage, July 4, 1885.

MITES, &c., IN RICE.

I.

TO THE EDITOR.

SIR,—I am thankful to your able correspondent, Baboo Hem Chundra Dutta, for the recipe he recommended for the destruction of rank grass, weeds, &c., &c., and fertilizing soil so that it may become sharp, porous and friable. It is needless to say that his method proved successful, and I believe that if any one, like myself, tried Baboo Hem Chundra's method, he would concur with me.

Having been benefited thus by you, I take the liberty of asking you another important question, and hope that either you, or any of your numerous correspondents, will kindly enlighten me on the subject. Lately I stacked a quantity of rice in my small barn, and took every precaution to secure it from the attacks of mites, mice, &c., but to my misfortune, within four months most part of my rice was destroyed by these pests. What should I do to guard against these pests?

ANOTHER FLORIST.

Calcutta, July 6, 1885.

II.

TO THE EDITOR.

SIR,—I would recommend ANOTHER FLORIST to adopt the following simple method to keep his rice barn free from the ravages of the pests he complains of, and would be glad to know the result through the medium of your valuable paper:—Mix the rice, either *attur* or *seedho*, with a small quantity of dry *chunum* before storing it in the barn, and round the base of the stack sprinkle fine, white, dry sand (proportionately according to the quantity of rice) before the thatch is put on. This will, I think, secure rice from the depredations of rats, mites, weevils, &c., for more than 6 years without the least alteration, either by humidity or fermentation.

HEM CHUNDR DUTTA.

Calcutta, July 7, 1885.

Editorial Notes.

We invite attention to a paper bearing the title of *The Opium Traffic*, which will be found elsewhere. It is an important subject, and has been fully dealt with.

In the first two months of the current financial year, the Assay value of coins and bullion received in the Indian Mint, has been Rs. 2,30,95,578, and of those coined and examined Rs. 2,18,98,237. Of this latter sum, the Calcutta Mint coined Rs. 76,42,667, and the Bombay Mint, Rs. 1,42,55,580.

The little Deoghur Railway shews rapid progress. The traffic of the last half-year compares with that of the corresponding six months in 1884, as follows:—

	1884.	1885.
Passengers	77,380	104,803

The goods traffic by the line is trifling in amount, as it is essentially a passenger line. The total receipts of the last six months were Rs. 12,982, against Rs. 10,807 for the same period last year. We congratulate the shareholders, and Messrs. Burn and Co., the managers, on these results.

We print elsewhere an interesting paper on the destruction of locusts in the little Island of Cyprus. The ravages of this pest in India are too well-known to need comment. Miss

Gordon Cumming's paper shows what can be done by vigorous and determined measures, carried out thoroughly and systematically, and that it is even possible to exterminate such a plague as the locust. We commend this paper to the earnest consideration of our Indian local and district officials. We would, at the same time, suggest to the Government of India the advisability of circulating this paper far and wide, with a view to the adoption of some such measures in India.

Most people will admit that it is rather difficult to keep agricultural implements with polished surfaces free from rust, particularly during the rainy season. An American contemporary says that the following preparation applied to the surface will prevent any rusting on ploughs, or any other metal surfaces which it is desirable to keep clean, polished, and free from rust: Melt one ounce of resin in a gill of linseed oil, and while hot, mix with two quarts of kerosine oil. This can be kept on hand, and applied in a moment with a brush or rag to the metal surface of any tool that is not going to be used for a few days, thus preventing any rust, and saving much vexation when the time comes to use it again.

An effort is being made to prove that the assembly of the ryots at Jhingergacha had no real significance, and no importance. We suspect that this effort springs from some jealousy of the *Amrita Bazar Patrika*, which is supposed to have promoted the meeting, on the part of the *Sanjivani*, which claims to be the true organ of the ryots. If this is so, it is certainly very foolish. The *Sanjivani* reporters being hostile, affirm that there were but 5,000 ryots at the meeting, and that these were drawn there by the fact that the *Pagla Kanis* 'bard' was to be present, and that the ryots had no work to do on account of the *Amba bache* ceremony, whatever that may be. The statement that the meeting was instigated by the zemindars, we believe to be absolutely untrue.

The fall in the present price of silk is reported to be lower than at any time since the French Revolution of 1849. This, in a great measure, is due to the enormous imports from China during the present year; and, as a natural result, the English silk market is glutted. Some idea of this may be gathered from the fact that during the last eleven months of 1884, the imports of China Silk had reached 30,098 bales, compared with 12,789 bales in the corresponding period of 1883. The reason for this is not far to seek. The Chinese dealers and merchants were, very naturally, in great fear of damage being done to them and their goods by the French on the one side, and of internal exactions on the other; while the plunder to follow by third parties in a time of panic, urged them to prefer to sell off their stocks at low prices. The present stocks of China silk in the London markets amount to 28,000 bales, valued at nearly two millions Sterling.

A CORRESPONDENT of the *Statesman*, referring to the article on the Mango, which recently appeared in these pages, says:— "All lovers of this most delicious fruit would do well to follow the advice of the learned writer [Dr. E. Bonavia]. Mangoes, if properly and scientifically cultivated, will no doubt become a source of income to the country. But there is one very great drawback to the regular and successful cultivation of them in the districts of Backergunge, Furreedpore, Jessore, and the eastern portions of the district of the 24 Pargunnahs. A kind of insect allied to the common beetle is found in our mangoes, and makes them totally unfit for the table. It is believed that the larvæ of these insects are deposited by the mother in the unripe fruits. They are thus furnished with a shelter, and food for their support, and when fully developed cut their prey out of the fruit. Even the best imported mangoes are liable to their ravages. Can the learned writer of the article above referred to, or any one of your numerous readers, suggest a remedy for this evil?"

One of the conclusions reached by Dr. Lazenby, director of the Ohio Experiment Station, as the result of two years' experiments

with corn, says the *Farmers' Review*, is that deep cultivation should come before planting; rather than after, and that the after culture should be more and more shallow as the corn increases in size and the roots more completely fill the soil. This fully accords with our experience and teaching. We have found deep culture late in the season (tried as an experiment) to cause the corn to so droop that it did not recover visibly from its effects for a week. The harrow is the implement for use in the corn field, from planting till six inches high. The cultivator can then be run deep, if desired, once or twice. But all subsequent cultivation should only stir the surface without mutilating the roots. This is especially true in a dry season.

**

We learn that Mr. Ozanne, Director of Agriculture, Bombay, lately reported to the Bombay Government, that "arrowroot from Bermuda seed has been grown and manufactured in the Ratnagherry District, by Mr. Narayan Ramchandra Gogate, a resident of Dapoli. He has brought me samples of the prepared arrowroot. He has shown me a certificate from Mr. D. S. Kemp, to the effect that the 'sample is the species known as Bermuda arrowroot,' and another from Dr. Anna Moreishwar Kunte, Demonstrator of Anatomy, Grant Medical College, to the same effect, but with the addition—'I am glad to find that it is equal in all respects to the best species of arrowroot available.' Mr. Gogate has been five years experimenting with the production, and has now obtained a crop of 350 lbs. of prepared arrowroot, and has put down enough land this year to produce 3,000 lbs. The best arrowroot sells in the shops from Rs. 1-4 to Rs. 1-12 per lb. Mr. Gogate is willing to sell the 200 lbs. he has now in stock at 12 annas per lb. He will undertake to supply next year 3,000 lbs. at the rate of 8 annas. He has reasonable hope of reducing the price if he can succeed in procuring better appliances for its manufacture." The Government sent a sample of the arrowroot, to the Chemical Examiner, for analysis. Dr. Lyon reports:—"I have examined the arrowroot, and find the same to be of the description known as Maranta, or West Indian arrowroot, and to be free from adulteration, and of good quality."

**

THE Lahore paper makes the following very appropriate remarks on the subject of Indian Cottons:—"Indian cottons, which are, much more than American, liable to variation, rottenness of staple, and 'fluffiness'—which means waste—are viewed with particular suspicion on 'The Flags' at Liverpool, and for this, those engaged in the trade are chiefly to blame. How can this suspicion be removed and confidence restored? To this, we would answer somewhat as follows: Avoid small consignments, and let cottons be judiciously mixed; the keeping of the resultant mixture always at a standard being the one end kept in view. If Indian shippers would combine and, instead of sending home small lots of cotton which are never liked by the English spinner, however small he may be, let them be mixed down into larger consignments of, say 1,000 bales, let them be well, but not over, ginned; let them be free from dirt and regular in quality; and let the greatest care be taken that the second shipment shall correspond, as nearly as possible, in quality and character, to the first; the third to the second, and so on; and we are convinced that in a short time the cotton shipped under this mark, whatever it may be, will always fetch its full value in the home markets—because spinners will have confidence in buying it. A word in conclusion, to Indian spinners. Realize the fact that Indian cottons are unsuited for the finer classes of goods, and if you wish for comfortable profits, spin 'Low Numbers' and manufacture 'Coarse Cloths.' Attend more to packing and mixing, and be very careful that the men who have charge of the mixings know cotton thoroughly."

**

In the districts of the Madras Presidency there were 73,337 births in November, and 69,858 in December, 1884. The deaths registered during the same period numbered 59,977 and 58,313, respectively. More than one-half the deaths occurred from cholera. In the municipalities there were 4,847 and 4,693 births during the months of November and December, respectively, and 4,749 and 6,491 deaths. Of the

sexes born, there were, during the two months for both town and country, 72,391 boys and 69,914 girls, the former exceeding the latter by 3.5 per cent, or 100 girls for every 103.5 boys. The mortality was also greater among the males, being 75,000 males to 71,290 females, or in the proportion of 105.3 of the former to 100 of the latter. The ratio of total births to population was, including districts and municipalities, 31.5 per mille, per annum, in November, and 29.9 in December. The death-rates were 25.8 and 37.4, respectively. The mortality, as compared with the ratios for Bengal, N.-W. Province, and the Punjab, for the same periods, is as follows:—

	Death-rate per mille per annum.	
	November.	December.
Bengal	27.4	26.2
Nor. W. Province	42.1	32.2
Punjab	60.0	39.6
Madras	25.8	37.4

In this respect the Madras and Bengal Presidencies compare most favourably with the N.-W. Province and the Punjab, where one would expect the mortality to be very low.

**

As curtailment of public expenditure is the order of the day, the Madras Government, in compliance with the wishes of the Supreme Government, have ordered reductions to the extent of Rs. 24,61,393. The following are the details of the reductions:—Land revenue reorganization establishments held over, 4½ lakhs; Saidapet farm closed, Rs. 7,670; Revenue Settlement Department reduction, Rs. 16,654; Survey Department reduction, Rs. 75,000; Salt, 3½ lakhs; Forest, 1 lakh; Marine Department, proposed purchase of steamer abandoned, Rs. 1,15,000; Scientific and Minor Departments, Public Exhibitions and Fairs, Rs. 16,000; Cinchona Plantations, Rs. 10,000; Protective Works, Irrigation, Godavari and Krishna Deltas and Sangam Anicut, 4 lakhs; South India Railway, Rs. 48,480; Minor Irrigation Repairs, 2 lakhs; Military Works, Rs. 2,77,006; Postal and Telegraph, Rs. 11,200; Provincial Public Works, Rs. 2,91,053; Board of Revenue, Rs. 37,000; Vizagapatnam Agency, Rs. 18,830; Churches and Cemeteries, Rs. 7,000; Army, Rs. 30,500—total, Rs. 24,61,393.

**

Our Lahore contemporary, writing on the subject of the Indian Coal supply, says:—"By no means the least important chapter in Colonel Stanton's last report, is that relating to mineral resources, more especially is it important to this Province, where the fuel question is every year literally becoming a more looming one. Wood is everywhere growing scarcer and scarcer, and as our railways extend, the provision of some practical substitute is more imperative. Anything in the shape even of the most inferior coal would be invaluable, and we are glad to notice that the further coal explorations in the Salt Range near Pind Dadun Khan, commenced last year, have yielded more favourable results than were anticipated. Eighteen out-crops gave total length of exposed coal seam ~~the~~ of two miles, the average thickness of which was reported as 15 inches. The total area of limestone which overlies the coal, is 125 square miles, and if under only a small portion of this there is coal of useable quality, and that can be got at reasonable expense, the results would no doubt be of the greatest value. Two places have been selected for further trial operations—Chittidand and Dandot. An experimental drift at the former is said to have yielded coal 30 inches thick, which promises to continue; at the latter also, a coal seam of 30 inches has been found in one drift, and experimental borings to examine the extent of the field are in progress. We must confess to being somewhat sceptical as to the results."

**

A CORRESPONDENT, writing to the *Gardener's Monthly*, cites the following curious instance of trees growing through a tombstone:—"With a friend of mine, I visited a place called Lucien, in Hertfordshire, about eighteen miles from London, to see, as was said, 'the greatest curiosity ever heard of,' situated in Lucien churchyard. There we saw seven ash and three aycamore trees growing through a tombstone out of a grave. The

stone was about twelve feet long, six inches thick, and eight feet wide. The growth of the trees had split the stone in all directions. Some of the trees at that time were seven inches through, and about fifteen feet high. The grave lot was enclosed with an iron fence twelve feet high, and the branches of the trees and some parts of the trunk had grown into the fence in all imaginable shapes and forms. Of course, there is a 'true story' connected with the circumstance, as the people of Hertfordshire will strongly affirm. The person buried in this grave was a lady of title, Lady Anne Grimstone, who was buried there somewhere about a hundred years ago. She was an unbeliever in a Supreme Being—in fact, an infidel—and those who doubt it can buy a book, sold by pedlars for six-pence, strongly confirming the horrible story in detail. This lady asseverated previous to her death, that if there be a God or devil, a heaven or hell, she hoped ash and sycamore trees might grow through her body. No one planted these trees there, and the people religiously believe that, to prove to the living the horrible heresy of the dead, the trees came from her body, and the more to attract attention, have grown up through and broken the stone."

A CORRESPONDENT writes to us privately: "Agricultural Europe is being ruined, and industrial Europe with it in a measure, through the operation of the mono-metallic fallacy. And England suffers first and most. One noticeable result of the struggle for gold is, that England cannot retain hers when other markets want it, and it requires a high Bank of England rate, higher than is warranted by trade, to turn the stream. This was very clearly demonstrated last November, when New York, where money was begging employment at 2 per cent, still could take gold, though the Bank of England rate had been advanced to 5 to check exportation. Trade of course had to suffer, and should the gold craze continue, the bank rate will require to be permanently raised to a protective level, without regard to the demands of England's own trade."

This forecast we believe to be absolutely true, and it is as unfortunate as it is remarkable, that the chief commercial nation of the world should be behind so many others, in its discernment of the state of things. The world is to-day exactly in the same position in which it was throughout the first half of the present century. Its commerce and industry are held in bonds, by the want of a sufficient medium of exchange. Prices are everywhere slowly receding as they did then, without men knowing why, and it was not until long after the discovery of the gold fields, that the cause was clearly discerned. The same evil of an unduly restricted medium of exchange has overtaken us since the year 1872-73, when the demonetization of silver by Germany, and the action of the Latin States, began greatly to intensify the evil.

THE following is the official summary of the reports of the the Revenue and Agricultural Department, on the state of the crops throughout India, for the week ending 1st July:—Heavy rain has fallen in Malabar and Travancore, and slight rain elsewhere in the Madras Presidency. Prospects have slightly improved in Bellary and Anantapore, and are generally fair. In Mysore rain has been general, except in Thunkur, where more is wanted. Prospects in the province are fair. There has been heavy rain in Coorg, where prospects are good. Several districts in the Bombay Presidency report good rain, but more is urgently wanted for sowings in most places. *Kharif* preparations continue in several districts. In the Berars and Hyderabad some rain has fallen. Rain has also fallen throughout the Central India Rajpootana States. In the latter *kharif* ploughing and sowing are reported to have commenced. Rain is reported from most districts in the Punjab, and from all parts of the North-Western Provinces and Oudh. *Kharif* operations are in active progress in both Provinces. In the Central Provinces good rain has fallen everywhere, except in Nimar, where more is wanted. Sowings for the *kharif* are in general progress. Good rain has fallen throughout the Lower Provinces, except in parts of the Patna Division, where the fall has not been quite sufficient.

Prospects are now generally favourable, except in Tipperah, where excessive rain and floods have caused much damage. Standing crops are doing well, and agricultural operations are progressing favourably. In Upper Assam more rain is wanted. Standing crops are doing well. Preparations for the *kharif* crop are in progress. Tea is doing well in Cachar, but is backward in Dibrugarh. In British Burmah ploughing and sowing have commenced in a few districts, but excessive rain has interfered with agriculture in Tavoy. The public health is generally fair in most Provinces; and prices are, on the whole, stationary.

In accordance with the orders of the Punjab Government, it has been arranged that the usual annual returns relating to manufactures, which form a portion of the annual report on the internal trade of the province, should be discontinued, and that instead, a separate report should each year be prepared of some particular manufacture. The result has been an admirable monograph on the cotton industry of the province, which has just been issued by the local Secretariat. The area of land on which cotton was cultivated in the Punjab for the last four years, was shown, in the Revenue Administration reports as follows:—

	Acres.
1879-80	777,041
1880-81	785,884
1881-82	800,087
1882-83	830,631

Referring to the cotton reports of the same years, there seem to be some discrepancies in the figures shown. This is accounted for by the exclusion in some cases, and inclusion in others, of lands which were sown with cotton, but of which the crop failed to come to maturity. After making all allowances however, it may be presumed that the average extent of land under cotton in the Punjab is somewhat over 800,000 acres, and that there is a tendency to increase. The outturn per acre of cleaned cotton was shown in the last three reports as 96lbs. and 103lbs. The total yield of the province is as follows:—

	Cwts.
1879-80	644,488
1880-81	658,917
1881-82	789,581
1882-83	804,917

giving an average of 722,724 cwts., or 1,011,815 maunds annually. The excess of exports of raw cotton from the province over imports into it from other provinces, was shown to amount on the average to about 110,000 cwts. a year or 154,000 maunds. The cotton exported is sent to Calcutta, Bombay, and Kurrachee in nearly equal quantities, and on the average about 9,000 maunds are exported to foreign countries beyond the northern and western frontiers. The average exports from the province by rail and river, from 1880-81 to 1883-84, were 137,384 maunds, and the average imports from other provinces were 22,926 maunds. It thus appears that 857,000 maunds of raw cotton, or 84 per cent of the whole yield of the province, is locally consumed.

IMMIGRATION from India to the several colonies, although it has increased of late years, has not taken a popular hold of the people. Almost in every case, the demand has very largely exceeded the supply. This fact is borne out by the Indian Immigration Report for 1883, relating to the Island of Fiji. In it we find that the demand and supply for adults during the two years, 1882 and 1883, were as follows:—

	Applied for	Supplied.
1882	1,200	901
1883	1,678	896

During the season of 1883, two ships, carrying 1,017 of all denominations, sailed from Calcutta, and of this number 992 landed at Fiji. There were 4 births and 29 deaths at sea. The mortality at sea during the past three seasons, from 1881 to 1883, ranged between 17.15, 29.19, and 17.75 per cent. The proportion of females to males of all ages was 41.34 and 40.81 in the two vessels, respectively. This is very nearly in accordance with the authorized standard of 40 females to every 100 males. The rate of mortality on plantations, amongst indentured immigrants, during 1883, was 3.16 per 100, which is very much in excess of that for the preceding year, viz., 1.93. The reason given for this is that the immigrants by the *Poonas* were less hardy or healthy, than those despatched in other vessels. This can, however, scarcely be taken as a valid reason. The fact is, that cholera broke out on board the ship, resulting in 14 deaths. There was a total of 2,349 Indian immigrants resident on the plantations during 1883. Of

these 33 had died. It is stated that the mortality amongst the coolies, serving on large alluvial flats fringing the course of rivers, was higher than amongst those situated in non-alluvial tracts. This is a curious fact, and it would be interesting to know the cause of it. It is also stated that a very general desire has been evinced by many free coolies to take up land and settle in the country, but that no facilities have as yet been offered to them for the acquirement of land. We cannot understand why these facilities have been withheld. It is obviously of advantage to encourage such a desire, as the cost to an employer of introducing an immigrant ranges between £15 and £21. A peculiar feature of the present report is, that applications for Indian immigrants were almost entirely confined to recent settlers in the colony; the earlier colonists clinging with extraordinary tenacity to labourers from Polynesia. There is no apparent reason for this, as a Polynesian immigrant costs more to import, and is more liable to sickness, than the Indian; while the cost of his return passage falls on the employer instead of on the public revenues, and his natural food, on which only he will thrive, has to be imported, and cannot be kept for any length of time. Besides this, his indenture is only for three years, and he rarely engages on the same plantation after expiration of his agreement. In fact, all the advantages are on the side of the Indian immigrant. The rainfall in Fiji is very heavy. In one place it rained 231 days in the year, in another 170 days, and a third 185 days, giving a total rain-fall in each, respectively, of 123·14, 154·91, and 76·44 inches. This to a certain extent, accounts for the low average, number of days worked by coolies. Money to the amount of £1,242 was placed in deposit by 72 immigrants in the banks at various periods. One hundred letters were despatched to India free of charge. Altogether, the report bears testimony to the general well-being of the indentured Indian immigrants throughout the colony. This question of immigration is one of considerable importance, and too much attention cannot be devoted to the comforts and interests of those who leave their native land to labour in our colonies.

MR. RIBBENTROP, the officiating Inspector-General of Forests, complains, and we think with truth, that several of the local Governments were, for some reason or other, not able to secure candidates for their forest service, of a sufficiently advanced education, to enable them to follow the forest ranger's course. To meet this difficulty, however, a vernacular class was established during the year in which a somewhat more elementary education can be acquired by students who have not a knowledge of English. The course of the Forest Rangers' class extends now over 18 months, and is arranged somewhat as follows: Theoretical instruction is given from the 1st July to the 31st October, in vegetable physiology (including the structure of wood), elements of physics and chemistry, mathematics, surveying, road-making, and building. This is followed up by a two-months' practical course in surveying, which is found sufficient to pass the students for the lower standard. From January to June the students are taught sylviculture in all its branches, in theory and practice, and in this respect the greatest progress has been made during the year by means of the (already mentioned) appointment of a special teacher. Formerly, when no special instructor was available, the students were distributed amongst selected Forest divisions for a course of training in practical sylviculture; but it was found, as might have been expected, that the officers in charge of divisions had but rarely the leisure for special instruction of students, and not often the inclination. The present arrangement, however, obviates this. In July of the second year, a purely theoretical course of instruction begins, extending up to 31st December, and includes forest working plans and utilization, systematic forest botany, elements of mineralogy, and geology, forest law, elements of etiology, and mathematics. This arrangement is the outcome of frequent discussions and consultations, and is said to be thoroughly practical and to work well. The Vernacular class extends over twelve months only. The instruction is much the same as that imparted by the English class, though of a more elementary nature, being based more on a rule of thumb, whereas the Rangers' class embraces the theory of each subject taught.

The staff of teachers employed during the year was composed wholly of able Forest officers, nine in number, each one taking

up a separate subject. Three Gazetted officers attended the school for the theoretical part of the course, from 1st July to 31st October. The second year's class was attended by nineteen students. Of these, one resigned, one was granted a Forester's certificate only, three were put back a year, and fourteen obtained a Ranger's certificate, which was granted with honors to two of them. The first year's Rangers' class was attended by only eleven Government students (one of whom has since resigned), one probationer, and seven students sent from Native States. The Foresters' class was attended by five students, all of whom belong to the North-Western Provinces. It is satisfactory to note that the number of students sent from Madras and from Native States has increased so much. Mr. Ribbentrop concludes his report with the following significant remark:—"Conservators of all provinces, who have given a somewhat more extensive trial to the education afforded at the Forest School, have expressed it as their decided opinion that the passed students of the school are, as a rule, markedly superior to their untrained compeers; and it is, therefore, all the more to be regretted that the Central Provinces, Bengal, and Assam have not sent students to Dehra, and that some of the other provinces do not make a more extensive use of the establishment." The expenses of the school amounted during the year to Rs. 22,934. The Government of India, in summing up the report, recorded the following order:—"It has been recognized as the policy of the Government in forest organization, that the forest range shall ultimately form the working unit of Forest administration; and it is necessary, therefore, in order to keep pace with the gradual expansion of the department, to provide an efficient staff for these subordinate duties. Experience has shown that rangers who have passed through a professional course of training at the school have, on return to their province, been found to possess a better knowledge of their duties than untrained men. It is matter of regret, therefore, that some provinces have not as yet sufficiently availed themselves of the advantages to be derived from the school. The Governor-General in Council trusts that local Governments will once more instruct Conservators of Forests to use their utmost endeavours to select and secure suitable candidates for training at the school. Divisional Forest officers and Deputy Commissioners, who have better opportunities of knowing the capabilities of the members of the local subordinate staff, might also, with advantage, be asked to assist Conservators in this respect."

PLOUGHS AND PLOUGHING, BURMAH.

[By Mr. F. W. Coburn, Assistant Director of Agriculture, British Burmah.]

So far as the writer of this note has been able to judge, after an experience of eight years' intimate connection with the cultivation of the soil in Bengal, North-Western Provinces, and British Burmah, the failure to introduce successfully improved useful agricultural implements, from Europe and America, into India, has been largely due to two causes, namely—

- (i) That the requirements of the country were not known;
- (ii) That the art of working the implement introduced was not understood by the party to whom it was sent to instruct the cultivator in its use.

Often has it been the case that the instructor has been unable to use the new implement, as well as the cultivator used his crude home-made implement, the art of which crude implement the instructor himself was equally ignorant of. Often have I seen in official reports from the district officials, that the cultivators said this or that about the new implement, giving some imaginary defect that the district official could not explain away; or it might be, that the implement was not being properly worked; or, yet again, the implement might have been tried for some work for which it was never intended and entirely unsuited, all of which the instructor was ignorant of. This cannot be complained of. The district official had never before had occasion to learn the use of any agricultural implement, and yet he was the best available instructor to whom Government could entrust it for practical trial. With these facts before you, are you surprised that so many useless implements have been tried, and also so little favour has been shown by cultivators for really useful implements? The wish that others may benefit by my experience, which I have learned from hard, practical tests, has induced me to state the following facts, that they may be of service to those who take an interest in the cultivation of the soil.

America appears to me to be the country to which we here in the East must look for improvements in agriculture and agricultural implements, owing to its geographical situation, to

the interest taken in agriculture, and to the tendency of its people to cultivate the soil as cheaply as possible by the use of the best machinery and implements. For both America and India the best implement that I have seen, to commence cultivation with, is the *turn-plough*. The turn-plough is a plough that turns the soil to one side, and either inverts, or partially inverts, the soil. The top and the bottom of the furrow is about the same width. If the soil is entirely inverted, hard rain will cause it to run together and become hard again earlier than if it was partially turned. If there is grass on the surface, and seed will be sown in a short time, it is best to turn the soil over completely and thus destroy the grass. For improving the soil cheaply, a crop sown on it and then turned under the soil, while green, is ordinarily the best mode. This the turn-plough will do with any kind of plants that will bend easily, such as rice, jute, indigo, &c., without the plants being cut, even if they are four or five feet high. To do this, attach a heavy chain from the beam of the plough to the handle so as to bend the crop in the direction in which the plough is going. Land ploughed with a turn-plough, and left so, will be dried by the sun's rays much more quickly than if ploughed with a plough that does not invert the soil. The *Watt* turn-plough is the best plough that I have yet seen for general ploughing. The *Shovel* plough is shaped like a pointed shovel and throws the earth both sides. Its furrow is much broader at the top than at the bottom. It is used to re-plough land, and also to cultivate between the rows of a crop that is planted in lines. Its draught is very heavy, considering the amount of earth cut. It is therefore unsuited to commence preparation of the soil with. The *Trowel hoe*, or sub-soil plough, does not turn or throw the earth. It is trowel-shaped, with a stanchion handle placed at right angles to the share, or trowel, and is used for aerating the roots of plants and stirring the soil when there is no grass. It is scarcely used at all now. The *Drag*, or *Harrow*, is a frame containing a number of teeth, and is used for pulverizing the soil after it has been ploughed with the turn-plough, and also for cultivating a growing crop. It may contain any number of teeth in proportion to the size of the frame.

The cheapest preparation of the soil that I can recommend is, if the land is in ploughing condition, and not foul, plough once with a turn-plough, harrow once with a harrow, and then pass a trough-shaped beam (trough side down) over the surface of the field. The soil then will be in a condition to be seeded with almost any kind of seed. It will always be well to remember—

- (i) That land ploughed with a turn-plough has a tendency to dry rapidly ;
- (ii) that land entirely turned with a turn-plough will become hard again much more quickly, if entirely inverted, than if partially inverted ;
- (iii) that land ploughed with a shovel-shaped plough, if it is a rolling (hilly) surface, has a tendency to cause the soil to wash away ;
- (iv) that ploughing with a shovel-hoe plough tends to prevent the soil from washing, and it will also retain moisture longer than if cultivated with any other implement.

For rice-cultivation in Burmah.—At present I would recommend that the land be ploughed once at the beginning of the rains with the turn-plough, entirely inverting the soil, and that afterwards it be ploughed, when necessary, with the usual Burmese implement ; and just before planting or sowing, a log of the afore-mentioned trough-shaped implement be passed over the field.

For kaing-cultivation.—Plough once with the turn-plough just before the end of the rains, entirely inverting the soil, and afterwards cultivate with the usual Burmese implement when the land is dry enough to be prepared. Pass the log or trough (hinger*) shaped implement over the field, and it is ready to be sown or planted with any kind of seed or plants grown in kaing-cultivation in Burma.

In connection with ploughing, it may not be out of place for me to mention here that *hot sunshine* is injurious to the soil. Land therefore that has any protection, or anything

on it to shade it, should not be ploughed until the last moment. For instance, rice-fields in Burmah should not have the stubble burnt on them until just before the rains. After the rains commence, the sun's rays are obscured by the clouds and they have little effect on the soil. If the stubble is not burnt at all, but left on the land and ploughed into the soil, the field will improve, but the crop that season will not be as good as if it had been burnt, because the stubble will not have decayed in time to be used as plant food that season, whereas the ashes would be taken up at once by the young plants.

In America, during the winter season, like the rains in Burmah, the sun's rays are very weak, so ploughing is done during the winter for spring sowings, but never during the summer until the last moment for autumn sowings. To illustrate this, wheat is sown often on fallow land about the 1st October. Vegetation in America is at its best growth during June and July, and in making a fallow your idea is to put as much vegetation into the soil as possible, and you also wish to have this vegetation sufficiently decayed at the time of sowing to be available as plant food. With these two objects in view, you would be inclined to plough in June or July, and take vegetation at its highest, and also have more time for it to decay. Experiments have, however, proven that these two advantages are more than counterbalanced by the damaging effect of the sun during June and July, and the best time to fallow is during the month of August. In the North-Western Provinces of India I recommended that land be ploughed before the dry season, and remain so during the hot season, because during the dry season there is no protection of any kind on the surface of the fields ; the stubble being carried away for fuel, and the ground being left dry for grass to germinate at that season of the year. My reason for recommending this was that the sun has more effect on a hard, compact soil, than on a light, porous one.

RE-SETTLEMENT OF THE CENTRAL PROVINCES.

WE understand that Mr. CROSTHWAITE goes up to Simla next month, to discuss with the Government of India the arrangements to be made for the re-settlement of the Central Provinces, which are now within measurable distance of us. Under ordinary circumstances, we should not hesitate to recommend that the rates should be revised simply upon the *putwaris'* records, but the settlement of these Provinces is a solecism in the history of our administration of the land revenue. The settlement was made during one of those periods of reaction which have been so frequent in India, and in which all considerations of prudence and of the State necessities, have been over-borne by wild proposals to recast the fiscal system of the country upon such notions as those propagated by Sir RICHARD TEMPLE, that we had only to abandon the land revenue of the country, to find the Treasury overflowing with the yield of the custom house and the excise office. It was under this preposterous notion that the settlement of the Central Provinces was made, and the State share in the produce of the soil fixed for thirty years at an average of 8 or 9 annas per acre. The effect has been to hang these provinces like a mill-stone round the neck of all the others for the last thirty years. By the time the present settlements expire, these Provinces will have been allowed practically to lay the rest of India under a tribute of nearly thirty millions sterling, to defray their proper share of the general burdens. We have no doubt that Mr. CROSTHWAITE is as well aware of this as ourselves, and as no re-settlement of the Provinces can be made that does not very materially enhance the weight of the assessments, he may possibly think it absolutely necessary to re-survey the land. Under ordinary circumstances, we should desire to see the new assessments fixed and the new leases issued, upon the strength of the *putwaris'* records, without a re-survey. This would be of course the cheapest plan, and the least troublesome to the people, but the fact must be recognised at the outset, that the assessments will have to be doubled. They were pitched at rates that were insane, and that moreover at the very time when the State was constructing two most costly lines of railway throughout them : the line to Nagpore and the line to Jabalpure to Allahabad. Were an interprovincial balance-sheet made out for the last thirty years,

* This instrument is called hinger in Bengal and the North-Western Provinces, sara-un in Oudh, and kyandon in Burmah.

as it ought to be, the Central Provinces would be seen to have an arrear debt standing against them of 20 to 30 millions sterling, and to permit this state of matters to be stereotyped is impossible. We recognize the invidiousness of speaking of "doubling the impost," but we are speaking of what is absolutely necessary. If the Chief Commissioner of the Provinces and his district executive think it possible to increase the rates to this extent *without* a re-survey, well and good; but what must be absolutely resisted is any attempt to maintain the existing rates of assessment, or rates at all resembling them. For such rates mean either State bankruptcy, or the continuance of such injustice as we are perpetrating towards Burma, Oudh, and other provinces. The Central Provinces have fallen short by nearly a million sterling a year of their proper contribution to the Imperial burdens, and the wrong has lasted far too long already, and must be brought to an end.

Whatever step is taken, we trust the mistake will not be made of again fixing the rates for so long a period as thirty years. If a new survey is to be made at all, it must be the final one, and the assessments should not be fixed for a longer period than ten years. With everything in a state of flux around us, and the value of money changing incessantly and always in one direction, the State must reserve power to itself to revise the rates every ten years. This does not mean that they must necessarily be raised every ten years, but that the survey work being once properly completed, the rates shall be liable to increase at intervals of ten years, upon a mere Notification in the *Gazette of India*. We are approaching a crisis on this question of the land revenue, and it will not do to meet it with our eyes closed. The enormous expenditure already made, and yet contemplated upon railway extension; the fall in the value of money; and the monstrous inequalities which mark the present assessments, must be borne fully in mind. We have no desire whatever to see the Central Provinces re-surveyed, if the work is needless and the village records of the *putwari* can safely be made the basis of a new settlement of the assessments; but the Government must start with the full understanding that the present rates have been a gigantic injustice and folly, to be repeated no more in the country anywhere.

OUR CINCHONA PLANTATIONS.

The resolution of the Local Government on the Annual Report of the Government Cinchona plantations in Bengal, for 1884-85, brings to light some interesting facts. The total number of trees of all kinds on the plantations, at the close of the year, was no less than 4,912,111, divided as follows:—

Red (<i>Succubra</i>)	...	3,232,000
Yellow (<i>Calisaya Ledgeriana</i>)	...	1,086,118
Yellow (<i>Verde and Morada</i>)	...	183,300
Hybrid	...	385,100
Other kinds	...	25,593

The yield of dry bark during the year amounted to 330,201 lbs, of which 325,125 lbs. were red, and 14,076 lbs. yellow; the whole of this bark, with the exception of a small quantity, was made over as usual to the Febrifuge Factory for disposal. The quinine yielding varieties are those known as *Calisaya*, *Verde*, and *Morada*, of which 174,800 trees were added to the plantation during the year. These trees were raised from seed supplied in 1882-83 by the Secretary of State. These varieties are known in Bolivia to produce some of the finest yellow bark of commerce. But whether they are likely to be as successful in India is yet to be seen. It may, however, be hoped that they will, as their present appearance is reported to be healthy. The rich yellow variety, known as *Ledgeriana*, has also been extensively cultivated, no less than 231,900 trees having been planted out; while the hybrid varieties were increased by 84,600 plants. It is therefore evident that a considerable advance has been made in substituting quinine-producing sorts for those yielding the less valuable alkaloids. Dr. King, under whose able supervision the plantations are placed, again notices the continued failure of the Carthagena bark, and is of opinion that it will never be successfully grown in Sikhim. A quantity of *Bomija* seed, which produces a quinine-yielding bark, known as *Owron*, was obtained from South America, from which some 40 seedlings were raised; but the young plants are said not to look altogether healthy, and it is feared that the climate of Sikhim will not suit their growth.

The expenditure of the plantation amounted to Rs. 81,727, against the budget allotment of Rs. 97,803, thus showing a saving of Rs. 16,078. Rs. 12,480 represented the capital expenditure on the new plantation at Rungjung, and Rs. 69,247 the working expenses of the old plantations. The total amount sunk by the Bengal Government on Cinchona plantations and factory, since 1862, aggregates Rs. 10,84,202, which has already been recouped more than twice over by the saving effected in substituting the febrifuge for quinine in Government medical institutions. The cost of manufacture during the year was Rs. 12-5-11 per pound of ordinary febrifuge, and Rs. 18-8-11 per pound of crystalline febrifuge; the rates are higher than those of previous years, which is attributed to the large expenditure incurred in new fittings for the factory, and partly to the inferior quality of the bark used, as well as to the smaller quantity worked up during the year. The issues also show a considerable falling off, as compared with the previous year. Those for 1883-84 realized Rs. 9,144, while during 1884-85 the amount had fallen to Rs. 7,152-4. This decline is said to be owing chiefly to the medical depôts taking 1,658 lbs. less than in previous years; while the decrease in sales to the public is attributed to the great cheapness of quinine, the price of which during the year ruled lower than it has for many years. The revenue from all sources amounted to Rs. 1,24,225, and the operations of the year are said to have resulted in a profit of Rs. 37,582, giving a dividend equal to about 3½ per cent on the capital of Rs. 10,84,202. But we are reminded that these profits do not represent the whole of the gain of the year, as the saving effected by the substitution of the febrifuge in Government medical institutions for an equal quantity of quinine, which would otherwise have been used, amounted to Rs. 20,000. These results are satisfactory, especially when it is considered that cinchona seeds were distributed gratuitously to applicants during the year. Dr. King is therefore to be congratulated upon his efficient management of these plantations.

RAMIE, OR RHEA.

Continued from last week.

RAMIE is a perennial plant, and has to be planted but once for every thirty years. The planting is to be done exactly the same as with Irish potatoes. Work the soil well by ploughing. Trace rows three feet apart and plant the ramie roots in the rows at one foot distance; then cover with two or three inches of well pulverized earth. At a distance of three feet each, we will have seventy rows to the acre, and planting the roots one foot apart will give us 210 roots per row, or 14,000 roots per acre. In order to obtain a plantation of straight and well-formed stalks, the plantation must be made close and uniform. The present high price and scarcity of ramie roots would scarcely admit of the average planter investing at once in 14,000 roots per acre; but in order to push forward the propagation of ramie, I would suggest to planters the following scheme:

Leave a distance in planting of three feet between the roots, which, instead of 14,000 will make 5,000 roots, to the acre. In three months, when the roots will be about two or three feet high, spread them down in the rows without breaking. This will furnish for the autumn new stock which will complete the plantation up to 14,000 roots. Besides this, the planter can take from each mother-root two or three cuttings to plant another acre, and so on. As I have told you at the beginning, ramie is the most prolific of all plants, and Mr. E. Darby, of New Iberia, La., was right when he said to his son a few years ago: "I have planted a good acre of ramie in our garden. When I will be no more do not disturb it; take good care of it. If its utility is not appreciated to-day, the time will surely come when the true value of this plant will be universally recognized and you have in these roots the beginning of a fortune." Various Louisiana planters have in their fields some thousands of ramie plants which they could afford to divide. For my part, I have a large stock of the species *Tenacisima*, the best of all, which I hold at the disposal of any planter wishing to plant an acre or more of 5,000 roots, payable half cash, half in crude bark from the crops of 1887.

Planting being over, if the summer season is accompanied by a prolonged drought, it will be necessary, during the hot weather, if the soil where the ramie is planted is not naturally moist, to facilitate growth and vegetation by irrigation, which should be more or less frequent according to the permeability of the soil. Irrigation, however, must be stopped fifteen days before gathering.

to permit the stalks to fortify and lose their excess of moisture. The land should be disposed so as to permit easy watering. The best disposition consists in placing the plants on small ridges, separated by furrows which serve at the same time the purposes of irrigation and drainage. Like all plants whose leafage is strongly developed, ramie absorbs from the atmosphere a large portion of the elements necessary to its nutrition, consequently it does not exhaust the soil, and will prosper in ordinary ground, whilst hemp and flax need a very rich soil, which they speedily exhaust. It is good at each crop to abandon on the ground the leaves of the ramie plant, which thus return to the soil a part of the elements taken from it. It should not be inferred that ramie is indifferent to the action of fertilizers. Its vegetation is always proportionate to the elements furnished for its sustenance, provided always that they possess an assimilating nature. Therefore, as in the case with plants of rapid development, liquid fertilizers are the best. These should be used, mixed with water, in the spring and at every cutting. Farm manures should be employed only as a covering before winter, so as to permit the snow and rain to saturate the soil with its elements. During the first year the culture of ramie requires weeding round the young plants so as to rid them of noxious grasses. When, however, the plant has taken possession of all its allotted space, weeding becomes unnecessary, and the labor is reduced to giving in the spring one stroke of the plough to clean the draining ditches, and another one in autumn to cover the feet of the plant for the winter.

According to the Imperial Treatise on Chinese Agriculture the ramie stalks should be cut before the budding season, when their lower portion begins to assume a brown tint. The harvesting of stalks should be made with a very sharp scythe to avoid tearing, which would interfere with cicatrization. If the stalks are to be used in the green state, they should be made up in bundles of about 200 and carried to the machine. If they are to be used dry, they must be left to dry in the sun as rapidly as possible. This process offers some difficulties, as the stalks contain a great deal of water and are hydrometric by themselves. It will be necessary to use manual labor to turn over the stalks on the ground until they are dry. It is important not to gather them in until perfectly desiccated, for they would then rapidly become mildewed, which would also be the case if they were kept in a moist place. When it is wanted to utilize the ramie leaves for the feed of animals or paper-making, they should be stripped from the stalks at the time of harvesting.

It is important to bear in mind that ramie, like cotton, hemp and flax, presents varying qualities, according to soil, mode of culture and harvesting. In China, for weaving the finer tissues, a difference is made even between the fibrous strata on the same stalk. The exterior fibre is coarser and stronger than the interior fibre nearest the wood, which is employed in weaving silk goods. The first crop is shorter, branches off more than the second and third, and produces inferior fibre. Treatment in the green state not requiring that the plant should be fully matured produces a finer quality of fibre and allows cutting when the stalks are about five feet high. This gives also an advance of fifteen days on the crop, which in Louisiana would be making three crops. Practice will teach with more accuracy what will be best to do, for though the present information is derived from positive experience made in countries different from your own. The average value of the crude ramie bark has been estimated at five cents per pound. At that price there is a great European demand. In addition to this, let me tell you that it is by 100,000 roots that the villages in the south of France are now planting ramie, and since two months the prices of roots have risen 30 per cent. American consumption will, I think, enhance the price of five cents per pound of crude bark, for manufacturers here are at this very moment waiting for a regular and sure production to rear up their fabrics. However this may be, we are ready now to pay five cents each per pound for the crude bark of ramie, dried and baled, landed in New Orleans, where we establish a branch office. One acre planted now with 5,000 roots will have 14,000 plants at the fall and will produce in 1887 at least fifteen stalks per plant, and a total in round numbers of 200,000 stalks, giving one-eighth of an ounce of bark, or a pound by 125 or 130 stalks, or 1,600 pounds an acre per crop, or for two crops 3,200 pounds per acre, at five cents a pound, \$160. Putting down at \$30 the annual expenses, harvesting, and pro rata of first cost of the roots, we arrive at the splendid result of \$100 net profit per acre for two crops, and in Louisiana, with its lengthy fall, joined to the treatment in the green state, which requires less maturity in the plant and therefore less time, three crops are almost a certainty.

A certain proportion of the ramie crop will be applied to the fabrication of finer tissues. These will, of course, be a choice of qualities, but the true commerce of ramie will extend upon condition that the average quality of ramie will be produced at a price which will permit its advantageous use in the manufacture of tissues of general consumption. The price of five cents a pound for the crude bark corresponds with the good tissues which are now being manufactured from first quality of flax or wool. Under these conditions I would say to every intelligent American farmer: "Hasten to plant one, two, or three acres of ramie, enlarge your production each succeeding year, and, however large it might grow, there is no possible danger of too much ramie in the United States before twenty years to come. When that moment arrives, American genius will meet the emergency."

The great difficulty to overcome in making vegetable fibres useful as textiles, comes from the cement that attaches the fibres together and the colored pellicle which covers them. The substances to be eliminated for the utilization of these fibres are called, "vasculose, cutose and pectose," and our chemical process produces the effect of dissolving these substances, not only without weakening the fibre but making it stronger and more sky. Other processes have obtained a certain result by the use of caustic alkali with pressure, or such oxidizers as permanganate of potassium, hyperchlorate, chlorine and bromide, but these come high and consume more time than ours. We begin first by applying our dissolving agent to ramie with modifications according to the quality of the plants treated. For example, American ramie required 3° Beaume of our dissolvent, while the China grass, already somewhat cleansed, required only a bath of 2° with the same time in boiling, three hours. It is particularly the washing and depurating with plenty of water our chemical bath which should be done with great care. By this means a perfectly distinct fibre is obtained which we bleach and brighten up with our two other products—azotozone and chlorozone. The results obtained have won for us two first premiums at your Exposition.

It is in studying how to dissolve the gummy and resinous matters of the ramie that we have been led to treat almost in the same manner all the textile plants which grow, so to speak, at the very gates of New Orleans; the bananas and silk grass of Honduras, the pita and maguey of Mexico, Guatemala, Cuba, Jamaica, the lily of Florida, and the yucca of the Gulf Coast. I will not insist upon what I have previously said of the certain future of New Orleans as the first market in the world for all textiles. All I ask from this assembly is that a committee be appointed this very evening from among you to study the question specifically and technically with me, and to make a public report of all that can be imported in the way of fibrous product, free of duty, from Mexico, Cuba, Jamaica, Central America, Venezuela, Brazil, etc., and made into commercial textile fibre in New Orleans. Every innovation, as also every new culture, however useful it may be and bounteous its promises, must wrestle against routine and old established precedents, and must have the help of a high patronage. The Irish potato, without which people could scarcely exist at present, had a hard fight against routine and ancient customs, and the help of the Court of Louis XVI became necessary for the assertion of the claims of that useful plant to the patronage of Europe. The noblest ladies of that age wore the pretty little violet flower of the potato as an ornament, and in that way gave to flower and fruit the desired popularity.

Miscellaneous Items.

There is a report that an International Asiatic Exhibition will be opened in Tokyo in 1890.

The Ceylon Government has announced its intention of spending Rs. 50,000 to ensure an adequate representation of the island at the Indian and Colonial Exhibition.

A Tokyo journal states that a battle between immense numbers of frogs took place in the fields in Imada, Tokyo, a few days ago, and that 200 frogs were left dead upon the ground.

The want of rain is very much felt in Berar. A correspondent writes that, should the present dry weather continue, much injury will be done to the crops. The heat, he adds, is unbearable.

The Cawnpore market report, for the fortnight ending 29th June, contains nothing of importance. Business in almost all staples continues slack, without any immediate prospect of improved trade.

A DEPUTATION from the Bombay liquor-sellers, who have petitioned the Government of Bombay against a number of the Alkali regulations in force in that city, had an interview with Lord Reay, at Poona, recently.

A CORRESPONDENT telegraphs on the 1st instant:—His Excellency Lord Reay visited Lanowle yesterday in order to personally inquire into certain grievances brought to his notice in a memorial from the landholders. His lordship returned last evening in time for Lady Reay's first "At Home," which was one of the most largely attended receptions ever known here, there having been above 800 persons present.

NOTWITHSTANDING the present financial pressure, the Government of India have decided to make no reductions in the Bengal Exchequer estimates for the current year. It was feared that in consequence of anticipated retrenchments, there would have been some interruption in carrying out the recommendations of the Exchequer Commission, but under present circumstances, the Bengal Government will be able to push on the proposed reforms.

THE Chief Commissioner left Rangoon for Bassein for the purpose of being present at the opening of the Inajoi fishery in the Nathangyoung sub-division. We believe the sight is a very interesting one. The river, we are told, is bounded in certain parts, and at the opening season the bund is broken down, and all the fish rush into a vast reservoir or expanse of water, and the leasee and his people then commence their operations. Large crowds go to witness this opening event.

News from Cuttack, dated the 27th ultimo, says that the river has fallen two feet, and all danger to the town is now considered over. The sepoya patrolled the revetments during the two previous nights, and the water was then in some parts within two feet of the top of the earthworks. Heavy breaks are reported in the Pooree division, but no further accidents to life or property are yet announced. Passengers have succeeded in crossing the river at Cuttack. The Kendrapara lock entrance had silted up, but was being rapidly cleared.

WE learn from Bangalore that the locally manufactured spirits are to be sold in bottles in future to those of the public who may desire to go in for the liquor. Considering the number of liquor shops in which Europe-bottled poisons are vended, it seems very desirable that some more wholesome beverage should be sold to those who cannot afford to drink the finer kinds of spirits, but who will drink poison rather than nothing at all. We wonder what teetotal advocates, like Sir Wilfrid Lawson and his following, will have to say to the Mysore Government.

THE total number of deaths registered in Calcutta, during the week, was 150, against 144 and 184 in the two preceding weeks, and 52 less than the corresponding week last year. The mortality from cholera continues to be low, 14 deaths from this cause being registered, against 10 and 18 in the two preceding weeks, the quinquennial mean being 15. There were 4 deaths from small-pox, against 3 in each of the two preceding weeks. The fever mortality was also low, the deaths being 38 against 44 the average of the quinquennial. The general mortality was at the rate of 1 per 1,000 per annum.

THE total number of deaths registered in the suburbs of Calcutta, during the week ending 13th June, was 144, against 164 and 151 in the two preceding weeks. Under the head of cholera there were 17 deaths, against 26 and 30 in the two preceding weeks. During the week under notice there were 2 deaths from small-pox, 61 from fever, 19 from bowel complaints, 1 from injury, and 44 from other causes. The general mortality was at the rate of 29.8 per 1,000 per annum, against 33.9 and 31.8 in the two preceding weeks; while it was 22.1 in Calcutta during the same period.

THE total number of deaths registered in Howrah during the week ending 13th June was 37, against 40 and 60 in the two preceding weeks. Under the head of cholera there were 3 deaths, against 3 and 15 in the two preceding weeks. There were 11 deaths from fever, 9 from bowel complaints, 3 from injuries, and 11 from other causes. There were no deaths from small-pox. The general mortality during the week under notice was at the rate of 18.2 per 1,000 per annum, against 19.7 and 29.5 in the two preceding weeks; while it was 29.8 in the suburbs, and 22.1 in Calcutta, during the same period. Howrah would therefore seem to have been healthier than Calcutta, not to say the suburbs, during the week under notice.

A CORRESPONDENT writes:—Surgeon-Major Little, the Sanitary Commissioner, Berar, is doing his utmost to introduce indigenous plants for medicinal purposes in the province, and so far his efforts have been very successful. There are many medicinal plants in the districts which are considered almost as good as "European medicine." For instance, the "red pills" are said to be an infallible specific for the "Berar fever." The *tail gollies*, as they are called, I hear, have been largely distributed in the Booldana District by the Civil Surgeon, and the result is most satisfactory. It was time something were done to allay the fever.

THE latest official telegraphic report from Sreenugger, dated the 26th June, states that after three days' cessation, several smart shocks of earthquake were felt there, on the 24th and 25th ultimo. People who were returning to their houses have through fear gone back into tents.

THE Forest Ranger of the Musnagudi division has, we hear, been suspended for certain high-handed proceedings of his. It would appear that he compelled all cart-men passing Teppanadoo, from and to Mysore, to pay a fee of three annas per cart, on the pretext that they must, whether they required it or not, purchase a "brake." For this purpose a toll bar was erected at which a press of belted knights were placed, and who were empowered by the Forest ranger to arrest and charge any refractory cart drivers who refused to pay this illegal exaction. We believe there is no provision in the Forest Act compelling cart drivers to purchase a "brake," nor is there any penal provision which entails arrest and trial for refusing to accept and pay for a "brake." This unauthorized proceeding has, we are told, been in existence for more than a month, and we would enquire—where were the police? We trust that the district magistrate will cause a searching enquiry into this scandal.

THE last number of the *Gazette of India* contains the returns of accidents on Indian Railways, for the fourth quarter of 1884. As compared with the corresponding period of the preceding quarter, the number of accidents to trains, rolling-stock, permanent ways, &c., show a decrease of 47, or 13 per cent, against an increase of 1,104 miles, or 10.63 per cent, in the main mileage open, out of 481,162 miles, or 5.02 per cent, in the train mileage. During the quarter under review there were 612 accidents, in which 11 passengers were killed and 33 injured, while of railway servants four were killed and seven injured. The Government of India draws the attention of the officers concerned to the increase in the number of accidents on the Eastern Bengal, Northern Bengal, and Cawnpore-Achneyia State Railways, especially to the large number of cattle accidents on the Eastern Bengal State Railway.

ALL the records of the Inam Department, Hyderabad, were sealed up, and placed under a guard of the Regular troops. These records are now being removed from the Inam office to Ikram-Alla Khan's house in Sifeabad, and this removal has given rise to the wildest rumours in the city, implicating the highest officials in the Inam Department; but there is absolutely no foundation for them. The sole reason for the removal is the insecurity of the building hitherto used as the Inam office. The military authorities who are now responsible for the safeguarding of the building reported that it was impossible with any guard of ordinary strength to protect it thoroughly, and the Inspect-General of the Revenue Branch, fearing that interested parties might set fire to the building, obtained sanction for the removal of the records to a place of greater security. Information is pouring into the Inspect-General's office of cases in which the *sumuds* are suspected to be forged. All of these are to be carefully inquired into, but as the Inam records consist of some 30,000 cases, it will be some time before the actual extent of the frauds is known.

AN interminable correspondence in the papers, about insects as food, has at last reached its limit. A letter in the *Standard* assures us that black beetles—the ordinary domestic beetles—when properly dressed, form "a most delicious condiment." Here is the recipe for beetle paste:—

Catch your beetles in a soup plate filled with vinegar, and keep them soaking for six hours. Then turn the beetles out, and dry them in the sun for at least two hours, when the outer shell can be easily removed, the flesh then resembling that of a shrimp, to be put into a gallipot and mixed up with flour, butter, pepper, and salt, to a thick paste. Bake in the oven for two hours, and, when cold, serve with bread and butter. This is the *no plus ultra* of insectivorous discovery, and will be an inexhaustible food supply for the people it opens up! It only remains for some one to try it. Who will be the bold man? Mr. Labouchere, who so much envied the Kassala garrison their donkey, will, we are something authoritative about potted beetle. Meanwhile, we await with interest the countermove on the part of Keating's "Insect Powder" and Mr. Rowland Ward's "Insect death."

THE *Pioneer* says:—An example of the wisdom with which cities are governed—when the Government happens to be that of an Indian municipal committee—has just been afforded at the expense of the residents of Allahabad. People there who, during the rains, in the general scarcity of vegetables, relish a well-dressed dish of Indian corn, are in future to be deprived of that luxury. The city fathers, in their wisdom, having ruled that "no high crop of any description shall be allowed to be grown in compounds and sites situated within the Civil Station," the municipal inspector has during the last week been reporting as an infraction of this bye-law every patch of half-a-dozen maize stalks he could find growing in any one's garden, and now warning notices are being issued calling attention to the penalties provided for the daring individual who has the boldness to disregard such an absurd regulation as that quoted above. The absurdity of it is evident when one considers that if the bye-law forbids the growth of *blattas* in the hot weather, it must also prevent the growth of any but dwarf varieties of peas in the cold; that French beans will become an impossibility, and that balsams, hollyhocks, and other high growing annuals in the flower-garden are probably doomed. It is doubtful also whether the regulation, as it stands, will not prevent the growth of fruit of almost every kind. A "crop" of mangoes, plantains, or guavas, is in every sense a *higher* crop than one of maize.

The Khasi Hills are well known for their extraordinary rainfall—Cherra Punji, on their extreme south, is noted as the rainiest place in the world—but the official returns of rain-gauge readings for the three stations in those hills, for the week ending June the 18th, are truly astonishing. Shillong lies in the centre of the hills, Cherra Punji 32 miles due south, and Yowai 33 miles due east of that place; and the readings were:—Shillong 9.80 inches, Cherra Punji 36.43 inches, and Yowai 64.79 inches. In Yowai 51.5 inches fell in 48 hours, and although 40 inches have been measured in 24 hours at Cherra, a contemporary believes that 50 inches in two days is higher than any previous rainfall on record. The comparative paucity of rain at Shillong is due to the fact that it lies in a basin shut in on the east and on the south by hills rising 1,500 feet above it, which effectually take the edge off the rain-clouds. It is little to be wondered at that the Deputy Commissioner has started in hot haste for Yowai, overwhelmed with reports of the carrying away of bridges in high and hitherto dry ravines, and of the flooding of all the valleys that connect it with the plains.

It is pleasing to all interested in the study of Indian numismatics, the only remains of many dynasties of sovereigns, to know that the science of numismatics has found a munificent patron in the person of his Highness the Maharaja of Cashmere and Jummoo. His Highness has lately obtained possession of the largest collection of the coins of Cashmere yet made. This collection contains the coins of over thirty of the old Maharajas, who ceased to reign about the year 1300 A.D. It also contains 25 square silver coins of the old Sultans who were put an end to by Akbar; the copper coins of the same Sultans are numerous represented. Nearly all the Mogul Emperors struck rupees in Cashmere. These are fairly represented in the collection. Ranjit Deo, King of Jummoo, struck coins in his mountain home, the abode of safety, both in his own name and in the name of Shah Alam of Delhi. These are in the collection. After the Moguls, the Durran kings tyrannized over Cashmere, and struck beautiful coins there. Taimur Shah, Shah Zaman, Shuja-ul-Mulk, Mahmud Shah, Ayub Shah, Kalsar Shah, and Kutub-ud-Din are represented in the collection. But besides these, which are all coins of Cashmere and Jummoo, the collection contains many others representing kings who have at different times governed the Punjab, and whose names are well known to students of history. His Highness was pleased not only to confer a khilafat on the gentleman who made this collection (it took him fifteen years to complete it), but to appoint him Honorary Numismatist to his Highness. And permission has been granted to dedicate "the square silver coins of the old Sultans of Cashmere" to his Highness. It is thus, says the Lahore paper, the native princes of the Punjab encourage efforts to elucidate the history of the countries over which they rule.

Selections.

SWEET ENSILAGE.

[By PROFESSOR SHELDON.]

The subject of ensilage is receiving quite an extraordinary measure of attention at the present time. An Ensilage Commission is sitting in London, many experiments are being made by farmers and by scientific men, and quite a number of treatises have been published on the question, so that we may hope for a great deal of reliable guidance before long. The most important book yet published is written by Mr. George Fry, F.L.S., and issued by the Agricultural Press Co., of Clement's-Ion Passage, Strand, London, W.C. In this treatise, Mr. Fry divides the subject into the theoretical and the practical, and covers both branches in an able and authoritative manner. He fairly said that Mr. Fry has gone deeper into the question than probably any other practical man, and deeper than most scientific men, and it would appear that the system of producing 'sweet silage,' whose adoption, I believe, is due to him, will become the prevailing system of the future in this department of agricultural economy. The great objection hitherto entertained against the principle of preserving forage in a succulent condition has rested in the sourness of the silage, which was calculated to injure milk produced by its aid; and the principle has been more or less discounted by the unsustained nature of certain extravagant claims that were made for it, claims to the effect that it would supersede hay-making and root-growing, and would convert coarse herbage and even weeds into nutritious food that stock would relish.

This was the ordinary sour ensilage process that was introduced first of all to the notice of the British agricultural public, and which, very wisely, had cold water thrown upon it by such sound and eminent men of science as Sir J. B. Lawes and the late Dr. Voelcker. But the sweet process is, in its results, a very different thing, and Mr. Fry gives, in the book I have mentioned, a very lucid account of its scientific and practical aspects. In the first portion of the book, he points out that plants contain substances which belong to two distinct classes—those which are formed of carbonic acid and water, which are called carbohydrates, and those into the composition of which nitrogen enters—albumenoids, &c. The carbohydrates—cellulose, starch, and sugar—do not change into alcohol, acetic acid, lactic acid, or butyric acid, without the intervention or agency of living 'cells.' These 'cells' are the organized ferments, some of them belonging to the animal and others to the vegetable world, which are illustrated by such organisms as bacteria and the yeast plant. Milk and blood are well known to be among the most quickly perishable of fluids, but it has been repeatedly demonstrated that 'the gases of the atmosphere alone are unable to cause any material change in these

fluids, and that, consequently, if they are maintained absolutely free from ferments or their germs, milk can be preserved from sourness and blood from putrefaction for several months.

This germ theory lies at the foundation of Mr. Fry's system of sweet ensilage, and it is by controlling the process of fermentation which takes place in the silo that the result in his case is sweet instead of sour silage. The juices of plants are, like milk and blood, subject to fermentations, particularly when the plants in which they circulate are massed together as in a silo, when the circulation has ceased, and the whole mass is inert and in darkness. The fermentive organisms exist in myriads in the air, and many of them are carried into the silo with the forage; but their energy is not destroyed by excluding air from the silo by pressing the forage into a solid mass under heavy weights. The ferments exist on oxygen, it is true, but when they are thus denied the free oxygen of the air, they feed on the combined oxygen in the carbohydrates of the plants; and in respect to alcoholic ferments, the work they perform is in inverse ratio to the amount of free oxygen to which they have access—that is, they are driven by the necessities of existence to convert, during their search for food, a larger quantity of sugar into alcohol. Living forage is able to resist the attack of fungi and bacteria, because its cells are active and perform the digestive functions of the plant; but when the plant is severed from its connection with the earth, it slowly dies, and its cells die with it, and in this moribund condition the work of decomposition at once commences by means of ferments—as long, that is, as the plants contain oxygen and moisture in quantity sufficient for the sustenance of the ferments. Remove, however, the moisture, as in the case of hay-making, and there is no longer food enough in the forage for the ferments to subsist upon, and when the hay is in a solid rick free oxygen is almost wholly excluded. The interior of a rick of well made hay will keep good for years, but every one has noticed that the outside of it, which is still exposed to air and damp, commences to decay from the first.

The process of ensilage is wholly different from that of the hay-making, and requires much more care in order to secure a successful result. So long as the cells of plants are living, which continues to be the case for some little time after the separation of the plants with the earth is severed, the action of ferments is frustrated by the evolution of carbonic acid on the part of the plants; and this is the primary reason why ensilage may be preserved in a silo, for dead vegetable matter put into a silo, and still containing its normal moisture would not be preserved in a state fit for food for cattle. Mr. Fry quotes Messrs. Bollamy & Lechartier as follows:—

'At the moment when fruit, grain, and leaves are detached from the plant which bears them, life is not extinct in the cells of which they are composed. This life is carried on apart from air by consuming sugar and producing alcohol and carbonic acid. The instant that the production of carbonic acid ceases is also that when all vitality in the cells is extinguished. Fruit, grain, and leaves may then remain in an indefinitely inert state if an organized ferment is not developed in their interior.' Ferment lies the kernel, the secret of the process. During the short time they continue to live in the silo the vegetable cells convert starch into sugar, and in doing so heat is evolved; the thing to be attained is to arrest the process at the right moment, not by checking the evolution of heat, but rather by encouraging it up to a temperature of about 140 degs. F., which has the beneficent effect of destroying the ferments, which would otherwise begin to do their nefarious work so soon as the vitality of the forage in the silo was extinguished.

The heat in the silo is caused by the absorption of whatever free oxygen may be available, and by the evolution of carbonic acid—a chemical process in vegetation under these conditions which Mr. Fry terms, very happily indeed, 'intercellular oxidation.' The temperature attained in the interior of the silo depends mainly on two conditions—the quantity of oxygen introduced with the forage, and the quantity of water present in the forage. The normal moisture of the forage is all that should be present, and rain water additional is a deterrent to the desired temperature. If the vegetable cells are still living when all the free oxygen has been consumed by them, they will maintain the short remnant of their existence upon the combined oxygen of the sugar, during which alcohol will be produced and more carbonic acid evolved. This chemical process Mr. Fry terms, also happily, 'intercellular fermentation,' to distinguish it from ordinary alcoholic fermentation. In regard to this feature, Mr. Fry has come to the conclusion that 'alcoholic ensilage is produced by the action of the cells of the ensiled plants, and not by independent organisms.'

With the transformations last mentioned, the action of the cells comes to an end, and subsequent changes of a similar character, when such changes take place, are of a more serious and deleterious nature. 'No kind of acid fermentation is produced by the cells of the plants,' he says; 'therefore, in producing some ensilage there must be a loss caused by the transformation of nitrogenous substances as well as in that of carbohydrates.' The produce of aldehyds from alcohol is a process of oxidation, and acetic acid is produced by a further step in the same direction. The oxygen necessary to produce these changes must be obtained from some other organic substance in the silo, probably one containing nitrogen. The production of acetic acid is accompanied by a loss of feeding properties in the silage, and can only be avoided by the destruction of the germs, the *mycoderma aceti*, which produce it, which is done when the temperature of the silage rises 60 C., 122 F.)

Various other kinds of fermentation are produced in a silo, unless means are employed to prevent them, and of these lactic acid is one of the most important, and desirable to be avoided. The mode of producing lactic acid is not as present so clear as that of producing acetic acid; but if a silo be filled rapidly, and every layer pressed down well by treading, or by other means, if every precaution be taken to exclude the air, and the forage be covered up quickly

and weighted, then the silage will be sour, and by on account of lactic acid. Mould or mildew is produced by the presence of sufficient air to start the spores into life when the cells of the plants are moribund or dead. While the cells of the plants remain alive and vigorous, producing intercellular oxidation, they resist the attacks of organisms, such as fungi and microbes; and the heat evolved by them, if it reach 140 degs F., or so, is sufficient to destroy the fermentive organisms which may be present, and the result is sweet instead of sour silage.

The foregoing is the scientific aspect of the system of ensilage, and, taken by itself, appears a formidable thing. Similar explanations, however, might be given of various other matters with which the farmer is almost daily concerned, so that after all there is not much to be alarmed at in it. The ordinary practical farmer cannot be expected to work out for himself these transformations in matter, and the causes of them; but as he holds in his hands their practical application, it is just as well he should know that he is constantly in company with most interesting and intricate natural phenomena, all of which are more or less amenable to the treatment which is recommended by common sense and experience. In my next article I purpose dealing with the practical aspects of the ensilage question.—*North British Agriculturist.*

THE OPIUM TRAFFIC.

The *Standard* is in a position to state that, although the new arrangement relating to the opium traffic has not yet been signed, and may not be formally concluded for two or three weeks, it has been practically accepted by the Governments of China and England, and there is not the least doubt that its provisions will come into force almost immediately. "The arrangement takes the form of an additional article to the Chefoo convention, signed by Sir Thomas Wade in 1876, and one of the clauses or sections of this article requires its ratification, and with it that also of the Chefoo Convention, as it may be amended or altered by this additional article. The two principal stipulations contained in it are the abolition of the inland barriers for opium, and the adoption of a uniform rate for lekin. The uniform rate of lekin is to be 60 taels per chest while the existing customs duty of 30 taels per chest—established by the Treaty of Tientsin—remains unchanged. Hitherto lekin has varied with the port, ranging from as high as 85 taels in some parts, to as low as 21 taels in others. The adoption of a uniform rate will remove any existing cause of discontent; and the lekin will henceforth be collected by the maritime customs officials instead of by the lekin officers, there will be considerable saving to the Chinese Government, at the same time that all room for uncertainty will be removed, as to the whole importation of foreign opium paying its full amount of lekin into the Government coffers. There will also be an improvement in the mode of collecting the lekin, for opium will henceforth be deposited in special receiving-houses which will in the course of a little time be converted into bonded warehouses, and the lekin will be paid to the customs officers before the purchaser can remove the opium. The payment of 90 taels, or 30%, per chest, will frank the opium throughout the whole of China; and the principal barriers will cease to have any significance in the matter of opium although they will remain in force for other articles of commerce. The arrangement is considered to be most satisfactory by both Governments; and the extension of the same principle of levying both the customs and the lekin at the ports, to ordinary merchandise, seems likely to occur within a reasonable period of time, when articles of foreign production will be able to reach the interior of China on known conditions, and without being subject, as at present, to the virtually prohibitory tariffs of the inland barriers."

Commenting on the above statement, another contemporary says:—"The announcement that the opium trade with China is to be placed on a more satisfactory footing is matter for congratulation. Our business with the Celestial Empire is so considerable, and Indian finance is so closely concerned in it, that England must benefit by anything that gives greater solidity to our relations with the Government of Peking. Nothing is more fatal to the highest prosperity of commerce than vexatious and uncertain tariffs, and the Governments of London and Peking will have done excellent work if they have brought the markets of China, India, and England into closer working proximity. The inner wealth of China has yet to be tapped, and English manufacturers will not be the worse for any stimulus afforded to their productive energies. The East may yet make up for the injury inflicted on this country by the European and American protective systems. We may trust that the Governments of India and England will not forget that China has a western, no less than an eastern side. Yunnan, one of the wealthiest of its provinces, is approached most easily by the valley of the Irrawaddy. If it could once be joined efficiently with Rangoon and Moulmein there would be a splendid opening for our men of capital, enterprise, and industry. Unfortunately, the wretched King of Burma, Theebaw, blocks our road, to some extent, at Mandalay; but if we understand Mr. Colquhoun rightly, we need avoid that unpleasant monarch by running a railway through the independent Shan States. It is certain that the northern inland country of the Indo-Chinese peninsula, and the southern inland country of China, have potentialities of immense wealth. Horrible as the tyranny of the Burmese king is, and oppressive as his system, or want of system, in hardening his people with impure the exports and imports between independent and British Burma in 1880-81 reached a sum of over 3,000,000. These territories maintained in ancient times enormous populations and the ruins of vast cities go to bear out the discredited stories of the Portuguese traveller, Pinto. The trade with Yunnan and

with the Shan States only wants opening up, and then, if the irresponsible ruler at Mandalay is kept in order, a splendid future awaits the English provinces on the eastern shore of the Bay of Bengal. As trade follows the flag, the increase in riches of our possessions will be felt at home. The interior of China reached through Yunnan, and not harried to the trader by the fickle whims and whims of officials, will be a most sensible addition to the world's markets. Still, promptitude to seize opportunities and vigilance as against rivals are needed in our Ministers, as it is notorious that French intrigue has lately been very busy in Bangkok and Mandalay. Supine might lose England and India much that they can ill afford to lose. The magnificent lands on our North-eastern Indian frontier are the natural trade appanage of our Eastern dominion, and we cannot allow our influence to be ousted from them. We have been so busy rearing in various parts of the world, that it would be a change full of relief to the nation to know that in one region at least we had managed to maintain a firm footing, if we did not advance. There is another aspect of the new opium arrangement which is worth consideration. The opium trade with China has been a frequent subject for vituperation on the part of a certain class of philanthropists. These men have insisted that we were poisoning the Chinese with the deleterious drug in their own despite, and in order to put money in the pockets of that great power of opium, the Indian Government. The Chinese now see that prohibition is a failure, and as men will have what they have a craving for, they are trying their best to organise the trade on a sound footing. The outcry against the great source of traffic between India and China was wrong-headed and unreasoning. Like other good things the narcotic which so many Chinamen love to inhale in the form of smoke could be used to excess. Poor compatriots of Ah-Sia would spend a great deal more than they could afford on the very soothing pipe, and some of them, no doubt, were brought within a measurable distance of the Celestial equivalent of our work-house by undue indulgence. But a few cases of excess were no sufficient reason for depriving tolling millions of the human family of the main luxury of their lives, of a solace "full of sweet dreams, and rest, and quiet breathing." Even if that staff of contemplation, the opium pipe, were so mischievous an institution, as it has been said to be, the Chinaman, like the Englishman, was not likely to be compelled to virtue by severe measures of repression. Now, however, that the Peking authorities are to be thirty pounds in pocket for every chest of opium imported into their country, they are not likely to quarrel with what is so handsome a source of revenue, and our sterner moralists in England will have much of the ground knocked away from under one of their pet grievances. In any case the world must benefit by every fresh step made by China towards bringing itself into more complete harmony with the commercial conditions of the times in which we live.—*Overland Mail.*

COFFEE CULTURE IN AMERICA, ASIA, AND AFRICA.*

THE volume which invites the following remarks, though it cannot be called entertaining, will certainly prove interesting, not only to the "apostles of temperance," but to the thousands of people engaged in the production, sale, and consumption of the fragrant coffee berry. The Dutch Government have recently become alive to the fact that the Brazilians are running them out of the market, and their not unatural desire to ascertain the cause led to the sending a special mission to South America, and to the collection of the mass of statistics and evidence before us. Brazilian coffee is now consumed everywhere; in France, Germany, Sweden, Norway, Denmark, Italy, Portugal, Russia, and even Turkey, there is no Brazilian coffee consumed than any other sort. Now in Dutch India there are about 22,000,000 people directly interested in the coffee trade, in Brazil there are only about 4,000,000 affected by it. The other coffee-producing regions of the world are Venezuela, with 1,000,000, and the United States with about 9,000,000, interested in the trade. These figures, of course, give the populations affected by coffee culture, not the number of people actually engaged in the trade, which is necessarily smaller; but they serve also to point a moral, for when added together, they amount to 37,000,000 people; but in Ceylon, Malacca, and Borneo, there is an aggregate population of 70,000,000 interested in the coffee plant. Thus it will be seen that Great Britain has a stake in the affair twice as great as that of the rest of the world combined. The consciousness of the great importance of the subject to the British is the probable cause of the Dutch report appearing in the English language.

The author goes into the question with Teutonic minuteness, giving the physical and geological characteristics of Brazil, the history and politics of the young empire, its trade, banking transactions, railways, its finances, and domestic institutions—i.e., slavery. Brazil is much in want of slaves, but modern society has cried out upon the institution, and it has been condemned. The slaves now existing are sooner or later to be set free, and fresh importation is stopped; accordingly, the great problem is the provision of cheap labour. This circumstance has made the slave master of the situation. His life has to be cherished and his convenience studied, he is carefully clothed and even extravagantly fed, thoroughly trained physicians attend upon him in sickness, schools are provided for his family, and he is taught music, and encouraged in innocent dramatic and other pastimes to please his mind. Every reasonable effort is now made to prolong his useful life, although the corporal punishment is inflicted, it is done in deference

* Brazil and Java. Report on Coffee Culture in America, Asia, and Africa, to H.M. the Minister of the Colonies. By C. F. van Beldon. London: With Plates, Maps, and Diagrams. W. H. Allen and Co.

to the wishes of the slaves themselves, who prefer to be thus chastened for their offences rather than endure the *exilium* of a galley. Still, the day of free labour is approaching, and in a few years will have to be in full operation. No less than 148 colonies have been started, but they have all miserably failed, and are doomed to inevitable failure, because no free man can work in competition with a slave. Thus while slavery exists there can be no free labour; and yet free labour must be got into operation before the extinction of slavery. The number of slaves is, however, very small, there being only 284,000 of them altogether, and a bold effort might be made to buy up the lot; but, alas! the Brazilian expenditure already exceeds the revenue to such an extent that the accumulated deficits of the last ten years have amounted to 294,942,774 milreis, or about 30,000,000*l.* At the same time Radical reformers and abolitionists are disheartened in Brazil, as may be seen by the speech of Senator Martinho Campos in the Chambers on August 21, 1880. That outspoken representative did not hesitate to say that, "as for the abolitionists, I regard them as robbers, against whom I can use my revolver." Mr. Chamberlain's party would be met with something stronger than talk in Brazil.

The recent use of machinery has given to Brazilian coffee a great impetus, and the market has been extended by a judicious use of Exhibitions. Liberal quantities of carefully prepared coffee have been distributed gratis at close of these Exhibitions, with the natural result of creating a taste for the article. The Russian Government has also encouraged the introduction of coffee, with a view to the reduction of drunkenness. The labour question is the only real obstacle to the achievement of a great future by Brazil, for no country in the world offers greater advantages to the colonist. The Chambers, however, imitate the pattern institution in London, and waste year after year in talk, varied by mischievous interferences with trade, arising from the political manoeuvring of "those who govern" and "those who desire to govern." The extension of any branch of trade under such a government is a marvel, and it is still more marvellous to find such a country steadily displacing from the markets of the world one prime article of consumption.

The report before us deserves to be studied quite as much by the English as by the Dutch, and those engaged in the coffee trade ought to feel much indebted to the Dutch Government for procuring and publishing so much sound information on the subject. The maps of the various coffee-bearing districts are carefully drawn to a large scale, and tabular statistical matter appears to furnish all the details that the most inquisitive might desire to know.—*Overland Mail.*

A COLONIAL VICTORY OVER LOCUSTS.

[By Miss C. F. Gordon Cumming.]

WHILE war and rumours of war in each of the five great continents of the world form the all engrossing topic of thought and conversation, it is satisfactory to be able to note one hard-fought little war in which British perseverance has happily been crowned with eminent success. I allude to the Locust War in Cyprus, which has of late years filled so large a place in the history of that island. Though the ravages of these rapacious little foes have been an oft-recurring trial to the Cypriot husbandmen, frequently calling for Government intervention, the insect legions showed so alarming an increase about five years ago that it was evidently necessary to institute a war of extermination on a most systematic scale. This was accordingly undertaken by Sir Robert Biddulph, High Commissioner of Cyprus, from whose official reports we have from time to time been enabled to form some idea of the magnitude of the task. That such a hope as that of extermination was winged foe could reasonably be entertained is a fact that, unlike other migratory locusts which are the scourge of fertile lands in all parts of the world—notably, *Locusta*—the hungry hordes which devastate the fair fields of Cyprus are all born and bred on the island; no evil winged warriors from the mainland sweep them away, and they die in the land of their birth, and then each starts in its native soil the eggs which produce a hundred-fold increase in the ensuing year. According to Mahomed each mother locust lays ninety-nine eggs—Were the hundred complete," says the Koran, "they would consume the whole world and all that is in it!"

That this evil foe was in store for Cyprus appeared so evident, that, in 1880, it became positively necessary for the Colonial Government to take the matter seriously in hand and organize measures for the salvation of the island. It was therefore made compulsory on every male, between the ages of eighteen and sixty years, to collect a certain weight of locust eggs, to be paid as an annual tax to the Commissioners appointed to superintend this work of destruction in the three districts—namely, Famagusta, Larnaca, and Nicosia. It was stipulated that the egg-sacks must be delivered clean, without any admixture of earth; so we may form some estimate of how enormous was the diminution of the foe, when we learn that the weight of the tiny grain-like eggs destroyed in the autumn of 1880 was actually 236 tons. This, however, was far exceeded in the following year, for notwithstanding this wholesale destruction the remnant that escaped detection and survived to deposit their eggs was so great that no less than 1,330 tons weight of locust eggs were destroyed between July, 1881, and February, 1882. Nevertheless, so great was the multitude of cunningly buried egg-sacks which escaped detection that, when the hatching season arrived, there was apparently no diminution in the vast swarms of living locusts which presently appeared—hungry hordes, threatening

immediate famine, and suggesting ever-increasing legions for future years.

It was evident that measures for their wholesale destruction must be organized on a far more extensive scale. The preparations for war included such items as 5,800 canvas screens, each fifty yards in length; tools for digging great trenches, and payment of labourers, who were required to keep watch day and night wherever the presence of the foe was suspected. In the districts of Famagusta alone, 32,220 pits were dug, and all these were in due time filled with a densely packed mass of struggling locusts, the total weight of insects thus destroyed in this one district alone being above twelve thousand tons! It might well be supposed that such wholesale massacre would have effectually thinned the locust-legions. But again the survivors proved to have been numerous that the swarms of the following spring were actually as large as those of any previous year, and the official reports stated that they were still gaining ground. It was evident that yet more vigorous measures were requisite, so the infested area was sub-divided into smaller districts, each of which was placed under the closest supervision; 65,000 pits were dug, and 8,000 additional screens were prepared and kept in active movement, proceeding the march of the foe. While Government officers were thus energetic, they were sorely tried by the amazing inertia of the peasants, whose indolence even outweighed all ordinary prudence of self-interest. Thus the Government engineer, Mr. S. Brown, reports arriving at a village where he found "only a handful of old men and boys vainly working at the locust pits and screens, utterly unable to cope with the multitude of locusts which swarmed past them, actually crawling into the streets. To his disgust he found troops of able-bodied men (the owners of the lands and the crops which were in such imminent peril) idling at the cafes, and refusing to work, because, they said, "Government, having undertaken the business, would, of course, accomplish it, but that they did not choose to work for such a low rate of pay" (the rate offered being equal to that habitually given for hard work on the roads). Truly, in dealing with such people there was much to be said in favour of the Turkish system of compulsory labour which has only been abolished under British rule. In like manner when every nerve was being strained to discover and clear every locust breeding ground, news was received very late that a large quantity had hatched, and were already well grown, in an isolated district about thirty-five miles from any other locust bed. This must have been known to many peasants, and to the inhabitants of a neighboring monastery; but no one had the grace even to send information to the officials. Notwithstanding such drawbacks as these, which led to the escape of many insects as a reserve supply for future trouble, it is estimated that the locust slaughter of 1883 must have cost somewhere about two hundred thousand millions!

Although the locust crop of 1884 gave good proof of the benefits of this wholesale massacre, there was still good cause for vigilance and unremitting care. To the working material, also, there were added 3,800 zinc traps, made on a new and improved plan, and 2,860 canvas screens, making of these a total which, if judiciously employed, would have made about 315 miles of canvas wire placed in a line, divided into still smaller districts for official supervision, but the reduction in the number of the foe rendered a corresponding reduction possible in the force employed to cope with them. Only 2,000 persons were the force employed, of whom 1,400 were labourers working on contract. By judiciously marching these from one point to another they were able to do all that was requisite. At this point, however, a serious alarm arose for the locusts, having suddenly changed their line of march and outflanked their watchers, had actually reached the standing crops. In this emergency a working party of English soldiers was called out, and thirty-two men of the Queen's Own West Kent Regiment were marched out to do battle with this tiny but serious foe. It is superfluous to say they did their work right well.

To the joy of all concerned these long sustained efforts have at length been crowned with such success that last year literally no damage to crops was reported, and, though it is evident that there will always be a sufficient number of survivors to necessitate ceaseless vigilance, and the preservation of locust war material, as an annual item in the national expenses of the island, it may now be considered that the great plague has been successfully conquered. It is now proposed to render it compulsory on owners of the soil annually to plough all lands where deposits of eggs are known to have been made. Also that rewards shall be given (graduated according to the distance travelled) to all persons reporting hatches not previously known to Government, and that fines should be levied on persons who, knowing of such, have failed to report them. The total expenditure incurred in this warfare has been:—For the year ending June, 1882, about £32,000; for the year ending June, 1883, about £12,300; for the year ending June, 1884, about £9,000—a considerable item in the outlay of the island, but one which will very quickly be refunded by the rich harvests now happily safe from the all-devouring foe.—*Pall Mall Gazette.*

A SKILFUL SURGICAL OPERATION.

THE American Ambassador at Vienna, Mr. Kasson, has lately forwarded to his Government an interesting account of a remarkable surgical operation lately performed by Professor Billroth, of Vienna, which, wonderful to tell, consisted in the removal of a portion of the human stomach, involving nearly one-third of the organ—and, strange to say, the patient recovered—the only successful operation of the kind ever performed. The disease for which the operation was performed was cancer of the stomach, attended with the following symptoms:—The appetite is quite poor. There is a peculiar indigestible distension in the stomach, a feeling that has been described as a "lump" or "ball" sensation; a sticky slime collects about the teeth, especially in the morning

Miscellaneous Items

GOVERNMENT have sanctioned the sum of Rs. 1,54,000 for survey and settlement operations in Sind for the current official year.

THE Simla Naturalists Club was inaugurated the other day, Mr. Bert being elected President, and Colonel Crookshank Secretary. A goodly number of members was enrolled.

THE Katni-Umaria Railway is expected to be opened in November next, the line being one that will probably yield a revenue immediately it has escaped the financial pruning knife.

IT appears from the usual monthly return of shipments of tea from Calcutta that, from the 1st May to 30th June 1885, a total of 4,435,574 lbs. of tea have been exported to different parts of the globe, as against 2,295,870 lbs. in 1884, and 2,562,481 lbs. in 1883.

FRENCH brandy is sold in Pondicherry at the rate of ten bottles for Rs. 3-6-0, or equal to about Rs. 4-0-0 per dozen; and white rain Mauritius and Bourbon sugars are advertised at Rs. 50 per cwt. French sandy of 528 lbs. English—equivalent to one anna and six and a quarter pice per lb.

THE prospects of the rainfall in Bombay were certainly improved the other day. There were several heavy showers during the day, and although only one inch was registered on the Esplanade, where the fall seems to have been slightly above that in other portions of the city, there is every prospect of a continued downpour.

THE salt returns for April and May show a slight falling off, as compared with the same period of last year. The number of maunds sold during each of these months was 2,638,000 and 3,044,000 respectively, against 2,816,000 and 3,305,000 in 1884. There was, of course, a corresponding decrease in the revenue returns.

MR. M. FINEGANE, B.S., Director of Agriculture and Commerce, Bengal, visited the Board's Office on Monday afternoon, the 13th instant, to consider necessary measures, in consultation with the Honorable H. J. Reynolds, B.A., the Senior Member of the Board's Office, for the local Office of the Agricultural Office, Bengal, in the Board's office building.

THE total number of cobra snakes killed within the limits of the Civil and Military Station of Bangalore, during the past month, was 50. The destruction of these reptiles cost the local Municipality Rs. 16-2-0. The total number of dogs destroyed during the month of June last was 163, at a cost of Rs. 26-2-0, which was also defrayed by the Station Municipality.

THE *Indian Spectator* says: Mr. J. E. Mody, of 57, Hornby-road, has shown us some tea plants brought down by him from the Kangra Valley. He gives a very interesting explanation about the growing and preparing of the best varieties of tea. Mr. Mody seems to have brought with him over a hundred plants, at considerable expense, and he deserves encouragement.

INTIMATION has been received by the Government of India that a separate court will be set aside at the Colonial and Indian Exhibition, 1886, for private exhibitors, who wish to sell and deliver their goods during the Exhibition. Applications for admission to this court should be made to Messrs. King, Hamilton and Co., of this city, and Messrs. King and Co., Bombay.

A CORRESPONDENT writes to a Madras paper that a perfect cure can be obtained for cobra poison by taking pills made up of the following ingredients:—Ameium zedoria, Ophioxylon Serpentinum, Arsenicum Album, Arsenicum flavum, Arsenicum rubrum, Aristolochia Brachyloba, and Cardenia dumuto rum. An equal part of each of the above is to be mixed for three hours with betel juice, and made into small pills, three of which are sufficient to effect a cure.

MONSIEUR A. ROUSSEAU, Sub-Secretary for the French Colonies, has written to the Governor of the French Indian Colonies at Pondicherry, enquiring whether native gardeners can be engaged in the Franco-Indian settlements to proceed to Obok, to take service under Government for employment in the new public garden about to be established at that station. The primary object of the French Government is to obtain a supply of fresh Indian and other vegetables for the local market and the shipping; at present, green vegetables are quite unknown there.

THE Dewar of Mysore has ruled that a revenue sale should be stopped if payment of arrears of kandeiyam be made before sunset of the day previous to the date of sale. A payment or offer of payment after the sale is no ground upon which the Deputy Commissioner can cancel a sale. The Deputy Commissioner has the power (whether on his own motion or upon complaint of any party interested) to refuse to confirm a sale on the ground of some material irregularity, a mistake or fraud in publishing or conducting it, causing substantial injury to any person affected by the sale. If the Deputy Commissioner refuses on grounds above specified, he must cause a *re-sale* to take place. If he does not so refuse, he must confirm the sale within 30 days from date of sale. The Deputy Commissioner's attention is called to Sections 193 and 194 of Draft Revenue Code which contains the existing law on the subject.

SOME 40 inches of rain in five days at and below Kurseong, at the end of last week, and a steady downpour daily ever since, reaching 20 inches in 2 days, caused many slips which obstructed our little Railway; the obstructions are now reduced to one at the 12th mile, and this was expected to be cleared last evening, and then through communication would be restored. In spite of the obstructions, as most of our readers know, the Mail trains have been fairly well run to time, much to the credit of the staff.—We have just received information that through communication has been restored, and the working of goods traffic resumed.—*Darjeeling News*.

THERE is a composition known as "Mystery gold," which, in the hands of the nefarious, is an artful trap to catch unwary pawnbrokers. With a name which in these days of "strange titles" suggests a new sensational novel, "Mystery gold" is calculated to deceive even the expert "Uncle." Mr. Attenborough, an authority on the snares to which pawnbrokers are liable, explained in a recent case before a magistrate that a large number of sovereigns had been made of it, and circulated throughout the country. The composition, consisting of platinum, tin, and copper, stood the tests of the ordinary acids, and was of the weight of real gold.—*European Mail*.

A PECULIAR kind of fish was caught in the river off the East Gate the other day. Its skin is not covered with scales, but is smooth and velvety to the touch, if stroked from the head towards the tail, and rough if rubbed the other way. Between its eyes and extending forward is a horn about two inches long, while on each side of the tail-joint are two sharp spurs. The fins are large, the dorsal and belly fins extending the whole length of the body. A similar fish is said by the fish-sellers to have been caught over twenty years ago, though the specimen then obtained was much smaller. A gentleman who heard the fish was in the market purchased it, and has sent it to the Museum.

THE Chief Commissioner of the Central Provinces was to have left Pachmarhi on the 13th instant for Simla, on business connected with the new settlement of the Province, which is already under weigh in the eastern districts—Raipore and Sumbulpore. The last settlement was an easy one, as suited the circumstances of a young province; but roads and railways, then unknown, have now opened up the country and developed its fertile resources to such an extent, that an increase of revenue may be looked for without any fear of unduly burdening the agricultural classes. It is fortunate that the Province just at this time should have at its head a specialist, in Settlement work of such repute as Mr. Crosthwaite.

THE last number (7th July), and the first of the new volumes of the *Indian Planter's Gazette* received by us, shows that the proprietors are determined to make it a popular and attractive magazine—to wit, a new and ornamental cover. The reasons assigned for changing the old wrapper are, primarily, to make the journal "easily distinguished among other papers"—no doubt a very material point in these days. We are glad to learn that it has made such rapid progress during the short time it has been in existence; and it is satisfactory to note that it continues to be appreciated by those for whose benefit it was originally inaugurated. With a new era in its salmon covering, we wish the *Indian Planter's Gazette* the success which its enterprising proprietors deserve.

THE cyclone which broke over Rangoon last month blew down the new barn-like building in Pegu, which had been used as the Deputy Magistrate's Court House. Fortunately it occurred early in the day, when only a few attendants were in it, and except one person, no other casualties were experienced. The Court was moved into another thatched barn, formerly used by the Government Department, and where it will remain until next month, when the D. P. W. hope to have the new public buildings ready for their accommodation. These are pukka built, roofed with shingles, and promise to be an ornament to the town. As the place where the establishment was situated is not floored, it will certainly be to the advantage of the health of all concerned to get into a pukka building.

THE reductions which the Government of the N.W. Provinces propose to effect in the estimates of the current year, consequent on the financial pressure engendered by military necessities, amount to twenty and a-half lakhs. The main heads under which the retrenchment falls are as below:—

	Rs.
Land and Separate Revenue	1,00,000
Forests	50,000
Jails	2,50,000
Education	1,00,000
Minor Department (Under Director of Agriculture and Commerce)	50,000
Irrigation	1,50,000
Public Works—	
(a.) Railways	9,00,000
(b.) Ordinary	4,50,000
Total	20,50,000

Of these items of reduction, it will be seen, all are purely Provincial, except Forests—which under present arrangements are equally divided, both as regards revenue and expenditure, between the Imperial and Provincial Governments—and, secondly, two lakhs of the ordinary Public Works expenditure, which come under the head of Local.

MAIZE-MEAL RATIONS.

	Average Produce per Acre.	Assumed Price.	Estimated Money value per Acre.
Roots ...	18 tons 15 cwt.	10s. per ton.	£ 18 6
Barley ...	45-0 bushels.	4s. per bl.	8 8 7
Sheep-grazed seeds ...	8502½ lb. of live wgt.	7d. per lb.	10 7 11
Wheat ...	44-1 bushels.	4s. 6d. per bl.	9 18 6
Total value, eight years' average			£ 38 0 5

To account for this discrepancy between science and practical realization chemists have alleged that the comparative nullity of effect from nitrogenous matter in the cotton cake and in its equivalent artificial, is due to the large amount of unexhausted manure still remaining in the sand—which is a very light sand of about 9in. depth upon almost pure sand. It is for them to reconcile this theory with the fact that on the artificial manure plots in the self-same field the effect of nitrogenous manures has been found to be as marked as in ordinary experience upon stronger soils. A change in the experiments has been introduced, with a view of exhausting this supposed unexhausted store of manure in the land; this time, last year's wheat is being followed by man-golds unmanured and by Swedes grown with only 8cwt. per acre of superphosphate, and last year's barley is being succeeded by peas and tares grown without manure. Next year will, then, show if on the more exhausted ground-maize, meal dung will continue to give as high a result in crop as the dung from cotton-cake.

An experiment in feeding cattle on silage against others fed on roots and hay-chaff has been conducted since January 29th. In the first 60 days the animals increased 1lb. per head per day, on silage, but 2-1-3lb. per head per day on roots and hay-chaff; and in the 60 days, April 2 to June 1, the gain on silage has been 3lb. per head per day, and on roots and hay 2-1-3lb. per head per day. This is so contrary to a wide experience elsewhere, that critics challenge the experiment as vitiated by the stoking of the animals with too large quantities of the wet sour silage, or the giving of cotton cake as an astringent food at the same time as the silage, which is also astringent, or to the manner in which the food has been supplied. This will be duly sifted, no doubt, by the Basilage Commission in Parliament-street.—*The*

RHEA-RAMIE (CHINA GRASS) SUPPLY COMPANY, LIMITED.

UNDER this title, Messrs. G. W. H. Brogden and Co., as patentees of the Favier-Fremy processes, are promoting a Joint Stock Company with a capital of £200,000 in shares of £50 each, with the object of ensuring to manufacturers a regular supply of Rhea-Ramie (China grass) ready for spinning, rendering this country independent of the importation of flax and hemp from all sources except British colonies and dependencies. Our readers will recollect that in the early part of last year, a draft prospectus of the Johore Rhea Company was privately circulated, its object being to purchase 20,000 acres of splendid land in Johore on which to cultivate the fibre, and this project has been merged in the larger one of the China Grass Supply Company. The operations of the company as at present contemplated comprise—

No. 1—The purchase of ribbons where they are required in preparing the flax for manufacturing purposes, or otherwise.

No. 2—The ungumming in this country, elsewhere, by the Fremy-Urban, or other process, of ribbons so purchased or produced by the company's agents and licensees, converting the same into flax for the manufacturer.

The cultivation of land in Johore and Venezuela, and granting leases to the Chinese and Natives, and subsequently purchasing their produce of rhea, converted into ribbons.

No. 4—The granting licenses in the numerous colonies and dependencies of Great Britain. A license has already been granted to the Glenrock Company, Limited, for the South-East Wynnad. Negotiations are also progressing for the whole of India, Ceylon, and Mauritius.

We understand that the Manchester manufacturers have taken up the enterprise very heartily, and that of the 4,000 shares at £50 each, constituting the capital of the company, not more than 1,000 shares will be offered to the public. Mr. Casper, a partner in the firm of Messrs. Brogden and Co., recently delivered a lecture in Manchester on the subject, under the presidency of Mr. J. H. Hutton, chairman of the Chamber of Commerce, and the liveliest interest was displayed by the audience, which consisted almost entirely of mill-owners, merchants, &c., engaged in the textile industry. Mr. Casper explained at some length the nature of the plant, dwelling upon the ease with which it can be propagated and grown, and explained that large blocks of land specially suitable for its growth had been secured in Johore and Venezuela. A large portion of the land in Johore lay on both sides of a river navigable to the ports of Johore and Singapore at all seasons, and there were six crops a year. The delay which had taken place in the popularizing of the fibre arose from the difficulties and expense attendant

on its treatment to prepare it for use, but processes had somewhat recently been discovered which removed this difficulty, and now the fibre could be delivered chemically pure, ready for spinning and dyeing. From the date the plant was cut off until it was delivered to the manufacturer a week need not elapse, and the company, if formed, could insure a supply of at least a thousand tons a month. The material could be sold down cheaper than any present one—flax, cotton, or hemp—and it had qualities infinitely superior to any of them. It lent itself to almost any purpose, being on the continent made up into all sorts of things, and it was remarkable alike for strength, for delicacy and for finish. Some people had said that it would not take dye, but on the table were a number of samples which had been dyed in Manchester. Those who were moving in this matter had secured some thirty square miles of land, and had acquired very valuable concessions and privileges. What they wanted now was money to enable them to cultivate the plant, and to the company which it was proposed to form, Sir Joseph Lee had promised to subscribe.

We have from time to time published information as to the progress made by Mr. Minchin in the cultivation of Rhea on the Glenrock Company's estates, but we are glad to find the success of the experiment fully confirmed by Mr. Jennings, the secretary of the company, in a letter to Messrs. G. W. H. Brogden and Co. wherein he says:—

"Beginning in May last with about 2,000 plants by means of root and stem cuttings, and separation of roots, our manager, Mr. J. W. Minchin, has been able to report that in December he had increased his stock to over 300,000 plants, hoped by the following monsoon to have about 200 acres planted. Nothing could have been more satisfactory, such a result of a single season's operations. Of course, everything has been sacrificed to propagation, as a low have been allowed to mature; as soon as possible, they given up and divided, and in this way a single plant, such people produced thirteen strong-growing cuttings. The system of evidently suit the plant admirably, and during the British a portion of the acreage under rhea will come strained to mature stems will be decorticated by steam, and was received home to test the commercial value of the new fibre already

"You will also be pleased to learn that five miles from Ning to take a lively interest in rhea, could be known to many willing to furnish with our plan of private property, but by which means we hope to extend the plant to the officials. I think you may now accept it, which led to the his existence to the successful cultivation of future trouble. And if the subsequent try 1883 must have been to equally successful, the result from millions of India and lucrative to those engaged in good proof of the plant's value, English paper.

CHINA GRASS, OR RAMIE, CULTIVATION.

As the season is now approaching for the collection of the year's crop of stems on new plantations, it may be as well to point out to growers the machine for the extraction of the fibre is required to prepare it for the market. The selection of the fibre for trade purposes may be continued daily throughout the year, with only a short interval of rest in the winter months, in tropical or sub-tropical plantations, or from June to October in more northerly latitudes.

All that is needed is to collect the stems as they attain a standard length of three feet six inches. The women and children on the estate may cut them from the groups of growing plants as they attain this size; and as these newly cut stems are very succulent, they can be readily divested of their leaves by drawing each stem through the closed hand, and then, by simply inserting the thumb nail between the green bark and the stalk, about the middle of the stem, the bark containing all the available fibre can be readily peeled off. The now useless peeled stems can be thrown in a heap to be reduced to ashes by setting them on fire when dry, and this valuable fertilizer can be heaped up about the roots of the growing plants, or it may be covered with mould to swell the manure heap. The strips of thin bark must be carefully dried in the morning sun, or hung up during the night in light bundles, for if they are exposed to the scorching mid-day rays, the gums and resins in which the delicate fibre is involved coagulate and render their fibre brittle. Too great heat or too rapid drying has almost as injurious an effect on the fibre as the absurdly fatal plan of boiling the stems—to free the bark—would have, which has been so stoutly advocated by those who are so utterly ignorant to the rational mode of treatment of so costly a product.

To boil a stem of rhea with a view to removing the bark has the same injurious effect upon the natural gums and resins of the plant that boiling has upon the albumen of an egg—that is to say, it renders the pellucid liquid in which the fibre floats quite opaque, as we are familiar with it in the white of egg. But the fresh juices of the plant must become discolored by the brown coloring matter contained in the bark, subjected to the action of hot water, these coagulate, and the result turns to a dull black colour, and the fibre that has undergone this needless treatment cannot be continued. All subsequent attempts by chemical treatment to eradicate

this mill was only completed too late in 1884 to crush any cane during the season.

A few miles distant is the property of Messrs. Wilson Brothers, at Denba, whose mill was set to work during 1884. Upon the other side of the island the Colonial Sugar Refining Company are opening up a very large estate for the Auckland Sugar Refining Company, which is as yet only in an "embryo" stage. Higher up are the fine properties of Panang, owned by Dr. Chalmers, at work since 1882, with most satisfactory results; and Ellington, the estate of the Hon. J. H. Laefu, whose machinery was not completed until the beginning of 1885.

In the island of Mango, the Mango Island Company opened their mill during the season of 1884, and on Taviani are situated the plantations of Messrs. Billyard and Co., which got to work during 1883. That all of these establishments have not fulfilled the somewhat exalted expectations of those interested during the first year of their existence, and that one marked by so disastrous a fall in the price of sugar is more than probable, especially as the original estimates were in most instances largely exceeded, but they are all at work during this season with good prospects of success so far as the crops are concerned. Let other auspices be never so favourable, the essence of success lies in competent administration, which unfortunately in several instances has not characterized the direction of estates in Fiji. Persons undertook the formation of plantations and erection and management of mills without the least knowledge of the business. Ignorant of the country and language and the organization of labour, too conceited to profit by the advice of those who possessed the requisite practical experience, they squandered the funds entrusted to them, and were themselves the true cause of the financial difficulties, which they would attribute to the inefficiency or obstruction of the Government, or to any cause rather than the real one, viz., their own incompetence.

Turning to the labour question. All those persons best acquainted with the Fijians in their own country are agreed that they cannot be relied upon as the permanent and sole source of supply for the steady regular work of a plantation, but notwithstanding the objections alleged by your correspondent to be opposed by the Government, many hundreds of them are still employed under longer or shorter terms of engagement, and are very valuable as a supplementary labour. For some years past owing to the heavy demand for Polynesian labour for Queensland, Honolulu, and elsewhere, the supply from the islands of the Pacific has failed, not only in quantity, but also as to quality, which has deteriorated very seriously; consequently the mortality among these people during the first few months of their engagement has been so great as to be repugnant to the sentiments of humanity, and also to largely enhance the average cost of their introduction in the country. When acclimatized they are most efficient hands, either in the field or in the mill, and are excellent amongst machinery.

Failing these sources, the importation of coolies from India was begun by the much abused Sir A. Gordon, who, profiting by the experience of Mauritius and West Indies, where their labour had been productive of the happiest results, established an agency in India for their introduction, under Government supervision. At first the old planters, full of ignorance and prejudice, obstinately refused to employ them; now, however, they are gladly accepted under a five years' indenture, and several thousands are now working most satisfactorily. The cost of their introduction has been reduced, and in 1884 did not amount to more than £20 per head, and will be brought even lower. Last year, too, an ordinance was passed allowing the original cost of their introduction to be spread, over the whole five years, a great boon to smaller planters, and one that it is intended to further extend in the future. Being medically inspected before embarkation, there is very little sickness among them, and under a judicious system of piece-work, they give full value for the amount of money earned, and it need hardly be remarked here, that where a large number of hands are employed, everything depends upon a proper system of organization. And as regards the administration of the Immigration Department in Fiji, the utmost courtesy and desire to oblige the planters is displayed.

A very extensive acreage of land is now owned in fee simple by European proprietors, and a still larger area could be obtained on lease from the natives upon very reasonable terms. As to the suitability of the soil and climate of Fiji for the cultivation of sugar, tobacco, and other tropical products, one need only refer to the exhaustive report of Dr. Horne, of the Mauritius, who made a complete tour of the group about five years ago, and other equally reliable and independent authorities. Two rival lines of steamers run regularly between New Zealand, Victoria, and New South Wales, and a third firm has already entered upon the field, the competition between these colonies and Fiji has reduced freights to a very reasonable level; and, as for nine months in the year, fine weather prevails in these latitudes, the risks attending conveyance are at least no greater than in any other part of the world, a fact which is borne out by the low rates of insurance prevailing on shipments of produce.

Fiji, possessing as it does a rich virgin soil, a climate healthy and equable, where droughts and frosts are equally unknown, with fine harbours, and a supply of labour at least as cheap as is procurable in other parts of the world, and with the ever-increasing markets of the Australian Colonies within a few days' sail, offers a most favourable opening for the investment of capital; and the success of the sugar industry there is merely a question of efficient management, the more so as the production of sugar in Queensland must be seriously reduced by the labour laws, which have been made a political question to the very great detriment of the industry in that colony, and it can be asserted without fear

of disproof that the success which has so far attended those estates which have been under intelligent practical supervision is capable of very large extension.

Yours faithfully,

PLASTER.

THE COAL FIELDS OF BORNEO.

THE well-known geologist, the Rev. J. C. Tenison-Woods, has recently visited Borneo, and made a careful examination of the geological formation of that magnificent island, with especial reference to the existence of coal deposits, and in an interesting letter contributed to the columns of *Nature*, he points out that there are few countries of the world, except perhaps Eastern Australia, where coal is so extensively developed as in Borneo. Thick seams of coal are to be found in innumerable places on the coast and on the banks of the rivers. "In some of the streams of north Borneo," he says, "I have seen water-worn and rounded fragments of coal forming the entire shingle bed of the channel. In some places, again, there are outcrops with seams of good coal 28 feet thick. The coal formation is the one prevailing rock of the coast. It forms the principal outcrop about Sarawak. At Labuan, also, no other rock can be seen. Lining the banks of the Bruni River, he only saw picturesque hills of very old carboniferous shale. All the grand scenery of the entrance to the port of Gaya is made up of escarpment of coal rocks and at Kuching is the same.

"In Eastern Australia and in Tasmania, beds of coal of very different ages lie close together, and according to Mr. Tenison-Woods, it is the same in Borneo. Whether there is tertiary coal or not in the island he cannot say; but there is mesozoic coal and probably palaeozoic coal, and coals like that of Newcastle in Australia, whose position hovers between the true palaeozoic and the trias. The works at Labuan having been long since abandoned and the shafts having fallen in, Mr. Tenison-Woods found it next to impossible to explore the mine, but he asserts that there is plenty of coal and shale on the surface, and there are excellent sections on the sea cliffs close by. The whole deposit is very similar to the Hawkesbury sandstone of Australia. Now Labuan, as our readers are well aware, is a naval coaling station. Stores of coal are sent out from England at a great expense for the use of her Majesty's navy; and if the article could be got in the island, the enormous advantages are obvious. We think with Mr. Tenison-Woods that the deposits should be further tested. About fifty miles away to the south-east, at the mouth of the Bruni river, are rocks of quite a different character and much older. They are sandstones, shales, and grits, with ferruginous joints. The beds are inclined at angles of 25 to 45 degrees. They are often altered into a kind of chert. At Moura, there is an outcrop of coal seams 20, 25, and 26 feet thick. The coal is of excellent quality, quite bituminous and not brittle. The beds are being worked by private enterprise. Mr. Tenison-Woods saw no fossils, but the beds and the coal reminded him much of the older Australian coals along the Hunter river. The mines, he says, are of great value. They are rented for a few thousand dollars (by two enterprising Scotchmen) from the Sultan of Bruni. The same sovereign would part with the place altogether for little or nothing. Why not, asks Mr. Tenison-Woods, have our coaling station there? Or what if Germany, France, or Russia should purchase the same from the independent Sultan of Bruni? The Sarawak coal beds he did not visit, but a collection of fossils was kindly sent him. He recognised at once well-known Australian and Indian forms, such as *Phyllopora Australis* *Vertebraria*, forms which are entirely characteristic of the Newcastle deposits in New South Wales. The connection thus established between the carboniferous deposits of India, Borneo, and Australia is exceedingly interesting, and we are glad to hear that Mr. Tenison-Woods intends to publish all the observations he has made on the coal formations of Borneo and their included fossils."—*Planters' Gazette* (English Paper.)

FOREIGN BUYERS IN BERLIN.

THERE are at the present time in Berlin representatives of the great business concerns of the whole world, who are here for the purpose of making purchases and placing commissions. Besides the great firms of North America, there are buyers from South America, the most distant parts of Central America, England, Spain, and other Continental countries. Even Africa has sent buyers, who come from Port Natal. The purpose of these visits is the same—that of making purchases of those manufactures for which Berlin has become famous. There are particularly various branches of the textile and mineral industries, which profit greatly by the presence of so many foreign buyers. To these industries must, however, be added that of the artificial flower and leaf manufactures, an industry which in Berlin has reached important dimensions. Though ten years ago Paris monopolised this business, and though German traders had then to journey to the city on the

Seine for the purpose of supplying their wants in this direction, Berlin is now supreme in the market. As in all branches of trade, however competition is very severe, and the supply far exceeds the demand. It is said that one single manufacturer employs more than 1,000 work-people of both sexes in various prisons, and this employment of prisoners certainly makes the rivalry to be felt more keenly by some firms. The manufacture of fancy feathers of all kinds is continually extending in Berlin, and just as with artificial flowers it out-distances French competition. Fashion at present favours these articles. The export business grows rapidly, North America being an especially large buyer. The feathers in light colours made here are, by virtue of a peculiar process of preparation, preferred greatly to those of French manufacture. The inland, and particularly the export, business gives manufacturers satisfactory employment. — *Kuhlen's Review*.

GUANO.

By DR. A. P. AITKEN,

Chemist to the Highland and Agricultural Society.

The name guano is a Spanish word, signifying dung, and it was originally applied in this country to denote the valuable deposit, consisting chiefly of the excrement and carcases of sea birds which roost and nest upon the Peruvian shores, and feed upon the fishes that abound in the warm waters of that district. The remains of these birds had remained undisturbed for thousands of years, and formed deposits which in some districts were more than 100 feet thick. The first sample that arrived in Europe, was brought by Humboldt about the beginning of this century, but it was not until about the year 1840 that its great value as a fertilising agent was appreciated in the old world. From that time, and for more than thirty years thereafter, it was brought over in enormous quantities, so that the imports into the United Kingdom averaged about 200,000 tons per annum. The first imports were of a highly nitrogenous kind, yielding as much as 15 per cent of ammonia and sometimes more. These were deposits obtained from the Chincha Islands, a region in which rain is almost unknown, and where the heat of the sun is so great as to rapidly dry up the material and preserve its soluble constituents from deterioration. These rich deposits were soon exhausted, and attention was then directed to other parts of the coast, where deposits were found whose soluble nitrogenous materials had been to a greater or less extent washed away by rain and the spray of the sea.

During the last decade a great deterioration has occurred in the quality of the guano imports—the highly nitrogenous deposits are now exhausted, and the genuine Peruvian guanos now imported do not yield more than about 5 per cent of ammonia on an average. Corresponding with this decrease in ammonia there is a decrease of soluble phosphates, but the total phosphates are very much increased, so as to average upwards of 45 per cent. On some parts of the coasts where rain is abundant, the nitrogenous constituents of the guano are entirely washed away, and the result is what is called a phosphatic guano, containing from under 50 to over 70 per cent of phosphate of lime; but these deposits are also fast disappearing. Owing to the large proportion of soluble constituents in the original guanos, they were very powerful manures. Their effect upon the crops to which they were applied was simply marvellous, and it was with some difficulty that farmers were able so as to restrain their use as to prevent injury being done by too liberal application. Even during recent years, when the quality of the imports has so sadly deteriorated, a charm still lingers around the name of Peruvian guano, so that farmers are willing to pay a price for it which is much above its manurial value. The present imports of Peruvian guano, containing about 5 per cent ammonia and nearly 50 per cent phosphates, are, nevertheless, excellent manures, and capable of being used with greater freedom and safety than the powerful guanos of former years.

The charm surrounding the name of Peruvian guano has led manufacturers during recent times to manipulate the low-class guanos now imported so as to give them the appearance of the imports of former years. The deficiency of soluble nitrogenous matter is made up by adding sulphate of ammonia, and the result is that the mixture is able to fetch a price far beyond its intrinsic value. Sophisticated guanos of that kind are sold under various names. They are sometimes called 'standardised,' or 'equalised,' or 'prepared' guanos, and other names more or less occult are frequently applied to them; but under whatever pleasant name they may be advertised, the fact remains that they are low-class guanos, such as are now imported, to which sulphate of ammonia or some other highly nitrogenous stuff has been added. They are sometimes sold without any qualification, but that is simply a fraud. There are still some small residues of high-class ammoniacal guanos to be found in the country, but they are not likely to be bought at prices that would be profitable for ordinary farm purposes, and any one who buys a high-class guano should be careful to see that it is genuine. The composition of Peruvian guano, as now imported, somewhat resembles that of bones, only it is more active manure.

Dissolved guano has long been before the public, and the best kinds of it were no doubt very excellent manures. They were sometimes sold as 'ammonia-fixed guanos,' and at the time when high-class guanos were being imported in a somewhat wet state,

the addition of sulphuric acid to them was a very sensible practice; but nowadays the amount of ammonia in guano is too small and of so fixed a character, that it requires no artificial fixing. The dissolved guano of the present day will contain about 2 or 3 per cent of ammonia, and of course a large proportion of soluble phosphate. If it contains a high percentage of ammonia, it is most probably a mixture, and it may be a dissolved compound containing no genuine guano in its composition.

The name guano has now come to be applied to various substances which have no claim to the title. Fish guano is one of these. It consists of the dried offal of the fish-curing yards, or some other preparation of the dried substance of fish. Its phosphatic and nitrogenous matter are both insoluble, and it forms a very slow-acting manure. The fine form in which many of these fish guanos are presented in the market leaves nothing to be desired. They are very attractive manures, and it is unfortunate that owing to their oiliness and other causes, they are slow to decompose in the soil, and are very disappointing in their results. Such manures would be greatly improved by being dissolved, but the large amount of organic matters they contain, makes it impossible to dissolve them to any great extent. Any manufacturer who should discover a method for quickening the action of fish manures would bestow a boon on agriculture, for the utilising of fish manures is the great means of restoring to the land the enormous amount of nitrogenous matter which is constantly being carried down from the land into the sea.

Frey Bentos guano is another manure which has had an erroneous name applied to it. It has no claim to be called a guano, as it consists of the offal of animals slaughtered for the sake of their marketable products, such as extract of beef, hides, gelatin, &c. This substance, like the former one, is of little use when applied alone; but, nevertheless, it forms a very useful ingredient in a dissolved manure when it has really been dissolved, and not simply mixed with it in its insoluble form.

There are many other manures sold under the name of guano that ought never to have had the name applied to them, and the sooner they are sold under legitimate names the better, for guano is a name which applies only to excrementitious substances which have passed through the digestive system of an animal.

Bat guano is the excrement of the bat, and in that respect may be considered a guano. It contains much organic matter, but is low in phosphates and ammonia.

Ichaboe guano is a genuine guano of recent formation. It is a highly nitrogenous manure, but much of its nitrogen is in the form of feathery material, which comes only very slowly into action. This also is a substance which would be improved by being dissolved but it cannot be dissolved to any great extent. It is much sought after as a manure, and when applied early, is a good constituent in a mixture which is intended to nourish a crop whose life is of long duration. As it is a recent deposit, and restricted in its area, the supply is very limited, and much behind the demand.

The genuine phosphatic guanos, such as Maldon, Baker, and Mona guanos, are simply phosphatic manures having the analysis of various kinds of mineral phosphate; but they possess one great advantage over these in having been at one time dissolved to a considerable extent, and they are in some measure composed of precipitated phosphates, which, although it is insoluble in water, is nevertheless rapidly dissolved by the acids in the soil and the solvent action of the roots of plants. — *North British Agriculturist*.

DISSOLVED BONES.

By DR. A. P. AITKEN,

Chemist to the Highland and Agricultural Society.

Bones coarsely crushed had not long been in use as a manure, before it was found that their efficacy was greatly enhanced by dissolving them to some extent in sulphuric acid. That was a very important discovery, which not only marked an epoch in agriculture, but gave rise to a new industry, which has now assumed large proportions, and indirectly had a beneficial influence on the whole manufacturing trade of the country. Its immediate effect as regards the use of bones was to transform them from a slow into a quick-acting manure, capable of being applied with advantage to crops whose period of growth was of short duration. It enabled farmers very considerably to reduce their expenditure in the purchase of bones, for it was found that one bushel of bones when dissolved with acid produced a far more immediate and powerful effect upon the crop than two or three bushels of crushed bones; and as the price of bones rapidly rose in proportion as their use became more general, this discovery was a great boon to agriculture. Farmers bought sulphuric acid and dissolved the bones themselves, but as this was a troublesome operation, and not unattended with danger, a class of men arose who made it their business to dissolve bones and supply farmers with the finished article. This was the beginning of the manure manufacture, and it was not long before it was found that superphosphates and all other phosphates were capable of being dissolved in a similar manner so that superphosphates and other dissolved manures came rapidly into existence. The great promoter of this new industry was Sir John Bennett Lawes, who not

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA:—SATURDAY, AUGUST 1, 1885.

[No. 31.]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING JULY 22, 1885]

General Remarks.—Rain is reported from the Madras Presidency generally, and prospects, which are elsewhere fair, have much improved in Bellary and are more favourable in Anantapore. More rain is still wanted for the crops in parts of Bellary, Channarayana, and Tanjore. In Mysore slight rain fell in most parts of the State, but more is required. Prospects are uncertain in Kolar and in the lowlying tracts of the Shimoga and Kadur districts; elsewhere in the province prospects are, on the whole, favorable. In Coorg there has been a good deal of rain, and prospects continue favourable.

Good rain has fallen throughout the Bombay Presidency, and prospects have greatly improved. More rain is required for sowings in Khandesh and in the Panch Mahals. *Kharif* sowings are in general progress. Rain has fallen throughout the Berars, in Hyderabad, and the Central India and Rajpootana States, and prospects are, on the whole, very favourable, though in Marwar, considerable anxiety is said to prevail on account of the scanty rainfall. In the North-Western Provinces and Oudh, in the greater part of the Punjab, and in the Central Provinces rain has been general, and *Kharif* operations are in active progress.

Good rain continues to fall in Bengal, and agricultural prospects are favourable in all districts. The autumn crops and sugarcane promise well, except in some places where they have been damaged by floods. Harvesting of early rice and jute has begun in parts of Northern and Eastern Bengal, and the transplanting of late rice is going on well. Good rain is reported from Assam, and the state and prospects of crops continue favourable.

In British Burmah the weather is seasonable; and ploughing, sowing, and transplanting are in general progress.

The public health is fairly good in most provinces, and prices are generally stationary, except in the Punjab, where they are rising in Ferozepore and Peshawur. In Bengal prices are still high.

Madras.—General prospects fair, much improved in Bellary and better in Anantapore.

Bombay.—Good rain throughout the presidency. Prospects greatly improved; more rain required for sowing in parts of some districts especially Khandesh and the Panch Mahals; rice transplantation progressing; standing crops injured by insects in parts of Upper Sind Frontier; fodder is scarce in parts of Nasik and Ahmednugger. Cholera in parts of seventeen, and fever, small-pox, and cattle-disease in parts of eight districts.

Bengal.—There has been general rain during the week, and agricultural prospects are favourable in all districts; more rain is wanted in Moorshedabad. Autumn crops and sugarcane are generally very promising, except in a few localities where some damage has been done by floods; transplanting of late rice progresses well; harvesting of early rice and jute has begun in parts of Northern and Eastern Bengal; in spite of the present good prospects of the crops, the price of rice remains high and shows no signs of falling. General health continues to be fair. The earthquake on the morning of the 14th instant was felt all over the Lower Provinces.

N. W. Provinces and Oudh.—Rain has been general throughout the provinces; in Aligarh the fall has been extremely heavy, causing damage to crops. *Kharif* operations in progress, and prospects seem favourable. Markets are well supplied, and prices fairly steady. Public health generally good.

Punjab.—Rain in most districts. Slight cholera in the Goorgaon district, in the Channarayana of the Lahore district, and in the city and cantonment of Rawul Pindus; elsewhere, health is generally good. *Kharif* sowings in progress. Prices of food-grains generally stationary, rising in Ferozepore and Peshawar districts.

Central Provinces.—Good rain with favourable weather for agricultural operations. Cholera continues in Chhattagurh and in two other districts. Prices steady.

British Burmah.—Cholera severe in four, and slight in four, districts; small-pox slight in one district, elsewhere public health good; cattle-

disease severe in two and slight in three districts, elsewhere health cattle good. Ploughing, sowing, and transplanting progressing. Rain seasonable.

Assam.—Weather warm. Some damage done to *amahi* and *mirati* crops by insects; transplanting of *am* crops nearly finished; ploughing for *sali* crops progresses; prospects of tea favourable. Common rice 13½ muns per ruppee. 8 deaths from cholera from Lakhimpore and 1 from Hailakandi reported; general health otherwise good.

Mysore and Coorg.—Coffee and cardamom crops in good condition. Prices of food-grains slightly fallen. Prospects of season and public health good.

Berars and Hyderabad.—Standing crops good. Cholera continues in some places, otherwise general health fair. Prices—wheat 14½, coarse rice 12½, white *jeer* 19, yellow *jeer* 23, and *bar* 15½ seers per current sicca ruppee.

Central India States.—Weather cloudy and warm; health and prospects good.

Rajpootana.—Good rain throughout the districts; tanks and wells fair. Fever prevailing; health otherwise good. Sowings continue. Prices stationary. Weather hot and cloudy, with high winds.

Nepal.—Prospects of crops good. Cholera continues.

Letters to the Editor.

MANGOES.

TO THE EDITOR.

SIR,—Having had some years' experience in Bengal as an agriculturist, during which time a large number of plants raised from the seed of grafted mangoes passed through my hands, I can assure your correspondent "C. R. V." that the trees of which he complains will bear fruit. Let him to try the following simple method:—Loosen the soil round the roots about six inches, and remove the old, and fill up with fresh earth. Having done this, sprinkle a basket-full of pigeons' dung (about a seer) round the roots; then water regularly for a week. This will, I think, meet the case. If, however, pigeons' dung is not procurable, mix cow-dung with fresh lime, in equal proportions, and use as recommended above.

HEM CHUNDER DUTTA.

July 26, 1885.

MANGO INSECT PESTS.

TO THE EDITOR.

SIR,—With reference to the question put by your correspondent regarding the larva of some insect which destroys the mango fruit, I regret to say I have not studied the habits of this insect, as in the North-West and Oudh mangoes are not often injured in this way, but peaches are. I think it probable that it may be a moth which deposits its eggs in the flower, and when they hatch they work their way into the young fruit, as it sets, and grow with it, and ultimately emerge from the ripe fruit. If some of the mangoes containing the larva are sent to the Director of the Entomological Department of the Indian Museum, Calcutta, he may take steps to secure the perfect insect, when it emerges, and throw some light on its habits, whether a moth or a beetle, which would be a great step. I might also suggest that some one should, during the flowering and setting season, endeavour to observe what insects—moths especially—visit the mango flowers, either by day or after sunset. They might be able to observe with a large magnifying glass what they are about if they see any. As long as only a few

mangoes are spoilt by these insects, it does not much signify, but when the fruit of a whole district is thus destroyed, it is time to study the cause and search for some remedy. If the insect deposits eggs on the young ovary, either before or after setting, some insecticide syringed over the young fruit, when set (not while the flower is in pollen) might destroy the eggs or young larvae before penetrating the young fruit. Tobacco juice in water is often used for destroying insects on plants; caustic ashes in water, and other solutions might be tried. Of course, the insecticide should not damage the fruit also. But the first step is to get a clue to the natural history of this insect whatever it is. As it destroys so much fruit, there can be no harm done by making some experiments with a garden syringe or pump, and noting the side of the tree, or the whole tree on which experiments have been tried. Some of the very young fruit should be examined with a good gnawing glass to ascertain whether there be any evidence of a hole or broken surface, through which the minute larva may have crept in, and also to cut open the very young fruit and explore it with a glass in every way. In short, to obtain a clue how this insect gets into the mango fruit, and when, and then endeavour to work out its history. If the study of entomology has any uses at all, a great one is to discover a remedy against the worry insects give us, and the loss they entail. But until we learn something about their "manners and customs," we may be only wasting time in fruitless attempts to circumvent them. Another observation is worth making—are all the mangoes in the districts named attacked by this pest? If there be some which are not, then the seeds of those only should be sown there, and grafts from those only taken. The extreme dampness of the climate of those districts may facilitate the ravages of this insect. Other kinds from up-country, such as the solid fleshed ones, *safila*, *dhadania*, and others might be also tried there. There may be a hundred dodges by which one can oppose these little pests. Depend upon it, there is nothing worth doing in this world which can be done without trouble, and if a thing is worth doing at all, it is often worth one's while to take a great deal of trouble about it.

E. BONAVIA, M.D.

ENSILAGE vs. GREEN FODDER.

TO THE EDITOR.

SIR,—As you have been good enough to publish my hints on ensilage, as also to comment upon them in another part of your valuable journal, I venture to send you a letter in support of the theory which you question, viz., that ensilage cannot be so nutritious as the fodder from which it is made. I shall first quote Dr. Aitkin's remarks in the "Transactions of the Highland and Agricultural Society of Scotland." After admitting that some coarse kinds of fodder, such as maize, when put into a silo are rendered softer or more palatable, he goes on to say that this cannot be said of clover, vetches or sweet grasses—"any change which they may undergo in a silo cannot be of a constructive or elaborative kind, but rather of a destructive kind. Construction is the work going on in the body of the living plant, the materials out of which its tissues are made are derived from outside of it, from the soil and from the air, and the moving power which builds these tissues up is the energy of the sun's rays. When the plant is cut down, and crushed into a dark pit, any changes which can occur are not those of building up but rather of breaking down." Experiments by the late Dr. Voelker, by Weiske in Germany, and by Professor Kinch at Gloucester, all show that there is not only loss of solid matter during fermentation in a silo, but that the albumenoids or flesh-formers are partly degraded into amides-amido acids, and other forms of nitrogenous matter, which are less nutritious than the true albumenoids found in the original fodder from which the ensilage was made. In some experiments made at Washington by Mr. C. Richardson, chemist to the Agricultural Bureau in America, on silage made from maize, it was shown that the percentage of non-albumenoid nitrogen in the silage was double that found in the green maize. I do not understand how the conversion of starch into sugar by fermentation enhances the feeding value of fodder: for the same process is effected by the saliva of all ruminants while they chew the cud. In conclusion, I should be glad to hear the name of any chemist who holds that pitting fodder improves its feeding value.

D. B. ALLEN.

Camp Behar, July 26, 1885.

Editorial Notes.

THE Financial Department of the Government of India notifies that in the calendar year 1886, there will be offered for sale 54,000 chests of Bengal Opium, at the rate of 4,500 chests each month of the year. Of these 4,500 chests, 2,350 will consist of Patna, and 2,150 of the Benares drug.

THE system of ensilage has been found to render even nettles fit for food, as we learn that Vicomte Chezelles, the French nobleman who gave evidence before the Ensilage Commission, is accustomed to place large quantities of nettles in his silo, and states that the silage they yield is not only highly nutritive, but that the stock eat it readily.

THE quantity of tea exported from China and Japan to Great Britain, from the commencement of the season to the 2nd of July, was 49,170,477 lbs., as against 49,257,920 lbs., exported in the corresponding period of last year. The exports to the United States and Canada during the same period were 6,790,605 lbs., as against 7,654,678 lbs.

THERE is no improvement visible in the trade of Australia during the month of June last. With reference to the exports from Melbourne, it appears that, but for the large shipments of gold, the returns would have been much more unfavourable. In fact, as they now stand, the exports show a decrease of £192,567, and the imports a decrease of £65,240, when compared with those of June 1884.

THE Gold Mines of Southern India are apparently doing good business, for we learn that the *S. S. Manora*, which arrived in Madras roads the other day from London, landed three miners—one for the Nundidroog, and two for the Mysore Gold Mines, together with a lot of machinery, &c., for the latter mine. This increase in the staff of miners is owing to the extensive work being carried on by the Chief Superintendent, Captain Plummer.

WE have much pleasure in publishing a letter from Mr. D. B. Allen on the respective merits of ensilage and green fodder. Want of space prevents our noticing the subject at length this week; but we hope to do so in our next issue. Meantime, we shall be glad to receive and publish the opinions of other agriculturists on the important point raised, as to whether fodder, when stored in a silo, gains or diminishes in nutritious constituents. The subject is an important one for India.

MR. BUCK, the Secretary in the Revenue and Agricultural Department, was to have left Simla on the 26th ultimo for Bombay. It is understood that his visit is connected with Exhibition matters. Before he left Simla there was to have been a conference of the heads of the Agricultural Department, Messrs. Fuller, Smeaton, and Crosthwaite, who had already arrived in Simla, and the other Agricultural Directors who were expected. A variety of subjects were to be discussed, and some questions in connexion with the work for the London Exhibition were to be settled.

WE have before drawn attention to the excellent effects of using a kerosene emulsion as an insecticide. The *Farmer's Review* tells now that Professor Cook, of the Michigan State Agricultural College, gives his preference to the kerosene and soap emulsion over every other kind of insecticide, when dealing with the bark louse. He makes it as follows: One quart of soft soap to one gallon of water brought to a boil, and one gallon of kerosene added to each twelve gallons of soap solution. In order to apply this, some kind of a force pump is needed.

We understand that Colonel Le Messurier, Consulting Engineer to the Mysore Government, is collecting and arranging exhibits to represent Mysore at the Colonial and Indian Exhibition. They include specimens of sculpture from Billagavi, Halebede, and Somnathpore. These are ancient, and illustrative of the old art of decorating temples. Specimens of wool fabrics will be sent from Kolar, Bevingari, and Bangalore; woollen mill carpets from Bangalore; and jail cotton fabrics from the Maharaja's spinning mill, Mysore. Jewellery will also be very largely represented.

.

A CONTEMPORARY has heard by wire that a Conference of the Directors of Agriculture of the North-Western Provinces and Oude, and the Punjab, was held at Simla a few days ago to discuss the question of establishing an Agricultural College at Dehra, for the improvement of the breeding of cattle, and promotion of veterinary science, with a view of preventing the ravages of disease, and consequent destruction of the cultivator's stock. These are questions of much importance, and it will be interesting to read the proceedings of the Conference, as recorded on the occasion, which we hope will be supplied to the Press for the information of the public.

.

A BOMBAY contemporary says—With regard to a resolution which appeared in our columns the other day, concerning the growth of arrowroot in this Presidency, we hear that the cultivation of arrowroot has been known in the Concan for nearly half a century. Indeed, it is supposed to be indigenous in the Concan. It was for many years grown at the Ratnaghorry jail, and manufactured there, and for all we know, it may be still. We believe it was for some time supplied to the hospitals. The Director of Agriculture is not strictly accurate when he speaks of "wild arrowroot at Mahableshwar;" it has become wild, but it was introduced from the Concan.

.

At a meeting held recently at Exeter Hall, London, under the auspices of the East Indian Association, it was stated that "much dissatisfaction exists among Indian agriculturists as to the system of taxing their improvements on land. The limitations now imposed by executive orders are said to still leave immense and altogether arbitrary powers in the hands of the Settlement Department, and the new measure for the regulation of assessment leaves the cultivators' position hopelessly insecure, and without adequate security. Agricultural improvement on any scale is said to be thus nearly rendered impracticable, and that the Government must sooner or later realise that these re-settlements and arbitrary revisions of assessment are the greatest of all obstacles."

.

An enterprising man is a good pioneer, and although the Temperance Societies may not agree with us, yet we must congratulate Mr. Whympere on his new venture. This gentleman is proprietor of the Murree Brewery, and has established breweries in several parts of India. He is now, however, we learn, finding an outlet for his energies in Ceylon, and will soon be making beer at Nuwera Elyia. The plant for the Ceylon concern unfortunately lies at the base of the Berlen rocks, having been shipped in the ill-fated *Eldorado*; no time, however, was lost in telegraphing for another supply of plant, which has since reached Colombo, and will be erected under Mr. Whympere's personal supervision. It is expected that the first brew will be ready by October.

.

Up to the 31st May last, the Guarantee Fund of the Colonial and Indian Exhibition had reached £189,050, of which the Government of India subscribe £20,000, the Canadian Government £10,000, the Governments of New South Wales, Victoria, and New Zealand each £5,000, and the Government of South Australia, Queensland, and the Cape Colony each £2,000.

It will be observed from these figures that India contributes the largest amount. She ought to be very well represented. But there is some fear that our anticipations may not be realised in this respect, as the management is entirely in the hands of Government officials. It is the trade that is most interested in this Exhibition, and we cannot help thinking that

the Government of India is making a mistake in excluding all private interests from the management. The mistake made in the Calcutta Exhibition was just the other way, but in that case, there were too many "cooks," who "spoil the broth."

.

We see that Indian tobacco is to be brought prominently to the front at the forthcoming London Exhibition of 1886. A letter has been addressed by the Revenue and Agricultural Department to all Local Governments, stating that a proposal has been made by Messrs. H. S. King & Company, the official Agents for the Indian and Colonial Exhibition, that they should be allowed to open in the Exhibition a separate "cigar and tobacco room," in which can be exhibited samples of raw and manufactured tobacco from all parts of India. Messrs. H. S. King & Company offer to place one or more attendants in charge of this room, who will furnish sample cigars, price lists of the different makers, weights of the cigars for computation of duty, &c. They will also take charge of consignments from the makers, and will take orders, either in large or small quantities. They undertake to represent all the manufacturers impartially, and without preference, and to make the increased popularity and greater demand for Indian cigars their special object.

.

This proposal has commended itself to the Royal Commissioners, and has been referred by them for the consideration of the Government of India, by whom it has been formally approved. Small samples of Indian cigars and tobacco, both raw and manufactured, will be exhibited in the Imperial Courts of the Exhibition; but the space there assigned to them is necessarily limited, while it is impossible for the Government to give any facilities for trying them, such as will be offered in the proposed tobacco room. Under these circumstances, it has been decided that the Government exhibit of tobacco should be kept within limits sufficient to represent this important product in its principal branches. It is therefore strongly recommended, in the interests of the Indian tobacco trade, that consignments of cigars and tobacco, if sent in large quantities, should be made to Messrs. H. S. King & Co., or their Indian Agents, Messrs. King, Hamilton and Co. of Calcutta; King, King & Co. of Bombay, and Arbuthnot and Co., Madras. Much stress is laid on the desirability of consignments of tobacco and cigars being sent, if possible, some months before the Exhibition opens. Indian cigars, it is observed, nearly always arrive from India so wet as to be unfit for early use; and if passed through the Custom House at once before they have had time to dry, the duty payable is greatly enhanced by the superfluous damp which they contain.

.

We see that Mr. Bosworth Smith, the newly appointed Mineralogist to the Government of Madras, has been making explorations in parts of the Nilgherries round Ootacamund and other places. It cannot be said that his enquiries have resulted in any important discoveries, but he seems to have done some good work during the short time he has been out. He has found small specimens of iron, traces of copper pyrites, and galena in quantity near Ootacamund, as well as of gold—the last named metal in such small quantities as to almost preclude the hope of getting at it with any prospect of gain. He also found a deposit of kaolin, which he thinks may possibly be used for the manufacture of porcelain. It would, however, require much cleaning and careful preparation before it could be thus utilized, as it was seen to be discoloured by iron oxide, and contains much silica grit. But Mr. Smith proposes to carry out certain experiments with a view to determine the economic value of the deposit. Mr. Smith seems to have exploded some of the statements contained in the District Manual, so far as it relates to the Nilgherries. One statement, that large masses of iron existed in the district has so far been found chimerical, that there was not a sufficient quantity to pay for smelting operations, except in small native furnaces. Another statement, that copper pyrites did not exist in the Nilgherries, has been proved to be fallacious, as many traces, and some specimens, were found. We hope Mr. Smith will dissipate many other fallacious statements in the District Manual aforesaid.

FIBRE-YIELDING plants will always be in demand; if they are not suitable for the manufacture of fabrics, they can always be utilized in the manufacture of paper; and although varieties of known fibre-plants are many, yet every addition to their number is viewed with interest and satisfaction by the trade. Recently in the Madras Presidency, they have been experimenting with the fibre of a plant called *Helicteres Isora* (vernacular, *Kol-nar*.) The unsatisfactory result obtained was due more to an ignorance of the method of preparing fibre for the manufacturer's loom than anything else. It appears that 500lbs. of this fibre was supplied in April last by the Forest Officer of Ganjam to the firm of Messrs. Arbuthnot and Co. This firm has reported that the fibre was not properly prepared, being hard and quite black, and unsuited for manufacture into bags. It was found that the fibre had not been put through the usual steeping process, when stripped from the plants, but appeared to have been merely sun-dried. There were several varieties found in the consignment of 500lbs., old and young fibre having been mixed together, and the plants from which it was taken were found to have been cut at different times. Under these conditions, it was scarcely possible to obtain satisfactory results. There was, however, one quality which was found to be superior to Berhampore jute, and it was thought that if the plant was cut at the proper time, and put through the usual process of steeping, it would yield good fibre for making bags.

The collection and transport charges amounted to Rs. 104-13-7 for 500lbs., which means Rs. 409-11-7 per ton. This rate is so high as to render the cost of collecting at Ganjam prohibitive. This is the second trial of the kind made with this fibre. The first trial was made some time in 1884, and the fibre was collected in the Kurnool district. The cost of collection and transport by rail on that occasion amounted to Rs. 53-12-0 for 1,500lbs., or at the rate of Rs. 80-4-3 per ton. Although this result is somewhere near the mark, it was at the time considered unfavourable. The lowest quality of jute can be had at Rs. 2-15 per maund, or, in round numbers, Rs. 82 per ton. The *Helicteres* fibre at Rs. 80-4-3 per ton is not so very bad; but as its quality is inferior to jute, it would not prove remunerative to produce it at that rate for the market. There is, however, this to be said, that the trial was made under unfavourable circumstances; and until such time as a thoroughly satisfactory experiment is made, it would be premature to pronounce a judgment on the quality of the fibre. We find that it is intended to send a sample of 100lbs. of the fibre to the Secretary of State for India for valuation in the English market. This reference should settle the question.

A Local contemporary, referring to some of the principal revenue appointments which are to be abolished in the Madras Presidency, says:—"Last year the Abkari Department in the mofussil was amalgamated with the Salt Department, and placed under the charge of Mr. Bliss, the Salt Commissioner. It has now been decided that the Abkari Department in the town of Madras, hitherto under the charge of the Collector, shall be placed under the charge of the same gentleman. The Customs Department will also, probably, be placed under his charge, so that Mr. Bliss, like Aaron's rod, appears to have the capacity for swallowing up many others." There is, however, more beneath this satire than appears on the face of it. It is the bane of the service to saddle an officer with so many duties in addition to his own, that in his efforts to perform them all he is forced to lose sight of his legitimate duties, with the result that, instead of one department being efficiently managed, half-a-dozen are mismanaged. Whatever other attributes a civilian may be said to possess, it is certain he has not that of ubiquity. If he could, in addition to being ubiquitous, combine the attributes of Argus and Briarion, there might be a remote probability of a civilian managing half-a-dozen appointments at one and the same time.

We learn from a contemporary that the cattle fairs at Hissar and Jahazgar, held during the spring of this year, were both a success, not only as far as a large increase in the

number of cattle sent for sale at each fair, but also as to the prices realised. This latter is said to have been caused by a very large demand for them by traders coming from beyond the Jumna, and in one instance, Rs. 175 was offered for a single bullock and refused by his owner. With regard to these and other fairs, the Lieutenant-Governor has decided that, as the transfer of the management of cattle fairs to local bodies will soon be made, it will not be necessary, in future, to submit reports on them to the Local Government, unless there are any special points which call for orders. The fairs are now considered to be on a permanent and well-established basis, and generally nothing occurs from year to year which is likely to give rise to any new questions in connexion with them. In future, the fairs will only be noticed in the annual revenue administration report, and the only reference which need be made to Government will be in connection with applications for rewards, which at present require Government sanction.

It will interest our readers to know, on the authority of *Kuhlow's*, that the origin of weights and measures in England was derived from a grain of wheat; vide Statutes of 51, Henry III., 31 Edward I., and 12 Henry VII., which enacted that 32 of them, well dried, and gathered from the middle of the ear, were to make 1 pennyweight; 20 pennyweights, 1 ounce; 20 ounces, 1 pound. It was subsequently thought better to divide the pennyweights into 24 parts, called grains. William the Conqueror introduced into England what was called Troy Weight, from Troyes, a town in the province of Champagne, in France, now in the Department of Aude, where a celebrated fair was held. The English were dissatisfied with this weight, because the pound did not weigh so much as the pound in use at that time in England. Hence arose the term *Avoir du poids* which was a medium between the French and the ancient English weights. Avoirdupois weight was first made legal in the reign of Henry VII., and its particular use was to weigh provisions and coarse, heavy articles.

We note that the third edition of Dr. E. Balfour's *Cyclopaedia of India* has just been published in London. The first edition was published in 1858 in India, the second in 1873, also in India, and the years 1877-84 inclusive have been occupied in revising it for publication in England. Dr. Balfour, in his prefatory notice, says that the present edition contains 35,000 articles, and 16,000 index headings, relating to an area of 11,722,708 square miles, peopled by 704,401,171 souls. There is no doubt that the work is a most comprehensive one, and likely to prove most useful and interesting as a book of reference. It takes in a very wide field, for the author says:—"India in its ethnology, its flora and fauna, can only be fairly dealt with by embracing a wider area. This is the reason why the Cyclopaedia and my work on the timber trees include all Eastern and Southern Asia." The work consists of 3 volumes, embracing 3,628 pages; and the price—£5-5, although not high for a publication of this nature, places it beyond the reach of the average reader. We hope, however, that the publisher will see his way to producing a cheaper edition, so that it may come within the means of the masses.

The proposed Veterinary College Hospital at Bombay does not seem to find favour with the Municipal Corporation of that city; at any rate, that civic body is not willing to contribute more than Rs. 2,500, or less than one-eighth, towards the maintenance of the hospital. The Government of Bombay have addressed a letter to the Corporation, expressing Lord Reay's regret at the scanty sum allotted by the municipality towards this useful and beneficial institution. But his Excellency has taken the 'change' out of the municipality. With reference to a hope expressed by the Municipal Commissioner, that the Corporation may be allowed to "nominate ten scholarships," the Governor in Council expresses himself unable thus to allot the right of nomination to scholarships, which are to be granted only to picked men selected with regard to their personal qualities and future intentions, and which will be given as rewards to the candidates most successful in the

examination. The scheme provides for 15 free studentships, and the Governor in Council will be prepared to place three of these at the disposal of the Corporation on certain conditions, and a larger proportion in consideration of any additional contribution. We cannot, however, understand the necessity for these negotiations just now, as the College is only in prospective, the Government having declared itself unable to fulfil its promises of support for the project.

**

A home contemporary, commenting upon Agricultural affairs in America, says:—The agricultural situation in America becomes more gloomy every month. At the beginning of April the condition of the winter-sown wheat in the United States was represented by 77 in the returns of the Department of Agriculture. A month later it had fallen to 70, and at the beginning of June it has further declined to 62. This is the lowest figure which the department has ever had to publish for the prospects of winter wheat. The reports from the Farmers' Associations are even gloomier than the official statements. But making every allowance for the natural despondency over such untoward prospects, it is evident that the wheat crop of America will this autumn be one of the smallest and the least available for exportation of any recent year. 207,000,000 quarters is the presently estimated produce of the winter wheat, and 153,000,000 quarters of the spring wheat. This last looks much better than in some recent years, its present figure being 97. With such an estimate from the principal source of supply of our wheat trade, it is an indication of the extreme dullness of trade that there is not the slightest sign of an upward movement in the grain market. The collapse of the upward movement of prices at the time of the war scare has been so thorough, and the influence of the immense shipments of grain within the last weeks so marked, that the movement is still distinctly downward, and the price is now quite three shillings below the average of the low figures current this time last year. But the visible supply in America is now quickly diminishing, and the chances are that with the harvest, there will come some more activity in the wheat trade with rather higher prices for the farmer, on this side of the Atlantic at least.

**

We are told by a correspondent of the *Englishman*, who professes to be intimately acquainted with the Burdwan district, that matters are steadily improving amongst the people. We are unfeignedly glad to hear it, and hope earnestly that it is true. The rainfall has terminated of course their sufferings from the want of water which were very great, and we shall be glad to hear the report of the writer confirmed. Our confidence in his statements is not implicit, for we find him bringing the most monstrous charges against our native contemporaries, for the honorable interest they have shown in the condition of the people. He tells us positively, "as a simple matter of fact, that relief has been ample to allay the partial want from which the people are suffering; that there has been no neglect of the condition of the people; on the contrary, a most careful and scrupulous watch has been maintained, and at the first indication that matters were growing worse, the Government was prepared to extend the measures of relief." These statements are not, we fear, borne out by the facts. We notice them at greater length elsewhere, and also the unworthy charge which the writer makes as to the motives which have influenced our native contemporaries in the attention they have given to the circumstances of the people.

The usefulness of the *Sar Kanda*, or *Muny* plant, in the south-east of the Punjab is, according to the author of one of the recent settlement reports of that part of the country, hardly less than that of the bamboo and palm in other localities. The leaves, we are told, are used for thatching houses, the reeds being bound round the edges and across to strengthen the thatch. The reeds are also used for making furniture, such as chairs and stools, and for agricultural implements, such as trays and baskets, and the fronds-work of receptacles for chopped straw. The plant, farther, often affords the only pasturage available for cattle, and though the dry leaves are said not to be very fattening (a statement which may

be readily credited) they suffice to maintain the cattle in condition. The green leaves naturally yield greater nourishment; but they appear only when the plant is fired; and as reeds are seldom produced after the plant has been so treated, the villagers rarely resort to this process, except in the case of inferior plants. But the principal value which many possessors in the eyes of the cultivator lies in the inexhaustible stores of fibre which it produces ropes and string, without which no agricultural operations could be carried on, and no comfort would be found in their homes. In the autumn, the view is closed in on every side by the high flowering stems of the plant, and then is the chance for the wanderer to lead you a rare dance in search of his fiddlers. Of late years, the villagers have taken to selling the *sar kanda* of their lands, and many cases a very considerable income is realized from disposing of this natural product.

**

We take the following from *Kocher's*:—An investigation has been made by Mr. L. Marx to discover what country produces barley richest in protein (nutritious matter), he having for his purpose analysed more than 400 samples from the harvests of six years. The mean percentages of protein, as found by him, are given in the following:—

Russia	12.76
Baden	12.38
Sweden	12.97
Danubian Provinces	11.68
Brunswick	11.49
North Germany	11.21
Bavaria	10.76
Alsace	10.70
Hungary	10.62
France	10.55
Hesse	10.43
Wurtemberg	10.35
Denmark	9.91
England	9.69
Austria	9.61

Some of the Russian barley gave as high as 16 per cent protein; the maximum of Baden was 15 per cent, the minimum 10.60 per cent. Bohemia and England seldom exceed 10 per cent. Of 64 samples of Bavarian barley examined, gave over 12 per cent, the remainder under 10 per cent. The French barleys, those of Auvergne gave the lowest yields, those of Champagne and Burgundy being up to the average of Bavaria. The percentage of nitrogenous ingredients Hungarian barley varied more than in any other kind, the numbers ranging between 9 and 12. Thick-skinned grain is poorer in nitrogen than thin-skinned, though this is not invariably the case. The quantity of phosphates in barleys, though very variable, bears no relation to the percentage of nitrogenous ingredients. Marx considers that chemical analysis is the only means of judging grain if the brewer requires regular fermentation and sound yeast.

**

The *Bengalee* notices the fact that one of the leading vernacular papers of the City, the *Bangobasi*, has been threatened with prosecution for certain complaints made by it concerning the relief operations that are being conducted in Burdwan by Mr. COXHEAD, the magistrate. We suggest to this officer, who has so honourably distinguished himself from the first, by the concern he has shown for the distress of the people, that it is not wise to weigh every word that is spoken by the Press in times like these. The *Bangobasi* has taken the deepest interest in the state of the people, while the extraordinary apathy of the Government has shocked the Native mind very deeply. The *Bengalee* publishes a letter from the local Government, dated 11th instant, in which the Indian Association are told, in reply to their representations of the condition of the people in the neighbourhood of Nulhatti, "That the advisability of granting advances for agricultural purposes had already been realised by the local officers, and that estimates of the amount required in the distressed tracts are expected to reach Government shortly, and that in the meantime, the Commissioner and Collector have been asked for full particulars, as to the increase of numbers resorting to the relief centres and the probable causes of the increase."

The Government seems never to realize properly, that famine is one of those calamities, the relief of which must be prompt, to be of any avail. Enquiry ought not to be necessary at this stage of matters. The circumstances of the people have been long known to the district officers, and our contemporary points out justly, that while inquiries are being made at this hour, the season for cultivation is slipping by; and if the opportunity is now lost—if there is to be no cultivation this year, as there was none last year—the Government will incur a responsibility, the magnitude of which it is difficult to exaggerate. The Government might at once order that the *tuocavi* grant, for the excavation of tanks—which will not now be wanted—should be employed for making advances to the people for “agricultural purposes at once, and without waiting for estimates. Every penny is precious.” We may conceal it from ourselves, if we like, but it is unhappily too clear that famine is never met in the right spirit. The Civilian mind is always haunted by the fear of doing too much, and the almost uniform result is that nothing is done on a scale commensurate with the sufferings of the people. We have done all that it was in the power of a single journalist to do, to awaken a more just sense of the claims of the people upon us at these periods, and have failed.

The following is a summary of the weather for June 1885:— On the west coast the weather of the first few days of the month was marked by a few unimportant showers. On the 11th, however, there occurred a rather heavy fall of rain at Bombo, and a moderate fall over the south and west of the peninsula, and from that day onward throughout the month, there was more or less daily rain in Ceylon and on the southern coast of India. This rainfall has, however, been distinguished by two noticeable characteristics. In the first place, the fall has been accompanied by a very unsteady monsoon wind, while in the second place, and probably on account of variability in the wind direction, the extent of the fall has been greatly restricted. This unsteadiness of the monsoon wind was particularly striking on the 8th and 9th, when a wind apparently skirted the west coast, travelling in a north-westerly direction, causing a marked disturbance of the average metric distribution, and drawing the wind over a large part of western and south-western India into south-east, and in some places into east, a direction opposite to the normal. In Bombay itself, the burst of heavy rain which usually characterises the setting in of the summer monsoon, on the Konkan Coast, has not occurred throughout the month, and the winds over that region appear to have been abnormally dry; and further to the southward, i. e., on the Malabar Coast, though the winds appear to have brought up the normal amount of moisture, it seems to have been deposited only on the western face of the Ghats, and the stations in the Deccan and Hyderabad show a great deficiency of rainfall. The weather in the Berars, Khandeish, and Gujarat has been similar to that prevailing in the Konkan, the winds having been unusually dry; while in Sind and Cutch even the small average of those regions in this month has not been reached.

As regards the Bay of Bengal branch of the monsoon, the reports show that until the 10th little rain of importance was recorded. From the 10th, however, rain fell generally over Burmah, Assam and Lower Bengal; but up to the 16th was restricted to those regions. On the 16th a small depression was forming over the Sunderbuns; and as this disturbance travelled first westward and subsequently north-westward, the rains extended up the Ganges plain, and by the 24th had set in over the greater part of the North-Western Provinces. On the 26th a second depression was formed over the Sunderbuns, and this disturbance travelling westward in its turn, fairly established the rains over the North-Western Provinces and as far west as Delhi and the east of the Punjab. The heaviest falls of rain connected with these disturbances were:—

	Inches.		Inches.
Dacca, 18th	4.60	Benares, 25th	4.66
Nowgong (Assam), 18th	4.12	Naini Tal, 29th	5.80
Raipur, 20th	3.91	Aligarh, 29th	4.90
Jaunpore, 24th	6.60		

Though these depressions appear to have ushered in the rains from Lower Bengal to the Upper Provinces, it is important to note that, as was the case last year, the districts of Northern Bengal and Behar show a deficiency. It is remarkable that the disturbances noticed above, after giving plentiful rain to Lower Bengal and Assam, appear to have passed over Behar in a condition of diminished energy, but on reaching the North-Western Provinces, they seem to have again suddenly intensified and occasioned heavy precipitation. In the central parts of the country and the eastern half of the Peninsula, the returns show that Orissa and the Northern Circars have had less, and the Central Provinces and the Carnatic more, than the average amount of rain. With regard to the other meteorological elements, pressure on the whole has been above the average of the month, except in Bombay, the Berars, Hyderabad, the extreme south of the peninsula, and Orissa. In four of these five provinces precipitation has been deficient, so that the low barometer is probably to a great extent attributable to the high temperature prevailing in the absence of cloud and rain. The moisture in the atmosphere has been on the whole below the average, except in the Punjab, the Central Provinces, and Madras, the greatest and most general deficiency being reported from the Bombay Presidency.

SALT FOR CATTLE IN BURMAH.

We noticed briefly last week the enquiries instituted by the Chief Commissioner of British Burmah concerning the extent to which salt is usually given to cattle in that Province. We print this week the entire correspondence that has passed on the subject, omitting only the detailed replies of cultivators in the seven districts where enquiries were made. It appears that salt is given to cattle, and that they not only need it as a salutary diet, but take to it with avidity, thereby proving that it is an essential necessity in the internal economy of cattle. It is a practice that should, we think, be encouraged largely in all districts. From the correspondence before us, it is abundantly clear that salt forms an important element in the diet of oxen, and from the fact that it is administered when the animals are tired and worn out, after a hard day's work, shows the necessity there exists of impressing upon cultivators the wisdom of employing salt more largely than appears to be the case.

In the letter to the Government of India from the Officiating Secretary to the Chief Commissioner of British Burmah, it is stated that “The apparent discrepancy between the account given by the Deputy Commissioner of Tharrawaddy and that given by the Fottlement Officer of the same district is, perhaps, due to Mr. Hildebrand's having consulted *cart-owners* about Tharrawaddy, while Mr. Adamson took the opinion of cultivators, who employ their oxen mainly on field-work.” This appears to be erroneous; as, on turning to Mr. Hildebrand's report, we find the following passage in the opening paragraph of his letter:—“I have made personal enquiry from *cultivators* during my tours this season, and I have also received replies to enquiries made by township officers.” [The italics are ours.] The result of Mr. Hildebrand's enquiries to the questions asked, prove conclusively that salt is essentially necessary to the well-being of cattle, and we direct particular attention to the replies he received to the eight questions asked. In fact, the consensus of opinion is in favour of salt.

Mr. St. Barbe's report is interesting, and deals more in detail with the question at issue, than most of the other reports; but it seems to us scarcely necessary to use Burmese words written in the Burmese character, in an official report; as, to the general readers, in India particularly, the Burmese language is utterly unknown, and an otherwise interesting report becomes somewhat unintelligible. The Deputy Commissioner of Shwegyin (Mr. G. L. Weidemann) has also indulged in this practice.

Mr. Cabanis, the Assistant Director of Agriculture, British Burmah, makes a somewhat sweeping assertion, which is not quite reconcilable with the general tenor of the various reports on the subject. He says that his enquiries of the cultivators have met with the result that not one gave salt to their cattle, except in cases of sickness. Further on, he says: “I have noticed the cattle fighting among themselves to get to a salt-

lick," and mentions three places where salt-licks exist. He adds that "salt is given in America regularly, except in the neighbourhood of good licks, which are rare in the Eastern States. It is generally given once a week, and about two table-spoonful per head are given." With such testimony before them, our district officers should make it their business to encourage cultivators to give salt to their cattle. The question is one which ought to be taken up vigorously by the several Departments of Agriculture in India. Many of the diseases to which cattle are subject might be traced to the want of salt in their food.

It has been demonstrated, moreover, that the question of duty on salt has nothing whatever to do with the matter; and that were salt cheaper than it is, more would not be given to cattle. In Burmah, the duty on this commodity is very light; indeed, it may be said to be almost inappreciable. But this is not quite the case in India, where it has always been a vexed question. The monopoly of salt duties is entirely in the hands of Government, and it behoves the Government to make the duty on this necessary of life so light as to bring it within the reach of the humblest cultivator. The subject of salt duties is a very wide one, involving many intricate questions of policy and finance, which do not come within the scope of this paper. Our object in noticing it here has been merely to point out that in instituting these enquiries, the Government of India will bear in mind, that it is hopeless to expect cultivators to use salt largely for their cattle, so long as the duties on it put it beyond their reach.

THE DISTRESS IN BEERBHOOM.

THE following letter from the Beerbhoom district was sent to the *Statesman* a few days ago. We make no comment upon it, but ask the public what they think of the facts it discloses? We have no reason to suppose that the writer, who sends his name, wishes to mislead us, or to create a scandal against the Government, and yet here is what he says:

The much dreaded "wooding out" operation has commenced, at least at Shahapora. The officer in charge of the relief operations has, I understand, received orders to reduce the number of recipients as much as possible. This officer is, by the way, a probationary Deputy Collector on the threshold of his service, and not sufficiently hardened, I suppose, to loyally carry out his orders. It is said that while his young heart was rebelling against his work, a veteran of fifty-two battles appeared at his elbow, and at once removed all his scruples. So the cutting-down relief process is now in full swing.

Under the present arrangements, only the absolutely crippled will receive the gratuitous relief of twelve annas a month; the others being required to do more work than a robust man can do. It is worse than a denial of relief altogether. For every ten seers of *ghooting* (lime-stone) collected and carried to the relief centre, the pay is one pice or three pices. Now remember that the relief centre at Shahapora serves for 30 miles of distressed area. Imagine a half-starved woman, with one or two children to feed, and herself reduced to a skeleton, having to collect 10 seers of *ghooting*, and to carry them at sun-down a distance of say three or four miles to the relief centre to get in return one pice as food for herself, and her children! If this is not deliberate starvation of the poor, I do not know what is. Is there no power in the country to arrest and punish such cruelty?

Unless the men who are committed to the No-Famine theory, and who have misinterpreted every fact in connection with the people, are removed from the place altogether, there is no hope for the poor famine-stricken creatures.

The season for sowing and transplanting is nearly over, but the paddy fields are as bare as the floor of Belvedere. Cholera, I am glad to say, has all but disappeared from the town, so there is no danger in his Honor's paying his intended visit to this place.

I am glad to inform you that the *Dangubashi* has sent money to open a relief depot at a place called Batkar near Shahapora. This will be some set-off to the cruel neglect of our Government officials.

DISTRESS IN LOWER BENAL.

A WRITER in the *Englishman* of the 22nd ultimo, professes to believe that the accounts which have been appearing in almost every Calcutta newspaper as to the sufferings of the people in the lower districts of these provinces, owing to the failure of last year's crop, and the appeals which have been made to the local Government to take adequate measures for their relief, have their origin simply in the disappointment of

certain persons who hoped to make their relief an occasion for robbing the public treasury. The charge is prefaced as follows:

There has been a good deal of cheap sympathy wasted over these-called famine. In spite of all the shrieking of the native press, it is hardly necessary to say that, far from there being a famine, there has not even been a severe scarcity.

The columns of the very paper that prints this story, have contained urgent appeals from the district magistracy for the assistance of private charity to the people, and Mr. COXHEAD is to this hour administering funds subscribed in answer to his appeals for help. The writer proceeds to charge the native papers—which have so honorably distinguished themselves by their efforts to inform the public mind of the true state of matters amongst the people—as follows:

The real grievance of the native papers, however, is that there has been none of that lavish disbursement of Government money which gives the word 'famine' a golden sound in the ears of a large and miscellaneous class. There has been no opening for the jackals. Indeed, to many, after having had the means of suddenly enriching themselves almost brought within reach, the thought that there is to be no famine after all is positively maddening. It is a pitiable sight to see these creatures prowling around, and hungering to turn the distress of the district into a harvest of ill-gotten wealth.

With the history of our famine relief operations in the last 25 years fully before our mind, it is difficult to characterize such charges too strongly. Where and when have these practices prevailed? We have a minute memory of every famine that has occurred in India in the last 25 years, and the only circumstance we can recall throughout the period, that gives the faintest justification to such a charge, is the extravagance which marked every measure of Sir RICHARD TEMPLE's relief measures in 1873-74, when the Behar planters reaped a harvest of rich gains from the transport of grain, so wildly urged by him at all costs. We can recall no other period of famine in our time, in which the relief measures of the Government were not an absolute mockery of the people's sufferings. In 1860-61 the Government professed to brace itself up for a great effort to relieve the people in the North-West Provinces whose sufferings in that year were so terrible. The late Colonel BAIRD SMITH's report on the famine, remains the monument of our failure to this hour: a million of people having died of hunger in that calamity. The famine in Orissa, five or six years later, was so effectually met, that the civilized world was struck with horror at the narrative of a third of the population being swept away. The famine in Rajpootana followed within a year or two, when the same disgraceful and utter failure was witnessed, and another million or more of the people died. A famine simultaneously occurred in the Behar districts, and again the people perished by myriads. Four years later came the scarcity in Behar and Bengal, when for the first time in modern history, the Government met it in the right spirit; and had Lord NORTHBROOK not unfortunately conceived a strong jealousy of Sir GEORGE CAMPBELL—who was as fully alive as himself to the action that was necessary—Sir GEORGE would have carried the people through the scarcity without the loss of a life, and at an expenditure of one-fifth of Sir RICHARD TEMPLE's extravagant outlay. We owe the reaction that has since set in, to the measures taken by this gentleman in concert with Lord NORTHBROOK and Major BAIRD. The very same man, when the terrible famine of 1877 began to disclose itself in Western and Southern India, now went to the most cruel extreme in the opposite direction, and the result of his interference as delegate from the Supreme Government, was finally seen in the dreadful record that four to five millions of the people had died of hunger in Western India and Madras, and a fourth of the entire population of Mysore. Early in the next year, 1878, came the famine in the North-West Provinces, in which Sir GEORGE COUPER and Sir JOHN STRACHEY privately arranged that 'nothing' should be done, but even the land revenue exacted as in ordinary years. Many in Calcutta must remember the vehemence with which the *Englishman* and the *Pioneer* denounced the *Statesman* at that time, for insisting that the people were perishing. Then, as now, the Government was declared positively to be doing everything that the circumstances of the people required, to be met at last by a disclosure that ought to have led to the dismissal of both those great officials

from the service of the Crown for all time. They had not only done nothing, but had issued private orders that nothing was to be done. We estimated that 600,000 of the population died of hunger in that famine, and our columns teemed with the most harrowing description of the sufferings of the people. Sir JAMES CAIRD publicly raised our estimate of 600,000 to 1,250,000 in a letter to the *Times* in 1880. And with these dreadful facts in our remembrance, this writer in the *Englishman* dares tell the public that the cause of the present outcry is that the native papers are in league with a gang of plunderers, who are disappointed that the treasury doors have not been flung open, as they usually are at these periods. We have never once known those doors opened as they should be, but in the Behar mania, when we opposed Lord Northbrook's extravagance. The native papers of Calcutta deserve nothing but the highest praise for their exertions in the present sufferings of the people. The action of the Government has been shamefully inadequate to their needs. When this writer says "that some of the statements regarding the actual amount of relief given in certain cases, are monstrously false, and are merely intended to facilitate the manufacture of a famine," we ask what statement could be worse than that of the Collector of Burdwan himself the other day, that he was giving the destitute adult 2 pice a day, and the child but 1 pice, and that to save the pinch of dal and the cost of the firewood in the cooking, he was giving the rice raw. It was not the native papers that made the statement, but the relief officer himself; and as we saw, it was approved by the Lieutenant-Governor, without a thought of what it meant. If we err at all at these times, we should err on the side of liberality, whereas the uniform story is of measures scandalously inadequate to the circumstances of the people, with the uniform result of their dying in such numbers that every effort is made to conceal them from the public. Sir RIVER S THOMPSON has revived traditions of the service, in dealing with this calamity, that we hoped had finally disappeared from amongst us.

Miscellaneous Items.

THE Gos treasury, it is expected, is to receive Rs. 1,90,000, in the shape of salt-pans' indemnity, from the British Government. Of this sum, Rs. 1,50,000 are to be paid to landholders on the Marmagba Railway Line, and Rs. 40,000 to the owners of salt-pans.

On the 16th July twelve shocks of earthquake were felt at Srirangar, one being very violent. The floods have subsided lately, and the damage done is confined to a small part of one of the four districts of Cashmere. In the rest of the valley the prospects of the crops continue good.

A CORRESPONDENT from Simla says that a rumour is current there, to the effect that his Excellency the Viceroy and Governor-General of India has asked for detailed translations of the views expressed by the Native Press in the Bengal Presidency, on the present distress in some parts of Bengal.

THE gold medals, distributed by the Governor of Pondicherry to the persons who had particularly distinguished themselves during the inundations of November and December 1881, are handsome and massive, containing about Rs. 50 value of gold in each. The name of the owner and date is engraved on the medal, with the words, "Awarded for courage and devotion."

THE High Court lately addressed Government, drawing attention to the desirability of passing early a legislative enactment to exclude suits for arrears of rent of land from the jurisdiction of village Moonsiffs. Government have coincided with the High Court in the desirability of such a measure being carried out, and the matter is now receiving attention in the Legislative Department.

H. H. THE NIZAM is anxious to keep up horse-breeding in his territory, and has selected Aurangabad for the purpose. His stud at that place consists of seven stallions and mares. Another batch of eighteen are to follow, making a total of twenty-five. Captain Abdulla is to be in charge, and will visit Aurangabad occasionally. The farm is being built outside the city, where fodder and water are plentiful.

THE Press Commissioner has issued the following:—For the benefit of goods manufactured in Persia, H. M. the Shah in 1882 issued a decree, interdicting the importation into and the sale of aniline dyes within his territories. Information has now been received by the Government of India, that H. M. has recently placed a similar restriction on the importation into Persia of thread colored with such dyes.

At the end of the last official year, there were seventy-two Jute ware-houses in the town of Calcutta. The license fees realized during the year under notice from them amounted to Rs. 23,275, or Rs. 121-10 8 more than last year. There were two cases of fire—one at No. 1, Ahireetolah-street, and the other at No. 43, Nintollah Ghat-street. The loss sustained by the owner in the former case amounted to Rs. 1,000, and in the latter to about Rs. 14,000.

We are much gratified to hear that the shipping trade between Singapore and Bangkok has increased greatly of late, and that to keep pace with this increase, Messrs. W. Mansfield & Co., Agents of the Ocean Steam Ship Company, are shortly expecting a new steamer called the *Hecate*, to establish a weekly service, in connection with the *Hecuba*, which has hitherto performed the run fortnightly. The *Hecate* is in all respects a sister ship to her future consort.

We have been favoured with a copy of Vol. II, Part IV, of *Meteorological Memoirs*. They are interesting in various ways, one object in view being to indicate that there are probably definite relations between the number, character, and paths of the south-west monsoon storms of the Bay of Bengal, and the larger abnormal meteorological conditions of the year. The subject of storms should be more closely studied by the general public than it is. These memoirs contain much useful information on this subject.

THE total number of deaths registered in the Suburbs of Calcutta, during the week ending 4th July, was 149, against 136 and 146 in the two preceding weeks. Under the head of cholera, there were 22 deaths, against 33 and 17 in the two preceding weeks. During the week under notice there were 3 deaths from small-pox, 43 from fever, 19 from bowel complaints, 2 from injuries, and 60 from other causes. The general mortality was at the rate of 31.8 per 1000 per annum, against 28.1 and 30.2 in the two preceding weeks; while it was 23.8 in Calcutta during the same period.

THE Government Director of Bangalore Woollen Mills, Mr. Ricketts, has issued instructions to the Secretary to take out proceedings at once against defaulting shareholders. There are in all something like twenty shareholders in the concern, who own from one to twenty shares, who have not paid up, and the capital represented in the aggregate by these holdings amounts to about Rs. 12,000. This is certainly a very large outstanding, and the money if collected may help to give a great impetus to the enterprise which it very much stands in need of just now.

ON Tuesday last week the Irrawaddy Flotilla steamer *Irrawaddy* arrived from Mandalay, and amongst her cargo were 105 bags of what purported to be tamarinds, consigned to a local Chinese firm. In examining these bags, Mr. Lalimour, Customs Preventive Officer, had his suspicions roused as some hard substance within resisted the probe. He thereupon opened one of the bags, and found in the midst of some fruit a quantity of lead. The bags were strictly watched, and when a Chinaman came to take delivery he was taken into custody, and admitted that some fifty bags contained lead, and that this subterfuge was resorted to to evade the duty leviable at Mandalay by the Upper Burmah authorities.

THE total number of deaths registered at Howrah during the week ending 4th July was 44, against 46 and 40 in the two preceding weeks. Under the head of cholera there were 2 deaths, against 6 and 2 in the two preceding weeks. There were 23 deaths from fever, 5 from bowel complaints, and 14 from other causes. There were no deaths from small-pox and injuries. The general mortality during the week under notice was at the rate of 21.7 for 1000 per annum, against 22.6 and 19.7 in the two preceding weeks, while it was 30.3 in the Suburbs and 23.3 in Calcutta during the same period. Howrah would therefore seem to have been healthier than Calcutta, not to say the Suburbs, during the week under notice.

THE total number of deaths registered in Calcutta during the week was 209, against 201 and 195 in the two preceding weeks, and 52 in excess of the corresponding week last year. There were 29 deaths from cholera, against 22 and 16 in the two preceding weeks, the quinquennial mean being 9. The disease for the past 3 weeks has shown a tendency to increase, and it will probably continue to do so to a slight extent until the rainfall becomes heavier. There was only one death from small-pox during the week, and none in the previous week, so that the prospects with regard to this disease continue to be favourable. Fever and bowel complaints were slightly in excess of the average during the week. The general mortality was at the rate of 25.1 per 1000 per annum.

It will no doubt be a matter of rejoicing for the Opium Society, to learn from the report on the foreign trade of Oudeh, for the year 1884, that the net quantity of foreign opium, taking all kinds together, which has been imported through the foreign Customs Department, has varied but little during the last three years, and at any rate has not shown an increase. There was a slight rise in the quantity of Malwa opium imported, but the import of Patna opium has fallen off from 16,593 piculs to 13,890. Benares opium has also been in less demand, as the quantity imported has fallen from 18,000 piculs (one of the largest importations ever known) to 12,400 piculs; whilst Persian and Turkey opium have fallen from 6,600 piculs, in 1881, to 4,400 piculs in the year 1884.

THE Poona Sarvajanik Sabha presented an address of welcome to Lord Reay at the Council Hall, Poona. Among the questions to which the members invite his Excellency's attention is that of forest conservancy. The Sabha remark that this affects not only Thana, but more or less all parts of the presidency. The people fully appreciate the natural anxiety of Government to spare no effort to restore the old state of things. But they feel that the details of forest administration require to be very carefully watched, lest the interests of the present generation may be unduly sacrificed to those of posterity, as they fear they are at present. Perhaps the idea of making this department a source of revenue lies also at the root of many of the existing abuses, and consequently the vested interests of many helpless classes are possibly endangered by a too stringent method of working. The best way in which the public and private interests might be reconciled would be by the appointment of a Commission of European and native experts as had been resolved upon.

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The Ordinary General Meeting was held on Wednesday, the 24th June 1885.

PRESENT:

D. CRUICKSHANK, Esq., Vice-President, in the Chair.

Mr. John Martin. Baboo Protapa Chundra Ghose.
 „ P. Playfair. Mr. W. H. Miles.
 Dr. S. Lynch. „ R. Blochynden, Jr., Deputy Secretary.

COMMUNICATIONS.

From Mr. D. Allen, C.S., Bankipore, enquiring if Eucalypti are likely to grow well in the Barrh sub-division of Patna District, and requesting to be put in the way of procuring some seed, as well as instructions for the best mode of cultivating them. Small quantities of the seed of three varieties—*Eucalyptus rostrata*, *E. resinifera*, and *E. globulus*—were sent to Mr. Allen, with instructions for sowing.

From Mr. James E. Bridges, C.S., Officiating Secretary to the Chief Commissioner, British Burmah, in reply to an enquiry, stating that the Chief Commissioner has no objection to the reproduction in the Society's Journal of Mr. Wood-Mason's Report on an insect which attacks the paddy crops, if that gentleman consents to it. He adds that he regrets that no accurate information can be given regarding the extent of the damage done by this insect. As Mr. Wood-Mason's consent was obtained before the Chief Commissioner was addressed on the subject, his interesting paper will appear in the next number of the *Journal*.

From Captain A. Barrow, Kooloo, Kangra, who writes:—"I send you by parcel post a few specimens of a large fern called in Kooloo 'Lengri'; when eaten young it is a most delicious vegetable. Can you very kindly tell me its name, and whether it grows in England? I hunted for it last year in Hampshire, but could not find it. How could it be introduced into England?"

"All the peaches in Kooloo have been attacked by some disease, which kills the trees. I send you some specimens along with the fern. Can you tell me what the disease is, and how it can be cured?"

The parcel arrived in a very damaged condition; indeed, with the contents quite unrecognisable; fortunately, the native name given for the fern is sufficient for its identification as the *Pteris Aquilina*, the bracken, common to so many parts of the world, including England.

Captain Barrow also mentions that all last year's potatoes have become diseased, both in Kooloo and in Kangra Valley, and none are procurable. It is to be hoped that care will be taken to reject any unspeaked seed when the planting season arrives, for it may give the cultivators much trouble.

ENGLISH POTATOE SEED.

Another report has been received on this seed, which was presented to the Society last year by Mr. W. Stalkart. From the quantity sent to him, Mr. F. W. Blechynden, of Champarnu, sent the greater part to Mr. Girdlestone for trial in the very favourable climate of Nepal. The result is very disappointing and compares very unfavourably with those recorded by Mr. Anderson, C.S., of Banooora, or by Mr. Blechynden, in the *Proceedings* for March last. Two of the three varieties yielded Mr. Anderson six-fold and five-fold respectively, the third was a failure. Mr. Blechynden got 5½, 6½, and fourfold from the three varieties he planted. The following is Mr. Girdlestone's report:—

Ashleaf	Planted 12 lbs.	Outturn 52 lbs.
Victoria	14 "	30 "
Late Rose	12 "	50 "

"The potatoes were sown in an ordinary field, on ridges well separated by furrows, in a light soil moderately manured with compost of leaf mould and stable refuse; they were kept well weeded, and had constant waterings during the late dry spring. They were not attacked by insects. I cooked some of each kind, but did not find them better than varieties already in the valley."

APHIDS ON TEA LEAVES.

From Messrs. George Henderson & Co., forwarding an extract of a letter from Mr. Troup, of the Mullakattayoor Tea Estate, Kunnion, with specimens of the affected leaves alluded to, asking for a report. As other planters may have been troubled with similar experience, Mr. Troup's description, with the report kindly furnished by Mr. Wood-Mason, are both given in full:—

Extract from a letter, dated the 7th June 1885, from NORMAN F. T. TROUP, Esq., of the Mullakattayoor Tea Estate, Rackington, Baijath, Kunnion.

"By this day's post I am sending you a few sprigs of a Tea bush that presents a most curious appearance, and should feel very much obliged if you would kindly get some of your friends learned in such matters to explain what is amiss with them."

"The leaves of the bushes that are thus affected present a varnished appearance, and are coated with some sticky substance like honey which is also as sweet as honey, and the young shoots are covered with a small winged brown fly like the green fly that attacks some kinds of flowers in green-houses. There are also some small six-legged insects like bugs on these bushes, of a slateish black colour dotted with white. I at first thought that these insects were accountable for both the brown fly and sticky substance on the leaves, but so far as observation has enabled me to ascertain, they only prey on these flies. I observed the same sticky substance on the bushes during the winter, but then concluded it to be an abnormal supply of honey in the flowers, as at that time it was dropping out of them, but now there are no flowers for it to come from."

"This fly, other insects, and the stickiness do not seem to affect the health of the bushes, as those they are on look as vigorous, and are flushing as freely as those free from them."

"Up to date we, in this district, have been entirely free from all tea pests, and hence my curiosity and ignorance regarding this one, if it is a 'pest.'"

Mr. Wood-Mason's report:—"The sweet and sticky substance on these leaves is no doubt 'honey-dew,' mixed with exuded sap. Many leaf-lice (*Aphide*) are provided on the dorsal surface of the ante-penultimate abdominal segment, with a pair of tubular prominences, the so-called 'honey-tubes,' each of which bears at its extremity a minute pore. From these pores, there continually exudes a sweet fluid, secreted by special glands, and eagerly sought after by ants, the so-called 'honey-dew,' which is frequently deposited upon the leaves frequented by the lice, there becoming mixed with the sap that exudes from the punctures made by these insects with the four stiletts of their sucking mouth in feeding. Hundreds of the lice [the 'brown bugs' of your correspondent are females and young, and the 'brown flies' are males] are glued to the different parts of the tea-plant, as also are numbers of the fluffy white oast skins of larvae which are popularly termed 'mildew,' though they have nothing whatever to do therewith. The matter is of no practical importance whatever."

FUMIGATION FOR INSECT PESTS.

Mr. Claude J. Dumaime lately suggested that fumigating with Mohwa oil-cake, if done immediately on the first appearance of insect pests, while still affecting small areas, might be usefully tried by tea planters and others. He was asked to communicate his own experience, and writes as follows:—"*Commuri Oil cake* is made from the seed of the Mohwa (*Bassia latifolia*) from which the oil has been expressed. I was given to understand that the smoke from it, when burned in a house, was sure death to all kinds of insects. This gave me the idea of trying it in the open air. Some of my paddy, rahar, and moong dal, having been attacked by blights, I gave it a fair trial, which proved a success. I got a number of ordinary *hanties*, and filled them three-quarters full with dry cow-dung cake, and after firing filled up with *commuri* oil-cake. The *hanties* were then distributed on the windward side of the affected fields. The wind that day was nominal, and the smoke was very great, and I can certify that none of the blights outlived the operation. The plants were in no way affected. I fancy 20 seers might be enough for a square Bengal beegah."

"The cost of the oil cake is Rs. 4-8 a maund, delivered at Howrah Station, exclusive of bags, and it is only procurable at a certain time of the year. I shall be glad to procure some for any person wishing to give it a trial."

EARLY AMER SORGHUM.

Mr. A. Whyte, junior, of Raneebunge, writes in reference to this Sorghum:—

"In the early part of last year I wrote informing you that I contemplated making an experimental silt as well as growing the early Sorghum up here, and promised to give you the results of my experiments, which I have now much pleasure in doing."

"I will be very much obliged if you would kindly aid me with any advice you may be in a position to give, in reference to the cultivation of the Sorghum, as I seem to have failed somewhat in my experiment with it."

"I should mention that although I received the Sorghum seed from you on the 25th of May 1884, I was unable to sow it until the 12th of July, owing to some difficulty in securing the lease of the land, and it was too late then to do much in the way of preparing the land by ploughing and manuring, as the rains having set in rendered the ground unfit to work; so that the failure I have above alluded to may be in some way accounted for by this fact."

"The plants when they grow up proved generally very thin, and some of the thicker ones were of a reddish spongy appearance inside. The canes were from $\frac{1}{2}$ to 1" in diameter, and from 8 to 10 feet in height, and were cut on the 29th of October, as soon as the seed had ripened on them. You sent me 2 lbs. of this (Early Amber Sorghum) seed, and the juice extracted from the whole crop by the common native mills weighed three maunds, ten seers; but though I employed the men most skilled in converting the sugar-cane juice into jaggery, their efforts to do so with the juice of the Sorghum were a failure. I intend to try the experiment again this year, and have had the land well ploughed and manured for the purpose; and I think by sowing it a month earlier and planting the seed about two feet apart (I may here mention that last year it was sown broadcast,) it may be attended with better results. I shall, however, be glad to receive any directions from you as to the method of sowing, and converting the juice into jaggery, as I am anxious to make the experiment a success, as the natives here seem quite astonished that sugar-producing Sorghum can be grown from seed, and are therefore interested in the results.

"Notwithstanding my want of success I had applications from cultivators who were desirous of trying the Sorghum themselves, and wished to purchase seed from me.

"Although the syrup could not be converted into jaggery successfully, yet to test its value, I had what was made sold, and it found a ready market though at a low price, for conversion into sweetmeats, &c."

Mr. Whyte has been informed that, according to the information at our disposal, the point requiring greatest attention in making Sugar from Sorghum, is the time at which the cane should be cut. The American Agricultural Department to whom the recognition of the capabilities of the plant is due, and who have made a vast number of experiments with it, have divided the growth of the plant into stages for convenience of reference in their reports; these stages are numbered and lettered as follows:—

Stage.

Development of Plant.

- E. About one week before opening of panicle.
- F. Immediately before opening of panicle.
 1. Panicle just appearing.
 2. Panicle two-thirds out.
 3. Panicle entirely out: no stem above upper leaf.
 4. Panicle beginning to bloom on top.
 5. Flowers all out. Stamens beginning to drop.
 6. Seed well set.
 7. Seed entering the milk state.
 8. Seed becoming doughy.
 9. Seed doughy, becoming dry.
 10. Seed almost dry, easily crushed.
 11. Seed dry, easily split.
 12. Seed split with difficulty.
 13. Seed split with more difficulty.
 14. Seed split with still more difficulty.
 15. Seed harder.
 16. Seed still harder.
 17. Seed still harder.
 18. Seed still harder.

"Determination of the stages, after No. 14, was more difficult than that of the preceding ones, and depended on the increasing hardness of the seed."—Agricultural Bureau's Report, Washington, for year 1882-83.

The reports further on show in a tabulated form, which need not be reproduced, that the percentage of juice extracted from the stripped stalks gradually increases up to the eleventh stage, then slowly decreases to the end of the season. The specific gravity of the juice, the percentage of sucrose, the percentage of solids not sugar, and the exponent, regularly increase (with but one or two exceptions) until the close of the season; and the percentage of glucose in the juice as steadily decreases from the first.

In another place it is stated that 'in their early stages of development, up to and including the sixth stage, the available sugar is given in a minus quantity, i. e., the amount of sucrose in the juice is less than the sum of the glucose and the other solids; this means in practice that there is no available sugar, and consequently it is argued that immature cane should not be mixed with ripe cane, as it is not only worthless in itself but causes the loss of sugar otherwise available; a number of figures are brought forward to prove this statement, and it is mentioned that the sugar planters in Cuba and Louisiana recognise the fact, and cut off and leave in the field the immature tops of their *Sugarcane*, having learned from experience that sending them to the mill results in actual loss in sugar produced. In mature *Sorghum*, however, there is no practical difference between the quality of juice contained in the top, or in the butt of the plant; suckers should be discouraged and not be cut with the crop.

In the experiments conducted at the Government Farm, Cawnpore, during 1883, noted in this Society's *Journal*, Part II, Vol III, some 18 or 20 maunds of *gour* were made, without the addition of lime, yet the juice was manipulated with the same ease as that of the sugarcane. Still the report kindly given by Mr. Turner on the sample received from there, was unfavorable, namely, that it was valueless to the refiner.

It seems probable that the Indian practice of boiling the juice in pans directly over a blazing fire is fatal to the proper crystallization of the sugar.

SILOS.

Mr. Whyte, in the same communication above referred to, reports on his silo experiment:—

"My silo experiment, I am glad to say, proved rather more successful. It was a brick-built one of the following dimensions, 10x8x8 feet. It was loaded on the 14th of October 1884, and

as the seed of the *Reana Luxurians* you so kindly sent me for the purpose yielded only enough to fill three feet high of my silo, and I was unfortunately away from the station at the time, it never occurred to the natives whom I left in charge to fill it up with other grasses, since I omitted to mention to them that this may be done, believing the crop of *Reana Luxurians* would be ample; so it was closed, with only the above quantity. On the 15th of April this year upon the silo being reopened, the fodder was not only found to be in a perfect state of preservation, but the cattle to which it was given ate it so eagerly as to convince the natives to whom they belonged of their appreciation of it. At the opening of the silo were present besides Mr. T. Inglis, Sub-Divisional Officer of Raneengunge, and Mr. G. H. Walsh, Officiating Magistrate, several Native zemindars and ryots, who had been invited by Mr. Inglis to be present."

"This year I intend to make a silo by simply digging a pit in the ground, and loading this as well as the brick-built one of last year with country grasses, as there seemed to exist in the minds of the natives some doubts as to the country grasses standing the test, attributing the success above-mentioned to the grass being the produce of foreign seed."

In a subsequent communication, Mr. Whyte mentioned that he had, in conjunction with Mr. Inglis, the Sub-Divisional Officer, caused the day on which the silo was to be opened to be widely known, and great interest was shown by natives of all classes in the neighbourhood, who assembled in crowds on the day appointed, and who thoroughly admitted the success which had been achieved in preserving the fodder. Some of them, however, attributed the success to the fact of the grass ensilaged being peculiarly suited to the process, and as many took intelligent interest in the proceedings, and obtained all particulars regarding ensilage from Mr. Whyte, a quantity of *Reana Luxurians* seed is placed at his disposal to distribute among those who will try it practically themselves. Parts of districts of Beerbhoom and Baccora are perhaps more in want of a system of storing fodder than any other places in Bengal, for, from the middle of March till the rains set in, the grass in the laterite soil gets quite burnt and withered, and can barely sustain life in the cattle, who are thus reduced to skin and bone just at the time when the heavy work of ploughing the paddy land commences. The laterite soil is well adapted for pit silos, and Mr. Whyte may be the means of introducing an urgently needed system into these districts.

RICHARD BLECHYNDEN, JUNIOR,

Deputy Secretary.

SALT FOR CATTLE IN BURMA.

From J. E. BRIDGES, Esq., C.S., Officiating Secretary to the Chief Commissioner, to the Secretary to the Government of India, Revenue and Agricultural Department, Simla, No. 1101-13C,—Dated Rangoon, the 6th July 1885.

SIR,—I am directed to submit copies of the papers concerning the extent to which salt is usually given to cattle in Burma. It has on occasions been supposed that the Indian salt-duty prevents cultivators giving to their oxen a due allowance of salt. The salt-duty in Burma is one-tenth of the present duty in other provinces of the Indian Empire, and it seemed interesting to enquire whether Burmese owners usually give salt to their cattle.

2. The net result of the present reports is that Burmese do not give salt regularly or usually to their cattle. They often, however, give a little salt to buffaloes or oxen that are working particularly hard or plying in the sun. In tracts where cattle are fed on straw, salt is more frequently given. In the delta, and in places where the soil is impregnated with salt, cattle often resort to salt-licks. It would seem that salt is given more usually to cattle plying with carts than to plough-cattle employed in the fields. The apparent discrepancy between the account given by the Deputy Commissioner of Tharrawaddy, and that given by the Settlement Officer of the same district is, perhaps, due to Mr. Hildebrand's having consulted cart-owners, who employ their oxen mainly on field-work.

3. The papers may have some general interest, in as far as they throw light on the question whether Indian cultivators would give salt more freely to their cattle if the salt-duty were lighter than it is in most Indian provinces.

From R. F. FROST, Esq., Veterinary Instructor, British Burma, to the Commissioner of the Pegu Division,—No. 3290, dated the 11th June, 1885.

In compliance with the orders of the Chief Commissioner, Land Revenue and Agricultural Department, No. 2299-190, dated Rangoon, the 18th October 1884, I have the honor to forward replies on the question of the consumption of salt by cattle in British Burma from the following officers, namely,—the Deputy Commissioners of Tharrawaddy, Kyaukpaya, and Shwegyin, and the Settlement Officers, Pegu, Tharrawaddy, Henzada, and Akyah,

together with a note on the subject by the Assistant Director of Agriculture.

2. I may here record the result of inquiries made by myself during the last seven months in the districts of Hanthawaddy, Pegu, Tharrawaddy, Prome, Thayetmyo, Henza-la, Thongwa, Shwegyin, and Akyab.

3. I find that salt is very little used for cattle in most of these districts. In some it is given sparingly; in others not at all.

Very little, if any, is given to buffaloes. Its use seems to be confined to working oxen.

When cattle are worked in the sun, or when they are about to start on a long journey, some owners are in the habit of placing a little salt on the tongue and rubbing a little on the nose rope and muzzle; but even this is by no means a general custom.

4. In exceptional cases, where cattle are hand-fed by careful owners, a little salt is sprinkled over a mixture of chopped straw and linseed cake.

5. Occasionally a small quantity of salt is sprinkled on a sieve and placed within reach of the cattle to lick, and the posts to which oxen are tied have salt applied to them so that the cattle may lick them. The owner's object in giving salt as described above is to make his cattle fond of their homes.

6. Salt is sometimes given in conjunction with other remedies for medical purpose, but not to any great extent.

7. I have taken particular care to ascertain whether the cost of salt has anything to do in regulating the quantity given to each animal, and in no single instance have I been told that if the article could be obtained at a cheaper rate, a larger quantity would be administered to animals.

The people do not attribute any special virtue to salt in so far as it affects the general health of cattle. Indeed although cattle-owners are in the habit of putting a little salt on the tongue of working oxen, not two men out of every hundred of those consulted by me could explain the action of salt given in this way. The reply which I have invariably received when endeavouring to ascertain why owners gave salt when animals were exposed to the sun, was "that it was the custom to give it."

So far as I have been able to ascertain, Burman cattle-owners do not give salt largely or generally to their cattle.

8. With regard to the concluding paragraph of the Chief Commissioner's letter, in which I am desired to compare the facts brought to light by these inquiries with known facts as to salt used for cattle in Europe, I may state at once that if salt is used by Burmese cultivators as freely as is represented by the Deputy Commissioners of Tharrawaddy and Bassein, the cattle receive a much larger quantity of salt than is administered to cattle in England. I can write from practical experience of the conditions under which cattle are kept in the south of Ireland, and there it is by no means the custom to give salt to cattle. Indeed salt is seldom or never given. Neither is it the custom in England, except where high-class breeding is practised and animals are stall-fed.

9. There is no doubt that a more free use of salt for cattle would be highly beneficial, and that it would tend to a certain extent in rendering animals less susceptible to attacks of disease. But so far as this province is concerned, I do not think the price of the article influences the ordinary cattle owner as to the quantity of salt which he gives his cattle.

10. It may be foreign to the question under notice to add that the great need of the Burman cattle owners is not cheap salt, but an abundant water-supply during certain months of the year. But it is a question about which there cannot be a difference of opinion that in most parts of the province the quantity and quality of the drinking water for cattle during certain months of the year is decidedly bad, and I have no hesitation in attributing many outbreaks of disease to this cause alone. As this is not the place to enter into particulars on the question of water for cattle, I shall not add anything further on the matter.

From T. C. MITCHELL, Esq., Settlement Officer, Akyab, to the Veterinary Instructor, British Burma,—No. 5542, dated the 24th April 1885.

In accordance with instructions received from the Junior Secretary to the Chief Commissioner, British Burma, I have the honour to inform you that I cannot find that salt is used as food for cattle in any part of this district.

From Deputy Commissioner, Kyaukpadaung, to the Veterinary Instructor, British Burma,—No. 3049-224, dated the 30th March 1885.

With reference to Land Revenue and Agricultural Department No. 2297-190, regarding the use of salt for cattle, I have the

honour to state that all the officers of this district concur in the opinion that salt is never given to cattle except in cases of illness. The dearthness of the article is not the reason why it is not given. The cultivators do not know of, and in fact do not believe in, its utility as an ordinary article of food for cattle.

From Captain B. A. N. PARROT, Settlement Officer, Pegu, to the Veterinary Instructor, British Burma,—No. 155-1, dated the 24th October 1884.

With reference to letter No. 2297-190, dated the 18th October, 1884, from the Junior Secretary to the Chief Commissioner, directing a report to be submitted to you by April next on the subject of the use of salt for cattle by the people, I have the honour to report—

- (i) that the letter has been received too late to enable me to make especial enquiries as our work closes in a few days;
- (ii) salt is very rarely given by the Burmese to their cattle; the only occasion in which it is given is in sickness medicinally;
- (iii) some natives at Htaukyan, in the settlement tract, assert they give about three viss per head annually;
- (iv) in a great part of the Hanthawaddy and Pegu districts a quantity of salt earth exists, and salt is found all along the tidal creeks; the cattle to some extent therefore are enabled to get grass containing saline matters, and are able to lick up the salt earth, so perhaps do not feel the want of it so much;
- (v) I have frequently called the attention of the Burman to the benefits derived from giving salt, but without effect.

From A. H. HILDEBRAND, Esq., Deputy Commissioner, Tharrawaddy, to the Veterinary Instructor, British Burma,—No. 50-1, dated the 16th April 1885.

With reference to Land Revenue and Agricultural Department No. 2297-190, dated the 18th October 1884, I have the honour to report that I have made personal enquiry from cultivators during my tours this season, and I have also received replies to enquiries made by township officers. The result of my own and their enquiries to the questions asked is as follows:—

- (1) Salt is always given to cattle when fatigued from work in the sun and at other times when they appear to require it.
- (2) The hot months of the year are the season when salt is specially given, as it is believed to counteract the bad effects of working in the sun.
- (3) Salt is given to working cattle daily during the hot months. It is given from two to four times a month; at other times, as they may appear to require it.
- (4) From two to three viss of salt is thus given on an average to each head of working cattle during the year.
- (5) This is believed to be enough, and, if salt were cheaper, no more would be given.
- (6) The cattle appear to feel and suffer from the effects of the sun if it is not given to them, but they can live and work without it.
- (7) Buffaloes get more salt than bullocks, i.e., more at a time, a buffalo from five to six ticksels.
- (8) The salt is sometimes given with rice-bran, sometimes with straw, and sometimes in a mixture of bran, oil-cake, and water. It is also sometimes given in its raw state for them to lick.

From H. ADAMSON, Esq., Settlement Officer, Tharrawaddy and Prome, to the Secretary to the Chief Commissioner, British Burma, Land Revenue and Agricultural Department,—No. 22, dated the 21st April 1885.

As directed in your No. 2297-190, dated the 18th October, I have the honour to report through Mr. Frost on the use of salt by cultivators for their cattle.

Cultivators do not give salt to their cattle habitually, and they do not mix it with their food. Occasionally, after a hard morning's work, the cultivator pushes a handful of salt into his bullock or buffalo's mouth. This is the only way in which I have seen salt given to cattle.

From H. L. ST. BARBE, Esq., Deputy Commissioner, Bassein, to the Secretary to the Chief Commissioner, British Burma, Land Revenue and Agricultural Department (through the Veterinary Instructor, British Burma),—No. 108-2, dated the 23rd December 1884.

I HAVE the honour to acknowledge your Land Revenue and Agricultural Department No. 2297-190, dated the 18th October 1884. Careful enquiries have been made in this district with the following result:—

- (1) Salt is generally, but by no means universally, administered to cattle.
- (2) It is administered not as an article of diet, or at any special seasons, but for the most part in cases of exhaustion after severe work; less often in cases of chronic emaciation, or when the animal is afflicted with a cold, or with disease of the pupil of the eye. It is regarded thus as a medicine and not as an indispensable condiment, and its use depends, not on the cheapness of supply, but on the general enlightenment on the subject.
- (3) In some circles salt is never given at all; in other circles it is given only to bullocks. In the northern circles, where cattle are generally better tended, it may be calculated that about a viss of salt is consumed by every animal each year, chiefly at the

time of ploughing. In the rest of the district the average varies from that amount to nothing at all. Most cultivators who give salt to bullocks and buffaloes alike make no difference in the doses administered to each.

(4) Salt is by no means regarded as a specific even in the limited cases where it is administered. If salt is not available, or if its action fails, there are other *nontra* equally efficacious.

(5) It is generally mixed with the shoots of the [Burmese word] commonly called *shukmanaw*, which are chopped up fine; more rarely with the root of the [Burmese word] or with pounded fruit of the shayya or melkhalin. It may be given also in rice-water (warmed), and occasionally even mixed with a little paddy-chaff.

Under the present careless system of cattle-tending and scanty veterinary knowledge, the use of salt as a regular article of diet is not likely to become prevalent, or in way affected by the cheapness of supply.

From W. T. HALL, Esq., ^{successor} ^{to} ^{the} ^{post} ^{of} ^{trying} ^{to} ^{the} ^{29th} ^{March} ¹⁸⁸⁵.
Veterinary Inspector, British Burmah, to the Secretary to the Chief Commissioner, British Burma, Land Revenue and Agricultural Department, No. 526, dated the 27th April 1885.

As directed by the Secretary to the Chief Commissioner in his letter No. 2297-190, dated the 18th October 1884, I have the honour to submit through you the result of the enquiries made as to whether Burmans give their cattle salt generally.

2. The questions laid down have been put to cultivators and also to a few cartmen, and their replies are attached.

3. It would appear that cultivators do not, as a rule, give salt largely or generally to their cattle.

Salt is given, however, to bullocks when carting in the dry weather. They are said by some to require it when working in a hot sun, and it is sometimes given during the rains to both buffaloes and bullocks. Then it is rather given to make the fodder (cut grass or straw) palatable.

Salt is nowhere given regularly every day or at certain intervals.

The salt is taken out of what is kept for household use, and so the cultivator cannot well estimate the amount he gives to the cattle.

It does not appear that more salt would be given if it were cheaper.

No cultivators state that their cattle suffer for want of salt.

Bullocks probably get more salt than buffaloes, as they get it in the dry weather, though buffaloes get more at a time when they are given any at all.

The replies of cultivators attached show how salt is given, i.e., with water thrown on straw or cut grass, or sometimes plain by itself.

From G. L. GRIDEMANN, Esq., Deputy Commissioner, Shwegyin, to the Secretary to the Chief Commissioner, British Burma, Land Revenue and Agricultural Department, No. 526, dated the 27th April 1885.

I have the honour, in reply to your letter No. 2297-190, dated the 18th October 1884, to submit the following report on the subject of the consumption of salt by cattle in this country. My enquiries have been confined to the upper portion of the district. Mr. Shaw has supplied me with the results of the enquiry made by him in his sub-division, and I subjoin the body of his report on the subject.

2.—The following facts have been elicited by myself:—

Only those persons give salt to their cattle who are careful of them.

Salt is chiefly given in the months of Tabung and Tagu (March and April) in order to counteract the effects of heat. It is sometimes mixed with water and rubbed on the spine during a hot journey as a specific, or a dose is administered after animals have undergone special exertion, or have lost condition, e.g., after the ploughing season. In these cases one *tola* is given daily from nine or ten days.

Some cattle-owners administer salt regularly three or four times a month, or even once in every four or five days, in doses varying from one to five *tolas*.

It is very difficult to state the amount given annually to each animal. In one place I was assured that some people gave their buffaloes a handful of salt daily, but it was admitted that these were in the minority.

The price appears to be no object. Too much salt is said to have a bad effect as it acts as a purgative.

There was a general opinion in favour of salt, as it was believed to keep animals in good condition. If cattle suffer from want of salt, the fault probably lies in the ignorance or indifference of the owners. Possibly if salt was more in demand for feeding cattle the price might rise, but I could not ascertain that the present price acted in any way as a deterrent. It is said to cost from Rs. 3 to Rs. 4 per annum to keep a buffalo regularly fed with salt.

There would seem to be no distinction between bullocks and buffaloes in the matter of salt-feeding, though in one respect the replies were somewhat contradictory. In one place salt was given to buffaloes all the year round because they were fond of it, while it was said that some bullocks are more greedily than others. In another place it was said that some buffaloes would not touch salt, but that all bullocks would eat it.

Salt when given to buffaloes is given unmixed. In the case of bullocks it is mixed with paddy-husk; it is also sprinkled over the straw fodder with which they are fed, when the latter has become old and unpalatable, in order to give it a relish. It is also given as medicine when the stomach is distended, no doubt as a purgative.

It will be observed that in the Sittang sub-division there are villages in which it is not the custom to give salt at all. As the ground there is more or less impregnated with salt, the administrator by hand would probably do more harm than good. There are however villages in the northern parts of the district where salt licks do not exist, but where it is said not to be the custom to give salt to the cattle, though cattle-owners could well afford it. Something would seem to depend on the quantity and quality of the pasturage in such cases.

From G. W. SHAW, Esq., Assistant Commissioner, Sittang, to the Deputy Commissioner, Shwegyin, No. 1-880, dated the 18th April 1885.

The question formed a subject of enquiry in the early part of the dry season in all parts of the sub-division except that where the inhabitants are Karens, which I have been unable to visit. The result of my enquiries is that salt is nowhere habitually or otherwise given to cattle as an article of food. The general reason for this is that it is not customary to give salt or, in other words, that the good effects of salt are not known. People seemed amused with the idea in most places, and asked whether it was a good thing to give salt to cattle. At Kawkaung salt was believed to cause diarrhoea, and was in fact used as a purge in cases of distension of the belly from over-eating of paddy. Everywhere it was stated the price of salt was no obstacle, and indeed, where salt can be had for almost nothing over great part of the plain, it is only 14 annas to a rupee per 10 *vis*. At Billin, which is one of the points furthest away from the salt-making region it is obvious that the salt tax has nothing in the world to do with the fact that the inhabitants do not give salt to their cattle. The people are aware that cattle like salt, and in some places use it as a bait to domesticate wildish animals, or to accustom cattle to a new home (e.g., Ayethema, Kawkaung, Zokthok).

In other places salt is a nostrum,—only one among several,—for counteracting the distressing effects of heat. Thus at Hngthak after work in the sun, a handful is put into the mouth of a bullock or buffalo "to keep the heat from going in." So at Letpanbu and Letpanbin, in both of which places after the handful has been put into the animal's mouth, a little more is rubbed over the back. The object is the same, "to keep the heat from going in." Bullocks and buffaloes are treated alike, but buffaloes are stated to be especially distressed after work in the sun. In other villages no great distance off, this medicinal use of salt was not apparently known. Thus at Talingkaw, Myingawung, Sutpann, and Kyon salt was said never to be given to cattle; it was not known of what good it would be. I may point out that the lower part of the plain, in fact the whole from the edge of the laterite ground to the sea, is saline, and that any natural craving for salt on the part of cattle can easily be satisfied without the intervention of the owners. The only water obtainable on the spot during the dry weather is very brackish, except for the muddy dregs of tank rain-water, so that perhaps cattle have more salt than is even good for them in this region. The Karens are said to give salt to their animals but I have not met with any who do so.

From F. W. CADANES, Esq., Assistant Director of Agriculture, British Burma, to the Secretary to the Chief Commissioner, British Burma, Land Revenue and Agricultural Department, dated the 23rd April, 1885.

With reference to your letter No. 2298-190, dated the 18th October 1884, I have to say that I made the enquiries with reference to the consumption of salt by cattle, suggested in the above letter, at the following places, namely, near Mr. Addie's farm at Moulmein, at Kyauktan, Pada, Naungwin, Shwebank, Maubin, Chyenghat, Bengel, Shwelaung, Thabaung, Ngathalinggyaung, Kyunpaw, Aungmye, Neikban, Henzada, Kondebia, Daunggyi, Inzeik Daunggyi, Daunggyi Thanbyadaling, Khyetkyan, Neawun, Nyauungyo (cattle are bred at Nyauungyo), Bokohaw (near Monyo), Myanaung, Kyungale, Thadagyi, and at Kama. At all of the above-mentioned places the enquiries were made of Burman cultivators, and at the places mentioned in the Kyauktan sub-division of Madras cultivators also, with the result that not one gave salt to their cattle with the exception of cases of sickness, when the Burmese gave salt and water, and the Madras one gave salt and kerosene-oil.

I have noticed the cattle fighting among themselves to get to a salt lick near Ngathalinggyaung on the right bank going up the Ngawun, and at another place near Aungmye, and have also recently heard of another lick near Okpo (Henzada). These are the only salt-licks that I know of in Burma. But I believe that they must exist in the hills opposite Ngathalinggyaung. I know of none in the delta proper. I have taken an interest in the subject of this letter since 1878 while in Tirhoot (Bengal), Ghazipur, North-Western Provinces and in Purneah (Bengal). In neither of these places do I believe it is necessary to give salt to cattle as there are plenty of earth salts to be had by the cattle, and so far as I have been able to judge, they prefer earth salt to the pure salt. This remark is applicable to both wild animals as well as domestic, with the exception of birds, such as doves, which prefer the pure, refined salt. Salt is given in America regularly, except in the neighbourhood of good licks, which are rare in the Eastern States. It is generally given once a week, and about two tablespoonfuls per head are given.

INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA :—SATURDAY, AUGUST 8, 1885.

[No. 32.]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING JULY 29, 1885]

General Remarks.—Rain has fallen in varying quantities throughout the Madras Presidency, but more is wanted in Bellary, Tanjore, and Madura. General prospects are fair, and have improved in Bellary and Anantapore; in Madura prospects are reported to be discouraging. Harvesting continues in some districts. From Mysore the reports are less favourable than last week: more rain is much needed for recently sown dry crops and for tanks. Good rain is reported from Coorg, where prospects are satisfactory.

In Bombay good rain has fallen in most districts, but more is wanted in parts of Khandesh, Nasik, Poona, Bijapore, and Sholapore. *Kharif* sowings are in general progress throughout the Presidency, and transplanting operations have commenced in places. There has been rain throughout the Berars, the Nizam's Territories, and the Central India and Rajputana States, and agricultural prospects are on the whole promising.

In the North-Western Provinces and Oudh rain has been abundant, and the prospects of the autumn crop are good. In the Punjab and in the Central Provinces good rain has fallen. *Kharif* sowings are in general progress in the former Province, and have been completed in the latter, where transplanting has commenced.

In Bengal good rain has fallen during the week, except in parts of the Burdwan and Presidency Divisions, where more rain is wanted for the transplanting of late rice. The prospects of the autumn crops and of sugarcane are good, and a fair outturn is expected from the early rice and jute harvests, which are in progress in Northern and Eastern Bengal. In Assam the weather is seasonable, and the state and prospects of the crops are good.

In British Burmah ploughing, sowing, and transplanting are in progress.

Cholera is chiefly prevalent in the Madras and Bombay Presidencies; in other Provinces the public health is generally fair.

Prices are fluctuating in the Punjab, but are generally steady elsewhere. From Bengal no material change is reported.

Madras.—General prospects fair; improved in Bellary and Anantapore; in Madura reported to be discouraging.

Bombay.—Good rain in most districts; more wanted in parts of Khandesh, Nasik, Poona, Bijapore, and especially in Sholapore. Young crops injured by insects in parts of Hyderabad and Upper Sind Frontier, and by rats in parts of Kurachi; scarcity of fodder in parts of Nasik, Sholapore, Ahmednagar, and in Panch Mahals. Cholera in parts of seventeen, and fever, small-pox, and cattle-disease in parts of seven districts.

Bengal.—Good general rain during the week, except in parts of the Burdwan and Presidency divisions, where more rain is wanted for the transplanting of late rice; elsewhere transplanting is proceeding well; prospects of autumn crops and sugarcane continue to be good; harvesting of early rice and jute progressing in Northern and Eastern Bengal, and a fair average outturn is expected. No material change in prices. Public health generally fair in Bogra, Rungpore, Rajshahye, and Serajgunj. Several slight shocks of earthquake have been felt since the severe shock of the 14th instant.

N. W. Provinces and Oudh.—Rainfall has been abundant, and *Kharif* prospects are promising. Some damage has been caused by heavy floods in the Farrukhabad and Aligarh districts. Prices are generally steady; and public health good. A few cases of cholera are reported from Gorakhpore, Allahabad, Ballia, and Jhansi.

Punjab.—Rainfall almost general. Health generally good, with exception of a few cholera cases in the Rawul Pindi city. *Kharif* sowings in progress; prospects seem favourable. Prices of food-grains rising in the Jullunder, Rawul Pindi, and Peshawar districts, falling in the Ferozepore district, stationary elsewhere.

Central Provinces.—Weather seasonable. Agricultural prospects continue good. Cholera continues in Raipore and Jubbulpore. Prices steady.

British Burmah.—Cholera severe in one district, slight in nine districts; small-pox slight in one district, elsewhere public health good;

cattle-disease severe in one district, slight in six districts, elsewhere health of cattle good. Ploughing, sowing, and transplanting progressing. Rains seasonable.

Assam.—Weather warm. Reaping of *dumali*, *murai*, and transplanting of *sali* crops progress. Common rice 14 seers 8½ chittacks per rupee. Tea doing well. Three deaths from cholera from Hallakand and three from Lakhimpore reported; general health good.

Mysore and Coorg.—Reports less favourable than last week; more rain much needed for recently sown dry crops and tanks. Public health fair; cattle-disease continues in parts. Prices stationary.

Berar and Hyderabad.—Weather rainy. Crops in good condition. Wheat 22 and *juari* 2½ seers per rupee, general health good.

Central India States.—Weather cloudy. Prospects and health good. Prices stationary.

Rajputana.—Wells and tanks full. Prospects good. Health good. Prices falling. Heat moderate; easterly winds; weather cloudy.

Nepal.—Total rainfall 27.29. Rain is now required. Weather very hot. Cholera continues. Transplanting of rice on high lands stopped for want of rain.

Letters to the Editor.

THE AGRI-HORTICULTURAL GARDENS, ALIPORE.

TO THE EDITOR.

SIR,—There was a time when these gardens held the foremost place among Indian Gardens. It belongs to the Agri-Horticultural Society of India, and is so beautifully situated, that I believe it could be made to assume almost any style. The soil is all that can be desired. There is no lack of water, and the large trees are in quite sufficient numbers to give a splendid appearance to the landscape. After some years, I paid a visit to these gardens, and was surprised to see the change that had taken place in their general appearance. It struck me as being in a sad state of dilapidation, with the rank grass growing everywhere, and choking up everything. There seemed to be a deserted air about them. As you enter and turn to the right, you are confronted by a mass of ugly *sida* flowers, not even of the superior kind. The bed of roses, right in front, as you enter, seemed neglected and overgrown with weeds. The plants were about as poor specimens as the "Queen of Flowers" as it has been my lot to see. They not only looked sickly and uncared for, but a few of them only had labels with names on them, and some of these were wrongly labelled. The bed of *Marcehal Niels*, instead of having supports for the plants (it being a climber), was overgrown with weeds, and the stems straggling upon the ground. The flower-beds along the walk, instead of having specimen plants and season annuals, were overgrown with grass and disfiguring weeds. The clumps of Palms and other plants seemed in a neglected state, the group of *Eugenia* presenting anything but a healthy appearance. Marvelling at this state of things, I went further on towards the plant houses. The new house—I do not remember to have seen it before—was the only place worth seeing in the garden. Although I did not approve of the design of the house, nor yet of the flat roof, it seemed to be looked after. The old house, I found, had been relegated to a nursery for the rarer kinds of potted plants. There seemed to be no sort of order or method about the place, and the cause of all this was not far to seek. I came to know that the Society have no *European Gardener*. It appears that there has been no such personage for the past two years or more. A native "clerk," it seems, on Rs. 50 per mensem, is the only superintending authority there is. It will be easily understood that in a garden like that of the Agri-Horticultural Society of India, a native "clerk" cannot be expected to supervise such a place with anything approaching efficiency. It is strange that

while the Agri-Horticultural Societies of the N.-W. Provinces, the Punjab, and Madras, have trained European Superintendents for their gardens, that of India should have none! Speaking to a friend on the subject recently, I was told that the Deputy Secretary, Mr. Blechynden, Junior, who is acting for the Secretary, is supposed to hold the dual post of Superintendent and Secretary, and that he resides in the Gardens, so that he may be able to superintend it more efficiently: that Mr. Blechynden, Junior, was a really clever man, and knew his business thoroughly. This is all very well, so far as it goes, and I have not the least doubt of Mr. Blechynden's abilities; but the duties of a Secretary are so onerous, and take up so much of his time at the office, that he can scarcely be expected to bestow that attention on the Gardens which is so necessary for its well-being. It requires a good gardener to devote himself exclusively to the work of the Gardens to obtain anything like satisfactory results. I have visited the Gardens at Lucknow and Lahore, and the European gardeners assured me that it was as much as they could do to efficiently superintend their respective charges. I presume that the funds of the Agri-Horticultural Society of India are in a flourishing condition. The list of members is very large; and I believe the revenue realised by the sale of plants and seeds reaches a respectable figure. There is, therefore, no reason why the Society should not have a European Superintendent for their Gardens. I would, therefore, through the medium of your journal, invite the serious consideration of the President of the Society to this subject. It is a pity that the Gardens should suffer for the want of proper supervision.

A VISITOR.

Editorial Notes.

ELSEWHERE will be found a letter regarding the Agri-Horticultural Society's Gardens at Alipore, to which we direct the attention of the Secretary. Our correspondent has seen the gardens at an unfavourable season of the year, when the growth of rank weeds and grasses can scarcely be kept down. As for the rest, we do not know how far our correspondent may be correct, but the want of a European superintendent would, we should think, be much felt in a garden such as that of the Agri-Horticultural Society at Alipore; but probably the Society have some very good reasons for what they are doing.

WE learn that a memorial has been addressed by the Bombay Presidency Association to the local Government, in support of the prayer preferred by the Tanna memorialists against the Forest Department that the questions in dispute may be preferred to a mixed Commission composed of independent official and non-official gentlemen, European and native, enjoying public confidence, as the "best means for furnishing the materials to elaborate a new and improved forest system, which, while duly conserving the rights of the public, will not press upon any class of the community." Lord Reay, in his speech at Poona, replying to the address of the Sarvajanic Sabha, stated that a Commission had been appointed for this purpose.

INDICATIONS are not wanting that Lord Reay's administration of the Bombay Presidency will mark an era in the history of the people. A Resolution is published in the *Bombay Government Gazette*, dated July 20th, directing that "the forest regulations, whilst preserving the public interests, should be equitable, and liberal in dealing with private interests." The way in which State interests in our forests have been asserted within our own knowledge, would have produced a rebellion amongst any other people, not only for their ruthless disregard of immemorial rights and usages, but for their positively confiscatory character, as in the case of the Raja of Shushang. We are hoping that Lord Reay will interest himself in the silver question. Our readers may remember that he was one of the English delegates at the Paris Conference of 1881, with Sir LOUIS MALLET.

WE are glad to learn from a contemporary that the Bombay Government has appointed a Commission to enquire into the grievances of the people, especially in the Tanna district, from the operation of the Forest Laws. The Commission is to

consist of four Europeans, and three Natives, the Collector of Tanna being the Chairman. "The labours of the Commission will be mainly directed to hearing complaints, ascertaining their reality, and considering the best manner in which provision can be made for supplying the wants of resident agriculturists, as distinct from the trade demands. The Commission will also consider the situation of the hill tribes, in regard to forest regulations; and the suggestion of means whereby the regulations of the Government may best be made intelligible to the people."

For the last ten years have the people been complaining bitterly of the oppression of the Forest Department. In many cases, the wrong has been so obvious that it was not enquiry, but redress, that was wanted. We are glad to see that the remonstrances of the people in Western India have at last forced the attention of Government to the subject, but it would have been better to have instituted these enquiries before the people were exasperated to the verge of rebellion.

WE find that the total capital outlay on irrigation works in Sind, up to the end of the year 1883-84, was Rs. 1,01,13,681, of which Rs. 67,74,709 had been spent on productive works. The actual revenue from all sources was Rs. 28,10,861, whilst the expenses for maintenance and collection amounted to Rs. 14,07,958. On the canals which are classed as productive, the earnings give a percentage of 4.60 on the capital invested, whilst the return from those works for which capital and revenue accounts are kept was, according to the figures, 15.06 per cent. The area cultivated by the aid of the irrigation works was 1,540,831 acres, the revenue from which was Rs. 31,68,358, or nearly Rs. 2.33 per acre. Even this rate is expected to increase, as the people are beginning better to appreciate the benefit of the canals.

THE following, which we take from the *Farmers' Review*, ought to be noted by grape-growers:—Those who have been troubled with their grapes rotting on their vines should now lose no time in bagging them. For this purpose, the paper bags used by grocers, and which cost but a trifle, are used. A good size is 8 by 6 inches. The open mouth of the bag is slipped over the cluster, gathered in around the stem, and fastened with a pin. It is left on until the grapes are ripe. No rotting of grapes so bagged has ever been reported, while clusters on the same vines not thus protected have been ruined. The philosophy of the protection is this: The rot is caused by fungoid spores floating in the atmosphere, which attach themselves to the clusters and cause the rot. The paper bag serves as a perfect protection, and curiously enough, the grapes develop larger, firmer, and of better quality than those not so protected, even when not affected with rot. Grape growers who have gone into the bagging business extensively, claim that leaving the rot entirely out of the question, it pays them in the superior quality of the fruit, and the extra price it commands in the market.

WE are told that the object of the Conference between Mr. Buck, Secretary to Government in the Agricultural Department, Colonel Wace, Mr. Smeaton, and Mr. Fuller, Directors of Agriculture in the Punjab, the North-West, and Central Provinces, was to decide on the final proposals for the formation of a Civil Veterinary Department. It appears that Lord Hartington, when Secretary of State for India in 1882, urged upon the Government of India the advisability of establishing a Civil Veterinary Department throughout India, to cope with the diseases which destroy such large numbers of cattle annually. And Lord Kimberley more recently advised that a portion of the Army Veterinary Staff should be transferred to the Civil Department. The scheme which is now being elaborated will, it is stated, include the formation of a Civil Veterinary Department in every province, and there is some probability of Military Veterinary Surgeons being lent during peace time to superintend provincial operations. Madras has a Civil Veterinary Department already, with Mr. Mills at its head, who has been devoting much attention to important experiments in the treatment of cattle diseases.

The question of establishing a Planters' Provident Fund has been discussed before, but the subject does not seem to have been taken up with any degree of heartiness. The matter has been recently revived, and the *Madras Mail*, in referring to the subject, says:—"There can be no doubt that the benefit to planters of such an institution would be very great. As the promoters of the proposed fund profess not to be bound to any particular mode of action, but to be desirous of joining all the different planting interests in India, the preliminary steps ought to be taken as soon as possible to plan out the scheme. Our contemporary (*Indian Planter's Gazette*) points out that 'planters by combining can secure for themselves all the benefits of a first class Assurance Society, and in addition can retain not some, but all, the profit which no Assurance Society in existence can give them. There is not a village in England, nor a clachan in Scotland, which has not a Friendly Society of some sort, and it says very little for the planting enterprise of India that up to the present time no combined effort for mutual help has been made.' The precise lines on which such a fund ought to be conducted cannot of course be indicated off-hand, and must form a subject of discussion amongst the planters themselves."

**

A somewhat friend in the Mofussil, who is competent to speak on the subject, tells us that his belief is, that a line drawn from the south-east of Java to the north-west of the Caspian, forming an arc of about 80 degrees on the earth's surface, and of which line Calcutta occupies the central spot—being 40 degrees from either extremity—indicates the main line of volcanic action in Asia. Along this line, and as far as 5 degrees on either side of it, earthquakes may occur at any time; their severity being generally greater in proportion to their nearness to the extremities of the zone, and less as they approach the middle, where an enormous thickness of the earth's crust has been depressed. Hence Cashmere and Tenasserim are more likely to suffer from earthquake than Calcutta. But there are some exceptions to this general rule, according as the subterranean gases and electricity are conceived to be more or less active, beneath any given locality. For instance, Simla is thought to be in greater danger than Chumba; and Tehri (Gurhwal) more than either. It is surmised that some severe shaking will be felt before long in the southern part of the Malayan Peninsula. Our informant holds that the inhabitants of Calcutta have far more to fear from inundations, than from earthquakes; and he suggests the construction of *protective dykes*, as a security against the too probable storm-wave.

**

We print elsewhere *in extenso* the report on experiments at Alon, submitted by Mr. R. Romanis, Chemical Examiner, British Burmah, dated 29th May, 1885. As far as we can make out, the experiment with chemical manures does not seem to have resulted as favourably as might have been expected. The tabulated statement regarding the outturn of grain and straw, is a little obscure. It is not stated whether the figures mean lbs., cwt., tons, or maunds; but we presume they are intended to represent lbs., as there is an allusion made in the paragraph immediately following, about an "increase of 250lbs." The jute cultivated was a failure, for it is said that "very little of it was fit for making fibre." So likewise, was the sorghum, the juice of which contained about 17 per cent of solid matter, of which only half was crystallizable sugar. "The juice when evaporated gave a dark treacle of a bitter taste." Mr. Romanis does not think sorghum is suited to Burmah. He says it is not so rich in sugar as Sugarcane, and the manufacture of sugar from it requires far more skill. He adds that although it is true it occupies the ground for only four months, it is the same time as rice, and there appears to be no advantage in replacing rice by sorghum. That the cultivation of sorghum in the United States is the result of protective duties, and that it has there taken the place of maple sugar, but under natural conditions. He does not think it could compete with sugarcane, and is of opinion that it seems unnecessary to make any further experiments with sorghum. The working expenses of the experiment amounted to Rs. 254-11.

Two uses of paper, as we know, are many and varied. Another use has, however, been found for this material, viz., "paper faces" for clocks. The *Paper-Makers' Journal* has the following on this subject:—"The manufacture of cheap clocks and watches has come to be one of the great industries of the United States. A prominent engraver there recently mentioned that several years ago officers of the Assonet Clock Company came to him to know if he could not make an engraved paper imitation of the French porcelain face that was then used on their clocks. He spent several hundred dollars in the experiment, and finally gave it up in despair, through inability to find paper that would answer the purpose. The Company refused to let him stop his experimenting, and he finally hit on a glazed and enamelled paper, which answered the purpose. He has made 12,000,000 to 14,000,000 clock faces for the company at a cost of about one cent each. The old cost for porcelain was a dollar, which is the present cost of a clock complete. Machinery has been specially invented for turning out the paper faces. This circumstance is a fair instance of American ingenuity, persistency, and invention."

**

At the present time, when there is so much controversy going on respecting the silver question, our readers will be interested to learn that Count Wolewski, an eminent French financier, at one time Minister of Commerce under the Empire, predicted as follows on the subject of the demonetization of silver:—

"The demonetisation of silver by any great civilised nation must produce the following results:—1. The international trade of the world will instantly show signs of decline, to the special injury of countries having the largest international trade.—2. The spirit of public enterprise in railroads and other useful undertakings will be checked, and consequently the general progress of civilisation will suffer.—3. The decline in prices will compel countries internally to depart more and more from the principles of free trade towards a policy of protection.—4. The nations will be divided into two groups, the one trading on gold, the other on silver, and this will render commerce between them unsafe and precarious.—5. Throughout the world a decline in prices will follow, injurious alike to owners of real property and the labouring classes, and advantageous only, and unjustly so, to the holders of bonds and similar securities.—6. One of the principal difficulties in this period of general depression will be, that people will look for its causes in all possible directions. The advocates of the gold standard will offer all possible groundless and fantastic reasons of a secondary nature only, and the real cause, the demonetisation of silver, will be overlooked, until the perpetuity of the phenomenon and dire necessity shall force thinking men to point it out."

Needless to say that these predictions have been fulfilled.

**

A COMMITTEE has been appointed by the Madras Government to report whether any of the buildings at the Saidapet Farm could be made available for the use of the Veterinary Hospital. It appears that there are no stalls available for the Veterinary Hospital in any of the farm buildings, and Messrs. Benson and Robertson both object to the conversion of any part of the building now used for the accommodation of the farm stock, into stables for the hospital; their grounds being that it would be dangerous to locate any of the stock required for the working of that part of the farm, which is to be an annex to the Agricultural College, anywhere near where animals suffering from contagious diseases are likely to be placed, or in the neighbourhood of a building where dissections are to be carried on. There are other objections, more or less valid, to the present farm stables being made over to the Veterinary Department. The gentlemen consulted in the matter being all professionals, and their several opinions not being unanimous on all the points at issue, the Officiating Director of Agriculture and Revenue Settlement has suggested that a Committee composed of Mr. J. H. Garstin, as President, with Messrs. Robertson, Shaw and Mills, as members, be appointed to enquire and report—

I. Whether any of the existing buildings at the Government Farm can be employed or converted to use as stabling and a

dissecting shed for the Veterinary Hospital, and, if not, what valid objections to doing so exist?

II. Where, if using any of the existing farm buildings for the purpose mentioned above, is deemed undesirable, the new stabling and dissecting shed should be built?

III. What should be the extent and character of the extra accommodation to be provided, and what its approximate cost?

IV. Whether there is any valid objection to the retention, in their present position, of the buildings forming the existing Veterinary Hospital?

This proposal has been sanctioned, and we shall await, with some interest, the report of the Committee.

We take the following statistics regarding British exports and imports of paper from the *Paper Makers' Journal*:—Our exports of paper still show an increase, though other articles of home manufacture are exported to a smaller amount than a twelve-month ago. During April there were shipped from the United Kingdom 72,078 cwt. of paper, valued at £147,008, as compared with 60,198 cwt., valued at £128,282, in the same month last year. A corresponding advance is noticeable in the outward trade done during the first four months of the year, the actual export having been 268,338 cwt., valued at £561,148, against 241,427 cwt., valued at £524,308, at the same date last year. The import returns show, however, that an increased quantity of foreign paper has found a market in the United Kingdom during April, the imports having amounted to 116,242 cwt., valued at £102,571, as compared with 110,236 cwt., valued at £108,727, in April, 1884. While the quantity has augmented, there has been a decrease in value, which would seem to show the continually diminishing price of foreign paper. The imports for the four months compare, on the other hand, advantageously in favour of the current year, the figures for which are 427,491 cwt., valued at £401,252, against 402,248 cwt., valued at £443,567, at the same date a twelve-month ago. The above totals are exclusive of the re-exports of foreign-made paper. In stationery there has been a contraction of the foreign demand during the four months. The export figures for the first four months of the year represent a value of £252,039, against £260,748 a twelve-month ago. Australia is the only country with which our foreign trade in stationery has increased, as compared with 1884, and even here the increase has been very slight.

It seems that the colony of Trinidad is not as bad as it has come to be regarded. *The Colonies and India*, writing on this subject, says:—"Mr. Prestoe, the Government Botanist of Trinidad, at the request of the Tobago Agricultural Society, has just paid a visit of inspection to Tobago, where several estates have lately gone into liquidation, with a view to suggesting some form of cultivation which shall replace sugar. He has expressed himself as greatly surprised at finding the island so different from what casual reports had led him to expect, and he declares that it is superior in natural advantages to either Grenada or St. Lucia. Be that as it may, he saw on his tour round the island, tracts of land which, as he expressed it, 'seemed to have been formed especially to grow cocoa,' alongside of other tracts, abundantly watered, which he described as 'magnificent cane-growing land, on which central factories ought to be established.' His formal report will shortly be issued, which we expect will help to dispel the unaccountably bad impression which prevails about the colony; but in the meantime an effort is being made to form a company to take up one of the recently sequestered estates for the purpose of adopting Mr. Prestoe's recommendations. An estate of about 2,300 acres, together with all the machinery, buildings, and live stock thereon, is to be purchased for 4,000*l.*, or little more than 1*l.* an acre—one-half to be paid at once, and the rest in two years. How many men are there in this country who would be glad to purchase such an estate at such a price, for mere purposes of recreation! Properly handled, such a property ought to yield an enormous profit, for even under sugar cultivation the land is really worth ten times the amount proposed to be paid for it. The venture will be before the notice of investors simultaneously in the West

Indies and in London, and there ought to be no difficulty whatever in raising the money. If the such venture succeeds, the chance of buying up another such an estate on such terms is hardly likely to occur."

We are told that the Government of India are taking in hand the question of improving the Indian wheat trade, both in regard to care in cultivation and increased facilities of carriage to ports of shipment. The Bengal Government has been called on for its opinion upon the points which have already been discussed in Bombay, the North-Western Provinces, and the Punjab; and the Lieutenant-Governor has referred the matter to the Director of Agriculture for report. Bengal is mainly interested because of the position of Calcutta as a port from which wheat is shipped in large quantities, but there is some wheat grown in Behar, and the proposals in regard to improved cultivation might perhaps be usefully applied there. The Government is at present extremely ignorant regarding wheat cultivation in the provinces, which illustrates how necessary it was that some such official connection with agriculture, as that provided by the newly-formed Agricultural Department, should be established. The Lieutenant-Governor "fears that anything like accurate knowledge of detailed statistics of the cultivation and trade in wheat in these provinces is as far from attainment at this moment as when inquiries into this branch of the subject were first set on foot in 1879," and does not think his Government will be in a position to prosecute such an inquiry with any reasonable hope of success "till village establishments are organised in Bengal." But his Honour desires that meanwhile the Agricultural Department will collect accurate knowledge on the subject, as far as lies in its power, and disseminate any information that may seem likely to be of practical use. Calcutta is interested in the ventilation of the question to the extent that some of the proposals made contemplate the sorting and weighing of the wheat up-country, and its delivery immediately from the railway waggons on board ship, without any necessity for examination and weighing here.

The *Paper-Makers' Journal* notices a new material to which the name *Agalite Fibre* has been given. It is intended to improve the colour and finish of papers without the necessity for extra rolling, and from the samples sent to our contemporary, he is disposed to endorse the declaration made on its behalf, that it is likely to be acknowledged by paper-makers as a *succedane* rather than as a loading for paper, and superior to any substance of the kind heretofore used for that purpose. At all events, the testimony of paper-makers who have already proved its merits is set forth briefly and emphatically by Messrs. G. F. Green & Co., of 3, George-yard, Lombard-street, who are the sole agents for the *Agalite Fibre* in the United Kingdom. The fact of its being called a *fibre* is significant, and as it is claimed for it not only that its fibrous nature can be discovered under the microscope, but that this quality causes it to adhere to the pulp, so that 90 per cent of the material is retained in the paper, the characteristic may well be regarded as an important one, especially as it is averred that the *Agalite* is a substitute capable of taking the place of straw as a *succedane*. It is stated that the backwater from the machine where this material is used, passes away almost clear, and that the fibre itself is absolutely free from grit, sulphur, iron, and lime, and is therefore above comparison with other mineral substances, used for a similar, or rather, for an inferior purpose. There are two preparations of the fibre—one coarse, the other fine, and Messrs. G. F. Green & Co. are now prepared to forward bags of from 900 lbs. to one ton weight, so that paper-makers may make trial of a sample. It is understood that members of the trade who have tested its remarkable qualities have repeatedly and largely increased their orders, and that it is being actively introduced to foreign manufacturers, so that as it is to be obtained from only one mine, Messrs. Green & Co. are naturally desirous of bringing it before the trade in England.

The following facts about race relations in the United States, which we take from the *Planter's Gazette*, are interesting:—The

The Madras Government, in passing orders, have laid down the following ruling—The Government agree with the Superintendent of Revenue Survey as to the nature of the Survey Test which Revenue Inspectors should be required to pass, and are pleased to direct that, from or after the 1st April 1898, no person who shall not have then passed such test shall be eligible for appointment as a Revenue Inspector, or for promotion to the new rates of pay, or to a higher grade. In the case of officers who are now Revenue Inspectors, the Government are of opinion that they should be attached on duty—as Assistant

Collections now are—to a survey party for a period not exceeding six weeks in any case. When and what number of officers shall be allowed to go for instruction may be left to Collectors to decide. Arrangements should be made, however, to meet the reasonable requirements of all officers wishing to qualify. Persons not already in the service, nor in the grade of Revenue Inspectors, must make their own arrangements for instruction in surveying, unless the Collector certifies that he wishes in any particular case that a man, whether in the service or not, should be attached for instruction in view to appointment as Revenue Inspector. Any person not so designated by the Collector, but who is already in the service, may, as the Board suggest, be reasonably required to avail himself of some period of authorized leave for the acquisition of the special knowledge. No person should be admitted by the Survey Department for instruction without a certificate from the Collector, and where the person is not in the service already, except on a payment of a fee of Rs. 5. The fees thus collected will be credited to Government. No fee will be exacted from officers already in the service of Government. The examination should be conducted by Deputy Superintendents of Survey in the districts, who will grant certificates of qualification. Such certificates should be forwarded for information and record to the Collector's office.

ENSILAGE vs. GREEN FODDER.

I.

LAST week we published a letter from Mr. D. B. Allen, of the Bengal Agricultural Department, upon this subject, in which he endeavoured to show that the generally received opinion that ensilage was superior to fodder in its green state, was erroneous, and was to be received with caution; and he quoted Dr. Aitkins' remarks in support of his argument. We had taken the liberty of commenting upon his previous paper, "Hints on Ensilage"—and it was in answer to these remarks that Mr. Allen addressed us. We do not for a moment wish it to be understood that we regard *all* ensilage fodder to be superior; we are chiefly concerned with the production of silage *as it should be*, in accordance with the principles governing the process, which has created such a revolution in the feeding matter of stock. We are firmly convinced that silage, properly prepared, possesses qualities superior to ordinary fodder in its green state; and in this opinion we are borne out by the testimony of many qualified persons, in a position to speak with authority on the subject. The *practical* results obtained by feeding cattle, &c., on silaged fodder prove conclusively its superiority over the green article. We shall, in this paper, quote our authorities in support of this view.

Not to go very far back, or indeed very far from Calcutta, we shall instance the ensilage experiments carried out under the direction of Brigadier-General H. C. Wilkinson, G.B., Commanding the Presidency District, during 1884. In his "notes" the General says:

"Ensilage has been found by experiments to be more fattening and nourishing than green grass, and cows fed upon ensilage give more milk, and their milk yields more cream, than when they are fed upon grass."

He then refers to sweet ensilage, which is really what Mr. Fry has striven to explain in his very important work. General Wilkinson says:

"A little partly-made sweet hay is put in the bottom of the silo (to not as yeast does in bread-making), green forage is then lightly loaded in on the top of the partly made hay to the depth of about a yard, this is not pressed down or trampled, so that strong fermentation sets in at once. As soon as a temperature of 122° Fahrenheit is reached, the forage is firmly trampled down, the "bacteria" of sour fermentation having been destroyed by this heat. More green forage is now added to the depth of another yard, and the process is continued as before till the silo is quite full, when it is covered over like any other silo."

"If every portion of the contents has been duly heated to a temperature of 122°, the result will be ensilage as sweet as good old hay."

With regard to the feeding qualities respectively of ensilage and green grass, the following table, supplied to us by General

Wilkinson, will speak for itself. We have no reason to doubt the accuracy of this statement:—

Table showing the comparative value of green grass and ensilage as a fattening, nourishing, milk and cream yielding food.

GREEN GRASS.

No. of Cow.	Date of Experiment.	No. of Days.	Weight.		Yield of Milk.			Quality of Milk.

Total	112	0	106	613 0	0	28 11	10

N. B.—The quality of the milk is indicated by figures. 0 represents absolutely skim milk, and 30 represents pure, thick cream; thus the higher the figure, the more cream there is in the fresh milk.

2. It will be seen by the "Weight," and "Yield of milk," columns, that all the gain in weight and increase in yield was due to the ensilage, and all the "loss" to the green grass, though the time of year was most favourable to green grass.

We direct particular attention to the note at the bottom of the statement, especially 2. With these results before us, it seems scarcely necessary to pursue the subject further, in order to prove the superiority of ensilage over fodder in its fresh, green state. Whatever may be the results, so far as scientific experiments are concerned, and whatever may be the opinion of chemists from a theoretical point of view, the proof of any system can only be obtained satisfactorily by a practical application of it. To quote a hackneyed phrase, "The proof of the pudding is in the eating of it." We remarked, some three months back, in reference to these very experiments, that—

"It would be almost too much for one's credulity—were the facts not vouched for—to be told that two cows when fed on ensilage for 28 days gave an increase of as many scores of milk, and two similarly fed on grass, decreased by 80 scores of milk in 28 days!"

Theories are all very well so far as they go; but if they cannot be borne out by facts and by practical tests, they fall to the ground. So far as the farmer is concerned, it has been abundantly proved that in almost every instance where stock were fed on ensilage, the results proved the superiority of silage over fodder in its green state. We could quote the testimony of innumerable individuals, European and American, including the evidence of members before the Royal Ensilage Commission, in support of our views; but Indian testimony seems to us to have most force. In our next, we shall treat the subject from a theoretical point of view.

CULTIVATION EXPERIMENTS IN THE ARAKAN HILL TRACTS.

MR. F. C. FANSHAW, acting Deputy Commissioner of the Arakan Hill Tracts, has submitted an interesting report on experimental cultivation of certain economic products in these outlying tracts, but the results obtained by him do not encourage the hope of bringing these remote regions, peopled by ignorant savages, within the pale of civilized cultivation of useful products for the market.

There are two gardens in which these experiments were carried on; one at Paletwa and the other at Kyoukpaung. A sum of Rs. 1,000 was allotted for the year 1884-85, of which Rs. 880 were expended. Since the last report was submitted in May 1884, the gardens do not show any marked improvement. The money is chiefly spent on gardeners' wages and coolie hire, as it is found very difficult to keep the gardens free from weeds and grass during the rains, and nearly half the allotment is spent on coolie hire for this purpose.

The Paletwa garden occupies an area of $4\frac{1}{2}$ acres. Its situation is unfavourable, the ground being low and swampy in some parts. The *Tea* plants here are said to be looking healthy, and have been leased out for one year for Rs. 100. The *Potatoes* proved a failure; but this was owing chiefly to the seeds having arrived in a bad state; another reason being that they were not planted as they should have been, i.e., in light, sandy soil, and on ridges; but were sown on heavy soil, on low ground, and in trenches. In a country possessing a naturally humid climate, with a heavy rainfall, this result was to be expected under the circumstances. Mr. Fanshawe, however, is of opinion that the experiment is worth trying again this year. The *Pepper-vine* seems to have done fairly well, and it is intended to plant it extensively on the Burmese method of growing betel-vines. The *Cinnamon* has been a complete success, and "a small forest of them" is said to exist at Kyoukpaung. The variety of *Coffee* grown was the Liberian, and the plants appear to have done well. The *Arabian coffee* was also tried, but it did not get on well. *Manilla hemp* is said to get on well, and the same is said of the *Betel-vine*. Two *Cocoa* trees have reached the height of 9 and 4 feet respectively, and may be pronounced a success. There are no *Sugar-canes* in the Paletwa garden, but Mr. Fanshawe thinks it would pay to plant them. Among *Fruit*, the *Mango*, the *Plantain*, and the *Pine-apple* are mentioned. The last-named is said not to do well. An important feature in the report is the remark about *Khaki cotton*. A little of it is grown for home consumption, but very little is exported. Mr. Fanshawe thinks some seed might be given to the cultivators as an experiment, as the price is double that of white cotton; and that when the peasants find that it will pay well, they would probably take to cultivating it regularly. The Chief Commissioner has sent seeds to Mr. Fanshawe, and we shall be glad to hear the result of the experiment. There were no new experiments during the year.

Mr. Fanshawe, we regret to see, does not seem to take a hopeful view of the utility of the garden at Paletwa. He says:

"The experimental cultivation in the Arakan Hill Tracts has done little or nothing, I am sorry to say, to induce the peasantry to try new products, and I am afraid that, as long as they live the life that they do at present, they will never attempt anything new. Their staple products are of course rice and sesamum for home consumption, and tobacco and cotton for both home consumption and export. Their time is pretty well taken up in their taungyas and tobacco fields, and the month or two in which they have nothing to do they spend in a series of feasts. The ground used for the cultivation of tobacco could not be used for permanent garden

land, as it is all under water during the rains; and, if taungyas were cut far from the water, the labour would be immense to keep the ground properly watered during the hot weather, and that is just the time that they are all hard at work cutting their taungyas for planting paddy, &c. They are too lazy and indolent to put themselves out in any way, and as long as they have enough to eat and drink, with a few rupees to spend yearly, they are quite contented. Different kinds of tobacco and cotton they would willingly sow, I think; and if Mr. Bridges supplies seeds next year, as he has very kindly offered to do, I have no doubt that the experiment will be a success.

Even if planters were induced to settle up here, I do not think they would find cultivation profitable, as the great difficulty of course would be coolie labour. The peasantry here simply would not work regularly, and all the labour would have to be imported, and even then I am afraid the coolies would be constantly down with fever, for the first year or two at any rate, and unless they were paid at ruinously high rates, they would desert whenever they got a chance.

Burmese servants are, as a rule, of the stamp Mr. Fanshawe has described, and much cannot be expected of them.

With regard to the garden at Kyoukpaung, which is of more pretensions, it may be said that *Tea* and *Cinchona* thrive well, and may be cultivated with success.

The tea garden is already assuming large proportions, and the time is coming when, with a little skilled labour for curing processes, the trees will yield a return which ought to make the garden more than self-supporting. The number of trees and young plants exceeds 12,000, and this number is capable of large extension, so as to form the nucleus of a fairly good tea estate, which would pay well in any part of the country where labour was procurable at ordinary low rates.

The fact, too, that there are over 400 cinchona plants at Kyoukpaung, all doing well, particularly the larger ones, seems to prove that the locality is favourable to the growth of this very important vegetable product.

Potatoes and *Coffee* were failures. *Fruit trees*, such as raspberry and apricot, have done well. *Tobacco* seems to have proved successful, and Mr. Fanshawe has been supplied with seed for extended experiment. The tobacco produced is said to be very good of its kind, and fetches a good price in the local market. Looking at the experiment as a whole, it may be said to have been fairly successful; but in our opinion something more than merely official supervision, such as that exercised by a Deputy Commissioner, is needed to prove to demonstration whether the results obtained cannot be improved upon. The Commissioner, Colonel Sladen, is of the same opinion, as he says—

The experiment need not for the present be repeated until the conditions are more favourable, and we can count upon more skilled supervision.

It has, however, been decided to continue the grant of Rs. 1,000 for another year. Let us hope that the results of the next year will be more satisfactory.

THE RE-SETTLEMENT OF THE CENTRAL PROVINCES.

THE result of Mr. CROSTWATER's visit to Simla is, that the re-settlement of the Central Provinces will be undertaken, without any new survey of the land. We believe the decision to be a wise one. The survey of 20 years ago was so thoroughly well done, that it is impossible to believe that there can be any necessity of a new one within 20 or 30 years. No one who is familiar with the Settlement reports of these districts, that appeared at intervals from 1860 to 1869, can forget the conspicuous ability by which they were marked. The one failing that characterized them all, was the pitching of the assessments at rates that positively mocked the necessities of the treasury. Sir RICHARD TEMPLE was permitted at the outset to lay it down as a principle, that if the Government would but give the land away, by fixing the assessments at purely nominal rates, the growing wealth of the people would cause the public treasury to overflow with receipts from the excise and customs duties. In his very first report, he gave expression to this conviction in the terms we have now employed.

So sensible did he himself become of the wild mistake that had been made, that it became impossible in after years to get a copy of this report at all. It has been distinctly affirmed that Sir RICHARD TEMPLE himself withdrew all copies of it from the records. We had a copy in our possession for some years, but having lost it, were never able to procure a second one.

The Government is now face to face with the hard necessity of doing what it can to redeem the error that was then made, by raising the assessments to rates that will relieve the rest of India from the burden which the heavy deficit in these provinces has cast upon their shoulders. They are already in arrears to the public treasury to an amount of money that we shall never be able to recover from them now, but the assessments must be raised in the new settlement to rates that will at least relieve the other provinces from carrying this burden any longer. If Mr. CROSTHWAITÉ finds it impossible to raise the rates to their proper level at one stroke, he must at all events make a substantial beginning, and must in that case issue no leases with a longer currency than ten years. The thirty-years' lease system has become an error everywhere owing to many causes. The growth of an entirely new export trade, the immense outlay that has been made upon the railways of the Centre Province, and the great change that has taken place in the value of money in the last twenty years, make it impossible to think of any renewal of the expiring leases upon the old terms. Mr. Crosthwaite's long experience and ability, peculiarly qualify him for the work he has to do, and we believe he may be trusted to hit the right mean. He sees now in 1885 as clearly as ourselves, the profound delusion of the views under which settlements of 1860-69 were made. Our fear is that he may lack resolution to face his task with the full courage it demands. The general result of the Temple settlement has been, that the provinces have barely met their own expenditure, while they fall short of their proper share of the Imperial burdens, by nearly a million sterling a year. Now, in justice to the rest of India, the arrears and deficit that Sir Richard Temple's settlement has brought upon us, ought to be liquidated, but as that is hopeless, all that we can do is to change the aspect of matters for the future. We charge Mr. Crosthwaite to do it resolutely.

THE BENGAL TENANCY ACT.

The attention of Parliament has been directed to the passing of this Act by Lord KIMBERLEY, in the *Indian Statesman* of Saturday last, which went home by the Mail, in the following terms:—

The announcement that the Bengal Tenancy Act finally passed the Indian Council at Home on the 22nd June, when Lord Kimberley had virtually ceased to hold office, has created a feeling of profound disappointment in these Provinces. His Lordship's act was a most improper one, for he had distinctly promised that the Act should not pass the Council until he had received and weighed with attention, the memorials that he knew were being addressed to him from the various Land Associations of Bengal. He has distinctly violated his word. His lordship knew well, in particular, that the memorial of the Landholders' Association of Bengal, which is a most able and exhaustive criticism of the Bill, only left India on the 13th June; and he went down to the India Office, and signed the despatch on the 22nd or 23rd, well knowing that the Memorial was on its way; that it was the great final effort of the zemindars to save themselves from ruin; and that he had distinctly promised them that the Bill should not pass the Council, until he had seen and weighed carefully their Memorial against it. Is India really to be governed in this way? If the Bill is the wise and just measure which the outgoing Ministry declare it to be in their conviction, they might safely have left it to be confirmed by their successors. They know well how doubtful is the wisdom of the measure, and that their successors would never have passed it in its present shape, and Lord Kimberley's act ought to be disallowed, and the despatch recalled. His course reflects dishonour upon the late Ministry.

We trust very earnestly that Lord KIMBERLEY may be called to account for this conduct. He plainly signed the despatch for no reason whatever but to embarrass his successors, and if possible, to prevent their review of the Act. Englishmen are not used to such conduct on the part of their public men, and if

Parliament is still sitting when the Mail arrives, his lordship will, we trust, be called to account for his course.

Miscellaneous Items

We regret to learn that the tobacco crop at Hamsadah has been greatly damaged by insects; and that in consequence the output will fall considerably short of what was expected.

THE Kyoto Exhibition was closed on the 8th July with the usual formalities, and medals, &c., were presented to the successful exhibitors by the Governor who was in attendance with a number of the local officials. It was mentioned that 187,871 articles had been shown by 1,081 exhibitors, and that 54,481 persons had visited the building since it was opened on the 1st of last April.

The net income from manufactures in the Mercers' Jail for the past year has fallen off. This is attributed to the opposition bakeries now started outside by private speculators. Twenty-two convicts work daily at the bakery, and the grinding of the wheat is said to be work of a good penal kind, and provides hard labor for many long-sentenced prisoners, who cannot be sent to work outside. The Jail authorities, however, are willing to discontinue bread-making altogether, if a good reliable baker were to set up business.

THE ground-nut season at Pondicherry is nearly over; arrivals by rail and road are now very light, and consist for the most part of old stocks upon which advances have been made. Four vessels have lately left for Marseilles with 126,004 bags and packets; viz., the *Sir Garnet Wolseley*, 25,384; *Toledo*, 5,155; the *Naples*, 27,574; and the *Leban*, 28,004. Prices are nominally from Rs. 21-8-0 per French candy of 1ba 528 English, but the whole crop has been bought up. Up to date about 975,000 bags have been shipped, and the stocks on hand amount to some 100,000 bags more, so that our original estimate of February last, viz., of from 450,000 to 500,000, will be substantially correct. The *Saint Faziare* is now completing her loading, and will leave in a few days for Marseilles.

A TABULAR statement has been issued by the Director-General of Railways showing the position of the Indian lines constructed and in progress on the 31st of March last. The guaranteed railways had on that date 109 miles in progress and 47 miles not commenced; the assisted railways had 759 miles in progress and 40 not commenced; the State Railways Imperial 1,163 and 427; and the State Railways Provincial 420 and 108. The figures for the State Railways of Native States are 439 and 33 respectively, while the East Indian had 9 miles in progress. This gives a grand total of 2,897 miles in progress and 256 not commenced. The Bolan Railway and its extension to Quetta, with the Shebo-Khojak extension, are not included in the above return, as they were not at that time sanctioned.

A SERIOUS blow has been aimed at the indigo industry from a friendly quarter. We learn on good authority, that "for the benefit of goods manufactured in Keraia, H. M. the Shah, in 1882, issued a decree interdicting the importation into, and the sale of aniline dyes within, his territories. Information has now been received by the Government of India, that H. M. has recently placed a similar restriction on the importation into Persia of thread coloured with such dyes." The trade returns show no importation of aniline dyes to Persia during late years, until last year, when 11 cwt., valued at Rs. 1,350, were apparently surreptitiously sent to Khorasan. It is difficult to arrive at the real extent of the trade in threads and yarns, but this also appears to have been on the same scale. It would seem, therefore, as if the Shah was a protectionist of very extreme views. The total export of indigo dyes from British India is valued at Rs. 6,22,260.

THE following is an order passed by the Dewan to his Highness the Maharaja of Mysore:—The Deputy Commissioner of Bangalore reports that the drain upon the fuel resources of the Bangalore District is becoming heavy, and that the reckless felling of fuel in the district forests of that district requires some check. An economy in this respect is now of vital importance, owing to the large supply of fuel which is required by the State Railway, and for the increasing requirements of the city and station of Bangalore. He proposes the levy of a seigniorage upon all fuel felled in Government district forests and brought into Bangalore, and has recommended the following rates of seigniorages: Four annas per vadder cartload of fuel, 6 annas for country cartload of fuel, Rs. 1 and Rs. 1-8 per cartload of charcoal. These rates have been in force since 1870 in a portion of the Bangalore district, viz., in the Maralavadi forest, in the Kankeapalli Taluk. The levy of the proposed seigniorage has been sanctioned by the Dewan.

FROM a report of Irrigation Works in Sindh for 1883-84, we find that the capital expenditure during this year, 1883-84, from productive and ordinary funds, amounted to Rs. 4,42,032 and Rs. 39,594, respectively. The total capital outlay up to the close of this year was Rs. 1,01,13,681, of which sum Rs. 67,74,708 had been spent on productive Public Works. The gross revenue from all sources was by assessments Rs. 28,66,726 and by collections Rs. 2,80,561. The revenue due to irrigation works other than agricultural was by assessments, Rs. 25,66,186 and by collections, Rs. 25,06,517, against this the maintenance charges, direct and indirect, and including the charges for collection, amounted to Rs. 14,58,228. The net revenue, calculated on the earnings of the

year was therefore Rs. 14,07,950. It would, however, appear from paragraph 12 of the Superintending Engineer's report, and from paragraph 4 of the Commissioner's memorandum, that some claims or remission were still unsettled at the close of the year, and that deductions from the canal share of the consolidated revenue to the amount of about Rs. 90,000, will have to be made in the accounts for 1884-85.

The Poona Horse Show will be opened on Wednesday, 7th October, and will remain open the following day. His Excellency the Governor has given his patronage to the Exhibition. H. E. the Commander-in-Chief is vice-patron, there is an influential list of stewards, and Major S. Babington is joint secretary. The Collector of Poona, who will be glad to receive subscriptions to the prize fund, acts *ex-officio* in a similar capacity. To the fancy classes Rs. 500 has been allotted as prize money, but this is conditional on the public subscriptions being made on a sufficiently liberal scale, otherwise a proportionate deduction will be made from the awards. No entrance fee is charged in the *bona fide* breeders' classes, and exhibitors are treated very liberally, Rs. 4,335 being divided as prizes throughout the various classes in this department. This sum is provided by the Government grant-in-aid and by special contributions from the public towards the improvement of country-breeds. The conditions have been carefully framed, and discretion is given to the joint secretaries to pay batta to exhibitors, to grant free railway passes for animals, and to remit entrance fees in the cases of poor exhibitors. Concessions for the carriage of horses to and from the show have been obtained from the G. I. P. and B. & C. L. Railway Companies.

Selections.

REPORT ON EXPERIMENTS AT ALON.

From E. Romanis, Esq., Chemical Examiner, British Burma,* to the Director of Agriculture, British Burma,—dated the 20th May 1885.

I HAVE the honour to forward herewith my report on the Alon farm. It is much shorter than last year's, as there is only six months' work to be recorded.

It has been delayed by my absence examining minerals in Tenasserim.

The agricultural experiments at Alon were discontinued at the end of January, but resumed in September 1884. It was then too late to attempt anything with sugarcane, but rice-planting was still going on, and seven plots were planted with rice purchased from natives. Of these, two were unmanured as in 1883; one received twice the quantity of nitre it did the previous year.

The plot manured with bone-dust in 1883 was divided; one-half received bone dust at the rate of 10 cwt. per acre, the other had no addition.

The plot manured in 1883 with dissolved bones was similarly divided; one-half was left, the other had night-conservancy carts emptied on it at the rate of 120 per acre.

There was a drought in October, which appeared to injure those plots most which were a little higher than the others. The effect of a slight difference of level was very obvious. This cause of error must be eliminated by making plots of the same manure at each level and taking the average.

The dissolved bone plot gave the best result; the addition of the conservancy manure made no difference. The two plots with ground bones came next, but the extra supply did not produce a proportionate increase in the crop.

The nitrate of potash this year gave a lower result than the unmanured, whilst last year it was almost equal to the dissolved bones. Probably the soil was exhausted by last year's crop. The unmanured gave practically the same result as last year. The results are tabulated below:—

	1884.		1883.*	
	Grain.	Straw.	Grain.	Straw.
Ia.—Dissolved bones (laid on in 1883) ...	2,420	2,415	2,165	2,785
Ib.—Dissolved bones plus conservancy manure ...	2,420	2,500
IIa.—Bone-dust, 5 cwt. in 1883 ...	1,916	2,342	2,291	2,969
IIb.—Bone-dust, 5 cwt. in 1883 and 10 cwt. in 1884 ...	2,136	1,960
III.—Nitrate of potash, 110lbs. in 1883 plus 220lbs. in 1884 ...	1,149	1,124	2,040	2,160
IV.—Unmanured ...	1,392	1,653	2,055	2,535
V.—Unmanured ...	1,282	1,930	1,300	1,665

* I must here state that the column headed "straw" in last year's report on the Alon farm, paragraph 44, should read "straw and grain," and the column headed "total" deleted.

It will be seen that there has been a decrease in every plot but in final 1b, where there is an increase of 250lbs. per acre. The conservancy manure was put on B, but it is most likely that it was washed over into A by the overflow of the water.

I intend this year to try the effect of lime on the soil.

II.—SUGARCANE.

There were six plots planted with sugarcane in December 1884. The manures were bone-dust and nitrate of potash, bone-dust and chloride of potassium, dissolved bones and chloride of potassium, dissolved bones and nitrate of potash, and dissolved bone and nitrate of potash after lime. The last so far looks the best. The chloride of potassium, proposed as a cheap substitute for nitrate, appears injurious, probably because of the common salt which it contains.

JUTE.

The jute planted in 1883 at Alon failed because of the wetness of the soil. In 1884 the experiment was repeated in a drier situation. The manures used were nitrate of soda and nitrate of potash. There was no difference in the result. The jute attained a height of 5 to 6 feet, when it flowered; very little of it was fit for making fibre. I infer from the experiment that the soil is deficient in lime.

SORGHUM.

After the jute was cut, the ground was prepared for sorghum. There were five plots,—two unmanured, one had nitrate of potash alone, one dissolved bones alone, and the last a mixture of nitrate of potash and dissolved bones.

The proportions were—

I.—Unmanured.	...	195	} lbs. per acre.
II.—Nitrate of potash	...	1,325	
III.—Dissolved bones	...	1,325	
IV.—{ Dissolved bones Nitrate of potash	...	105	
V.—Unmanured.	

I could get no information as to the best time for sowing. Sorghum is said to ripen in four months, and to require cold weather to produce the largest quantity of sugar. I, therefore, planted in October. I am now inclined to think that the middle of August would be a better time.

I had canes cut from time to time, the juice expressed, and the sugar determined by the optical method. The results are somewhat irregular, as the growth of the canes was unequal, but on the whole they appear to show that the maximum of sugar was about the end of December.

CRYSTALLIZABLE SUGAR.

	26th November.	27th November.	6th December.	10th December.	10th December.	16th December.
I.—Unmanured	8.20	...
II.—Nitre
III.—Dissolved bones	...	2.0	...	9.62
IV.—Dissolved bones and nitre.	5.16	...	4.50	...	Yellow 6.62	Purple 14.2
V.—Unmanured

	9th January.	9th January.	10th January.	12th January.	12th January.	14th January.	14th January.
I.—Unmanured	5.40
II.—Nitre	7.29
III.—Dissolved bones	8.65	10.33	...
IV.—Dissolved bones and nitre.	...	12.30	8.62	7.98	11.18α
V.—Unmanured

(α) Taken from the mixed juice of the whole plot.

Nos. III and IV were nearly equal, No. IV slightly the better. The canes were from six to eight feet high; on No. II they were from three to five feet; on Nos. I and V the crop utterly failed.

The juice contained about 17 per cent of solid matter, of which only half was crystallizable sugar. As the other solids prevent the crystallization of cane sugar, the juice when evaporated gave a dark treacle of a bitter taste.

I do not think that sorghum is suited to Burmah. It is not so rich in sugar as sugarcane, and the manufacture of sugar from it requires far more skill. It is true that it occupies the ground for only four months, but it is the same time as rice, and there appears to be no advantage in replacing rice by sorghum. The cultivation of sorghum in the United States is the result of protective duties. There it has taken the place of maple sugar. But under natural conditions, I do not think it could compete with sugarcane. It seems unnecessary to make any further experiments with sorghum.

EXPENSES AND RECEIPTS.

The farm has been enclosed with a wire fence, and a well for irrigation dug, at a total cost of Rs. 1,200. The working expenses were Rs. 292-11-0. The rice sold for Rs. 27-8-0. The sugarcane cannot be cut until November.

NITROGENOUS MANURES.

By DR. A. P. AITKEN,

Chemist to the Highland and Agricultural Society.

THE most powerful and by far the most important nitrogenous manures are nitrate of soda and sulphate of ammonia. The former is found as a natural incrustation of the soil in Chili, Peru, and Bolivia, and forms a great source of wealth to these countries. It is purified and exported in enormous quantities to Europe and other countries. The exports have for some years averaged about half-a-million tons per annum, and about one-fifth part of it has been imported into Great Britain. Sulphate of ammonia, which has for many years been saved as a by-product in the manufacture of coal gas, is now being saved in other industries which have for years allowed it to go to waste. Paraffin oil works have been recently supplying the markets with it, and it is probable that in a few years the supply from that source, and from steel works and other industries where coal and shale are being distilled, will become so great as to render us comparatively independent of the foreign supply of nitrate of soda.

These two substances are supplied to farmers in a remarkably pure state. It is seldom that the impurity, or the *refraction* as it is called, exceeds 5 per cent. They are valuable as manures on account of their nitrogen, and the amount of nitrogen they contain is usually expressed in its equivalent of ammonia; or, in other words, these substances are valued according to the amount of ammonia they are able to yield. Roughly speaking, good nitrate of soda can yield one-fifth of its weight of ammonia, and good sulphate of ammonia yields one-fourth of its weight of ammonia. The latter is, therefore, the more concentrated form of nitrogenous manure, for 4 cwt. of it are equal to 5 cwt. of nitrate of soda.

In making use of these substances as manure, we have to consider other circumstances besides their concentration. We have to consider their relative activity, that is to say, the rapidity with which the roots of a crop are able to absorb them. It is a matter of common experience that nitrate of soda is the more rapidly-acting form of manure, so that its want of concentration is compensated by its activity. The cause of this greater activity has during the last few years been investigated by various chemists with remarkable success. It has been found that sulphate of ammonia and other ammonia salts are converted into nitrates in the soil by means of a minute living organism, which has been called the nitrifying germ, or ferment. This organism has already been referred to as existing in all fertile soils, and as capable of converting the nitrogen of various kinds of nitrogenous matter into nitric acid, which, combining with lime or some other salifiable base, forms nitrates for the nourishment of plants. When nitrate of soda is supplied to the soil it is already in a form in which the roots of plants are able to absorb it; but when sulphate of ammonia is applied, it has to be converted into a nitrate by means of the nitrifying germ before it is in a form suitable for absorption by the roots of plants. The speed with which this conversion goes on depends on the abundance and activity of the nitrifying germs, and that has been shown by Mr. Warrington, of Rothamsted, to depend on various conditions, such as warmth, aeration, and the presence of lime or other suitable base.

The relative activity of these two forms of manure determines to some extent the use to which they are to be applied. When an immediate increase of growth is wanted, the nitrate is the better

manure, but in order to attain that result the roots of the crops must be there to absorb it. Both of these salts are very soluble but the nitrate is the more soluble of the two, and it is the one which is least able to be retained by the soil; so that if the roots are not already well established, there is certain to be a loss of nitrate, especially during wet weather, for it passes down through the soil and into the drains, unless the roots of plants are there to retain it and carry it up to assist in the growth of the crop. It is evident, therefore, that the best way to apply nitrate is as a top-dressing on a young crop whose roots are established, and that the crop which is able to make the best use of nitrate is one whose roots are most abundant. It is on this account that even a slight dressing of nitrate produces so marked an effect upon a *gîte* crop; and, on the other hand, it is to this peculiarity of nitrate of soda that we must ascribe the failure which frequently attends its application to the root crop fallow, especially during wet seasons. During a dry season nitrate of soda is a most efficacious manure, and when applied along with the seed of the turnip crop may have the effect of saving the crop by accelerating the growth and carrying it beyond the reach of the turnip fly, and in such seasons its use is to be recommended for such a purpose; but unless some other more slowly-acting kind of nitrogenous manure is applied along with it, there will be a deficiency of growth during the latter part of the season. For the benefit of the crop, as the season advances, sulphate of ammonia is the preferable form of manure, and it is to be preferred on other grounds as a component of a turnip manure. Where dissolved phosphates—and especially superphosphates—are used as the basis of a manure for a root crop, sulphate of ammonia may be mixed with it, but not nitrate of soda, for it is decomposed by the acid present in the mixture, and the products formed may be productive of injury instead of benefit to the crop.

Generally speaking, the relative utility of these two powerful nitrogenous manures may be described thus—sulphate of ammonia may form a most effective part of a mixture which is applied with the seed, while nitrate of soda is most efficaciously and economically applied as a top dressing. Sulphate of ammonia may also be applied with good effect as a top dressing to root crops, but when so applied to cereals it has the effect of prolonging the growth during the latter part of the season, and thus retarding the time of ripening. Both have a very marked effect on the growth of cereals, but they tend to increase the straw more than the grain. Applied to grass or pasture, they greatly increase the leaf, and encourage the growth of true grasses, but diminish the amount of clover. Ammonia salts, especially when applied to meadow in large quantity, as shown by the Rothamsted experiments, exterminate clover and leguminous plants. Nitrate of soda does so to a less extent, and upon the whole it has a more beneficial action as a manure than sulphate of ammonia, not only on the crop, but also on the texture of the soil, and especially of the sub-soil.

These manures are sometimes called *stimulants*, but that is not a correct name to apply to them. The word *stimulant* is properly used to describe a substance which produces a growth to which it does not substantially contribute, but that cannot be said of nitrate of soda and sulphate of ammonia, both of which contain an essential element of plant food. When used alone they exhaust the land more rapidly than when no manure is applied, for nitrogen is the manurial substance which is usually most needed in soils, and, by applying it, the soil is caused to yield up its mineral constituents more rapidly. When their inordinate use is persevered in, the crop rapidly diminishes to an unprofitable limit, involving a double mischief—the impoverishment of the tenant, and also of the land. On that account these substances should either be used on land in good condition, or an adequate amount of phosphatic and potassic manures should be applied along with them.—*North British Agriculturist*.

NOTES ON ECONOMIC PLANTS.

[Report on the Royal Botanic Gardens, Ceylon, 1884.]

Cinchona.—The year has been characterized especially by an immense export of bark—more than ten million (10,139,933) lbs. This, which is considerably more than three millions over that of the previous year, is in excess of all anticipations. As a result the price of Quinine has continuously fallen to its present price of 4s. to 4s. 6d. per cwt., and of bark to 5½d. or 6d. per unit of Quinine. Yet the value of the bark exported in the year 1883-84 is estimated at over 4½ million rupees—more than three times that of the tea exported in the same period, and the cultivation

In Ceylon is still very remunerative to the growers of good barks. The fall in value has, on the other hand, been disastrous to the South American bark trade, and the export from that part of the world has been greatly reduced. The lowering of the price of Quinine must be regarded as a great benefit to humanity, and is indeed the very object which the originators of cinchona cultivation in the East set before themselves.

A little more seed of "Caprea Bark" (*Rimjia*, sp.) was received from Kew in July. Mr. Ngok reports that all failed to germinate except about 200, which were sown in a pan placed in rather strong bottom heat. Of these, unfortunately nearly all were eaten off in one night, and at the close of the year only two or three tiny unhealthy plants remained.

A good series of cinchona barks was exhibited by the Planters' Association at the Calcutta Exhibition. At the request of Mr. Copper, the Commissioner, I drew up for his "Handbook to the Ceylon Court" a succinct account of the history and position of cinchona cultivation in Ceylon.

By the courtesy of Mr. J. V. H. Owen, I have had the opportunity of examining his plantation of "Verde" and "Morada" cinchonae in new Maturata. The oldest of these trees are now 2½ years, and commencing to flower. They present a considerable range of variety, though less than when seedlings, and generally maintain their robust character. The large proportion belong to a type which is distinct from any I have seen here hitherto. It is, however, I consider, a variety of *O. Oulsiaya* and not of *O. Ledgeriana*, and is best characterized by the foliage. The remarkably intense coppery or vinous colouring of the under-surface of the leaves, so striking in the young plants, usually disappears gradually in the older ones, but it is as conspicuous as ever in young shoots sent up from their base. The leaves of the flowering trees are remarkably broad for *Oulsiaya*, rather obtusely pointed, quite smooth, firm, and with very large acrobiculae. The flowers vary greatly in size and colour as in other *Oulsiaya* forms. No analysis of the bark has as yet been made; the varieties of *O. Oulsiaya* hitherto grown in Southern India and Ceylon have not proved satisfactory as Quinine bearers, it remains to be seen if this will be an exception.—[Note added, March, 1885.]

Cacao.—The growing importance of this cultivation to the colony is seen by the large increase in its export, 9,863 cwt. in 1883-4 against 3,538 cwt. the year before. The position is very encouraging on the whole.

The varieties received in 1881 from Trinidad having now for the most part fruited, I have been able to look into the characters and differences they present. The whole of them produce seeds which are more or less dark violet-coloured on section when fully ripe, and thus differ completely from the variety in general cultivation here, which has the seeds pale yellow within. As regards the names under which they were received, and which have been very carefully kept attached to the plants from the beginning, they do not appear to connote any very constant or distinct characteristics or differences, so far as these examples allow me to judge.

The names of the strains, as sent by Mr. Prestoe with the plants, were as follows:—

<i>Forastero</i> (numbered 8 & 13),	<i>Verdilio</i> (numbered 12),
<i>Cundeamar</i> (numbered 10, 14, 15),	<i>Sangre Toro</i> (numbered 5),
<i>Oapenne</i> (numbered 15 & 16),	<i>Oriollo</i> or <i>Oakro</i> (numbered 9 & 17),

and, in addition, a number labelled "Forastero, several best selected varieties mixed." Most of these might apparently come under some of the other names, and indicate that the name "Forastero" is used also in an extended sense to include them.

The variety in shape, size, and colour of pod, and number, weight, and form of seed is remarkable; and as I have had careful coloured drawings made of each sort as they ripened, they can be readily compared with one another and with descriptions. Among them are some undoubtedly very fine sorts; and some others as characteristically bad, with small round pods, with very thick walls and few seeds. The worst I shall destroy, lest they should injuriously affect the others by cross-fertilization.

Forastero (No. 8), *Sangre Toro* (No. 5), and *Oriollo* (No. 9), have not yet produced ripe pods, but of the remainder the most desirable sort as judged of by number, weight, and character of seeds appears to be the *Cundeamar* (No. 10). The pods of this variety, of which we have six trees, have all been deep-red, usually somewhat pointed, with the 10 grooves rather deeply marked, and, as the name indicates, the kind somewhat nodular or worted; the seeds are long and almond-like and show on section a broad oval, that is, they are but slightly compressed. Among the other *Cundeamars* (Nos. 14 and 16), is a considerable range of variety, some are yellow-podded, and of these one tree of No. 16 appears to be a specially fine sort.

I had looked forward to the fruiting of the *Oriollo* variety, expecting it to exhibit characteristic differences from all the other kinds. The two trees of No. 17 have, however, produced pods and seed which it would not be possible to distinguish from some of the *Cundeamars*. The *Cacao* properly called *Oriollo* (or *Creole*) is said to be distinguishable by its smaller pods (which are red), and especially by its almost globular seeds, the interior of which is a "pale crimson," and which have a particularly fine flavour. The plants sent here under the name do not exhibit these peculiarities. This was formerly the only kind grown in Trinidad (hence "Oriollo"—native), but was destroyed there; and is now principally cultivated in Venezuela, where it affords the well-known Caracas *Cacao* of commerce. In Trinidad its place has been taken by the *Forastero* (=foreign) varieties. As to which of these two classes the old "Ceylon" *Cacao* is to be referred; if to either of them, I am unable to say. It is believed to have been received about 50 years ago from Trinidad,* and may have become somewhat modified since its introduction.

I have made a small distribution of the pods and young plants of the varieties of these Trinidad *Cacaos* to such planters as were desirous of trying them, about 30 in number. The small number of the trees of course rendered anything more extensive impossible at present.

The endeavour to spread *Cacao* cultivation among the villagers in suitable districts has been carried on, and during the year, 3,500 pods (about 10,500 seeds) and 1,100 young plants have been sent out from Heneratgoda for distribution by the Government Agents through the headmen. I drew up in May some simple instructions for cultivation, which were printed in the vernacular as well as in English, and given out with the plants and seeds.

In my last Report, I called attention to the damage done on a few estates to the young shoots of *Cacao* by the punctures of a sucking bug, *Helopeltis Antonii*, and expressed the hope that it would not spread widely. At the time I was not aware that this insect was a native of the island as seems to be the case,† but I am glad to be able to report that it does not appear to be generally distributed here, and shows a tendency to restrict itself to particular localities. In a few neighbouring places towards the end of June (after a long drought), the condition of the *Cacao* was so serious that I was requested to visit and report officially on the cause. This I did and satisfied myself that, as had been suspected by me, this insect was the principal source of the injury. In a report submitted in September,‡ I was able to some extent to trace out the life-history of *Helopeltis*, and the nature of the damage done both to the shoots and the young pods. The eggs are, without doubt, laid in the young succulent shoots; whether also in the young pods is not certainly determined; in all stages the insect is active, and lives by sucking the tender young tissues of the plant. I recommended systematic catching and destruction of the larvae and perfect insects as the best method of dealing with the pest, and where this was thoroughly carried out the good effects were quite evident. The insect is not, as compared with some pests, very abundant, but over 2,000 a day were being caught on one estate during the wet weather of October, when the *Cacao* was shooting up vigorously and a single bug commits much damage. The effects of the drain on the fluids of the trees are much more serious where *Cacao* is also exposed to the drying effects of sun and wind.

India-Rubber Ceara.—I have nothing further of a practical nature to report as to any method of collecting the Ceara-rubber at a cost sufficiently low to make it profitable to the European planter. It is, however, clear, that as the trees attain a larger size and greater age, there is a more copious flow of milk, and the tears of rubber obtained by leaving it to dry on the trees are larger and more solid. One of the original trees in Pera leniya, nearly 8 years old and about 14 inches in diameter has lately been cut down in making a new path; this tree had been thoroughly drained of milk in 1882, but on now repeating the operation, nearly 1½ lb. of dry rubber was obtained.

A considerable distribution of seed (10,300) has been made to the Government Agents for experimental native cultivation. The tree will bear a dry climate and does well at Anuradhapura.

* *Cacao* was grown in the Botanic Garden (then at Kalut ra) in 1819, and may have been introduced by Moon, the Superintendent. But the origin of most of the present cultivated *cacao* seems to have been a consignment from Trinidad obtained by Sir R. Horton in 1834-5.

† In the original description of the insect by Dr. Signoret published at the end of 1883, the locality given is simply "Ceylon." The author received the specimens from Dr. Anton Dohrn to whom he dedicated the species.

‡ Printed in the *Tropical Agriculturist* for October, 1884, Vol. IV, pp. 327-329.

Castilloa Rubber.—On application from the Superintendent of the Model farm at Kalutara I supplied 300 large seedling plants to that institution, and I am glad to learn that they are growing well, and have proved vigorous young plants.

The Government of Madras being desirous of continuing the experimental culture of this at Nilambur, a further consignment of 3 Ward cases containing 190 young plants was sent to Messrs. Hinde & Co. in March and July.

The measurement of the largest tree, 43 feet high, of the species at Heneratgoda is 32½ inches in circumference at a yard from the ground.

Para Rubber.—A good crop of seeds was produced at Heneratgoda, and over 1,000 seedlings were raised; most of these were distributed to officials in suitable parts of the colony. A few seeds were also produced for the first time at Peradeniya in August.

In March, a case of 28 plants was sent to Calicut for the Madras Government. A box of seeds sent in July appears to have not reached its destination.

Our largest tree of *Hevea brasiliensis* is now 63 feet high and 36 inches in circumference at a yard from the ground.

Hevea Spruceana has not succeeded so well as its more important congener. The only two plants remaining at Heneratgoda are not in good health.

Other Rubber-yielding Species.—*Tabernaemontana crassa* has grown up to 8½ feet high with very handsome leaves 15 by 9½ inches; a striking plant of *Landolphia Kirkii* is in flower all through the year, but has produced no fruit; its main stem is nearly 6 inches in circumference. *Uroala esculenta* from Burmah (see Report for 1882, p. 13) has become an unmanageable climber of large size, growing rapidly and spreading widely. The leaves on the older branches are now quite smooth; it flowers very freely, and has formed abundance of ripe fruit. It is difficult to understand how these can be edible as is said to be the case.

Nine plants of the "Talaing Milk Creeper," of Burmah, have been received from Col. Seaton, of the Indian Forest Department, and a few more from the Calcutta Botanic Gardens. This is *Parameria glandulifera*, another apocynaceous rubber-yielding vine. Attention was first called to it by Dr. Pierre, late Director of the Sargol Botanic Garden. He introduced it from the forest into that garden in 1874, but it grows throughout the Malay Peninsula.* The rubber which is said to be of very superior quality is prepared by heating with water. The plant is found from sea-level up to 3,000 feet; like other rubber-yielding climbers of this family, large forest trees are necessary to afford it a proper opportunity for growth, and thus they are all unsuitable for ordinary estate cultivation, but would be valuable as forest products.

Gutta Percha.—The young trees of *Gutta Taban Putih* continue their natural slow growth, the largest (at Peradeniya) is now 2 feet 10 inches high. From the dried specimens sent by Mr. Wray from Perak, I was not able to determine this species of *Dichopsis*; but Mr. Thibault Dyer now informs me that it is, he believes, identical with *Palaquium* (= *Dichopsis pustulatum*), Pierre. The determinations of the other Perak species of "Gutta" given in my Report for last year (p. 14) are further corroborated by Mr. Dyer, who has been carefully examining the series of Mr. Wray's plants sent to Kew.

Gutta Sundek (Paysona Leerii) has made good growth this year, some of the young trees being now 12 feet high.

I am indebted to Kew for plants of the tree affording the peculiar variety of Gutta Percha known as Gum Palata. This is *Mimusops globosa*, a native of Guiana, Trinidad, and some of the West Indian islands. It is a large tree occurring under two forms (species), and its product appears likely to become of increasing use in various ways.

Erythroxylon Coca.—At the close of the year, a renewal of interest in "Coca," the well-known masticatory of Peru and Bolivia, has been caused by the discovery of a valuable property in the alkaloid contained in the leaves. Cocaine is now found to be a very effective and manageable local anesthetic, and thus of great use in operations on the eye, throat, &c. Hence has sprung up a considerable demand for it in Europe and enquiries as to the plant and its suitability for culture in Ceylon. *E. Coca* has been grown in the Gardens for several years having been introduced through Kew in 1870. Growing as it does here in a hot climate and mostly in shade, it forms straggling bushes reaching 12 feet or more in height with long weak branches. Cultivated in the open and subjected to periodical plucking of its leaves, it would doubtless soon put on a much more compact habit. It blossoms profusely several times a year, the multitudes of small yellow faintly-scented flowers completely covering the long branches; but not much seed is produced, most of the flowers falling to set. The fruit is scarlet, small, and one seeded; the plant can be also readily grown from cuttings. The Coca grows well at Heneratgoda, but at Hakgala an attempt made two years ago did not prove successful; a new trial is being made there: as the plant is in South America cultivated up to 5,000 feet or higher, it may be expected to grow well in our hill districts up to at least that elevation.

In the preparation of the leaf all that is needed is gradual but thorough drying, and the careful avoidance of any dampness or incipient fermentation. When finished, the leaves should be flat, thin, and brittle, and of a uniform pale yellowish-green.

I may add that we have in Ceylon a closely allied species, *M. monogynum*, which is common in the hot dry districts, and called in Tamil "Tevadaram." The wood is slightly fragrant, and Dr. Ondaatje has recorded the preparation from it of Puttalin of a crescentic oil. The leaves are strikingly like those of *E. Coca*, and it is interesting to note that in South India, they were

largely used as food by the poor during one of the late famines, as recorded by Dr. Bidie. They may possibly contain Cocaine.

Nux Vomica.—The export of these seeds from Indian ports, especially from Madras, has long been an important one, but I am not aware that any are sent from Ceylon. Yet *Strychnos Nux Vomica*, the "Goda kaduru" of the Sinhalese, is a common enough little tree in the drier parts of the Island. The seeds are the principal source of the very poisonous but valuable toxic alkaloids, strychnine and brucine. The publication of an interesting paper by Messrs. Dunstan and Short in the *Pharmaceutical Journal* (reprinted in *Tropical Agriculturist*, November, 1884) calls attention to this as a Ceylon product, being based on a series of specimens sent from Hambantota by Dr. Ondaatje, Medical Officer of Galle. The researches of these chemists show that the Ceylon seeds are remarkable for their very high percentage of alkaloids, every specimen examined containing a much greater proportion than the richest known Indian examples. The bright orange fruit contains usually from two to four seeds, (but may have as many as nine), which are of different sizes in the same fruit; these investigations show that the larger the seeds, the greater the percentage of total alkaloids.*

Vegetables from Jamaica.—*Arracacha.*—This umbelliferous plant, *Arracacia esculenta*, a native probably of the Andes of South America, where it is cultivated up to 6,000 feet, was introduced into Jamaica in 1822, and produces large edible starchy roots with the flavour somewhat of parsnip. Two or three attempts to import the roots in a living state have proved completely unsuccessful, but Mr. Nock has now succeeded in raising some young plants from seeds sent from Jamaica, which it is hoped will in time develop the edible portion.

Ocho-ocho (Sesuvium edule).—This is an excellent vegetable much in favour in Tropical America and the West Indies, and also grown in the Mediterranean region under the name of cayote or cayote. The firm, fleshy, irregular fruit contains only a single large seed, and is thus very unlike other gourds. A case of plants of this, received from Kew in October, were all dead on arrival, but I have applied to Jamaica direct for seed,†

Tree, Tomato (Cyphomandra betacea).—This is a close ally of the ordinary tomato, and a native of Peru and neighbouring countries, but cultivated in the hills in many parts of South America and the West Indies. Its fruit which is red and the size of a pigeon's egg may be employed in all ways like the tomato and resembles it in flavour. Seeds have been received from Jamaica, and there are now many young plants at Hakgala.

Socotra Dragon's blood.—The source of this ancient drug and pigment was not known with certainty until Dr. Bayley Balfour's exploration of the Island of Socotra in 1880. He named the species of *Dracena* which yields it, *D. Cinnabari*, Bal.f. A box of young plants of this interesting plant was sent to me from Kew in June. As the wet climate of this part of Ceylon would quickly prove fatal to them, they were sent to Anuradhapura where they will stand a better chance. But little of this ancient Cinnabar or Dragon's blood at present comes into trade (through Bombay), most of the substance now so called being the produce of a rattan of the Malay region (*Calamus Drace*), and shipped from Singapore.

Tropical Fruit-trees.—It is worth mention, as a somewhat unusual event, that one of the Durian trees at Peradeniya gave a heavy crop of fruit last August. The tree is a young one, about 18 years old, and had not flowered before. The very large old tree which flowers so profusely every year also produced a few ripe fruit this year. Several other Malayan fruit trees also bore well, as the Mangosteen, Santol, &c. The "Chinese Quince," *Diospyros Ebenaster*, of the Philippines, also produced abundance of its handsome and sweet scented golden fruit which are however very poor in flavour.

Fifteen grafted mangos of approved varieties were received from the Poona Botanical Gardens and planted at Peradeniya.

There is a good supply of seedling Cherimoyer trees available at Hakgala. The fruit of this tree (*Annona Cherimolia*) is considered to be far superior to the other species of the genus *Annona* (the custard apple, sweet soap, &c.,) but the tree is adapted only to the hill climate of Ceylon.

Eucalyptus Plantation.—The trees are now nearly 2½ years old and grow well and rapidly. Of the 15 kinds selected for measurement last year, *E. Gunnii* is now the highest, 26 feet with a girth of 10 inches; *E. robusta* is 24 feet and 15 inches in girth; *E. marginata* 25 feet and 13 inches in girth; *E. longifolia* 24 feet and 14 inches in girth; these are the quickest in growth, at their present early stage, of the species we have.

Coco-de-mer.—In response to an application made in 1882, I have received from the Chief Civil Commissioner of the Seychelles, through his Excellency the Governor of Mauritius, 10 seeds of this rare and magnificent palm. They arrived in April and were at once planted—7 at Heneratgoda and 3 at Peradeniya. As yet there are no signs of germination, but the usual period occupied in this process is from 18 to 30 months, so that this is not to be expected. Peradeniya already possesses two beautiful specimens of this unique Palm, about 80 years old, but in the case of so extremely local a plant as this, and one of such peculiar interest to naturalists, it is much to be desired that a large stock should be in existence, so that in time it may be possible to propagate by seed from another centre. This palm, being, like the *Palmyra*, dioecious, it is necessary to have sufficient plants to make it probable that both sexes will be represented among them.

* The pulp in which the seeds are immersed contains a small proportion of Strychnine, so small that it is said that this pulp is eaten by birds. Dr. Ondaatje has, however, settled by experiments on dogs, cats, and pigeons that it is totally poisonous in sufficient quantity.

† A box of germinating seeds arrived in January 1885, and one of them has survived. From this there are now three rooted cuttings at Hakgala.

* It has not been found in the Indian Peninsula or in Ceylon.

THE

INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA:—SATURDAY, AUGUST 15, 1885.

[No. 3]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING AUGUST 5, 1885.]

General Remarks.—In the Madras Presidency all districts report rain, but more rain is wanted in Bellary, Ganjam, Coimbatore, and Tanjore. Prospects have improved in Bellary and Anantapore, and are generally fair, except in Madura, where they are unsatisfactory. In Mysore the rainfall was slight and insufficient for the young crops. Fodder is reported to be becoming scarce, and ploughing and sowing operations are retarded in places. In Tumkur and Kolar, prospects are uncertain; and though they are moderately fair elsewhere, the harvest will depend on the future rainfall. In Coorg the season continues favourable.

General rain is reported from the Bombay Presidency, but more is wanted in parts of Karwar, Ahmednugger, Bijapore, Poona, and especially in Sholapore, Khandesh, and Nasik. The condition of the young crops is generally good, though in places they are reported to be slightly injured by blight and insects. Fodder is scarce in some districts. In the Berars, Hyderabad, the Central India and Rajpootana States rain has been general, and the crops promise well.

Little or no rain fell in the Punjab during the week under report. The *khari* sowings have been nearly completed, and prospects are, on the whole, good; but more rain is wanted. In the North-Western Provinces and Oudh good rain continues to fall, but a break would now be beneficial. Prospects are everywhere good. Wet weather continues in the Central Provinces, where a break is now wanted in some districts. *Rabi* sowings have commenced, and weeding and transplanting continue.

Rain has fallen throughout Bengal, and prospects are favourable everywhere. Transplanting is progressing favourably, but more rain would be beneficial in some parts. In Central and Eastern Bengal the *bhadoi* harvest is in progress, with prospects of a good average yield of early rice. Seasonable weather prevails in Assam, and agricultural prospects continue good.

In British Burma ploughing, sowing, and transplanting continue. The public health is generally fair in most provinces.

Prices are generally stationary, except in the Punjab, where they fluctuate with a tendency to rise. In Bengal the price of rice is still high.

Madras.—General prospects fair, improved in Bellary and Anantapore; in Madura reported to be discouraging.

Bombay.—Rain throughout the presidency; more wanted in parts of Karwar, Ahmednugger, Bijapore, Poona, and especially in Sholapore, Khandesh and Nasik. Young crops generally good, but slightly injured by blight and insects in parts of Bijapore, by insects in part of Upper Hind Frontier, and by floods in parts of Kurrachi; fodder scarce in parts of Nasik, Ahmednugger, Sholapore, and Bijapore. Cholera in parts of Malacca, fever and cattle-disease in parts of seven, and small-pox in parts of four districts.

Bengal.—General rain in all districts, and agricultural prospects favourable; transplanting is generally well forward, but in some parts more rain is wanted; *bhadoi* harvest progresses in Central and Eastern Bengal, with prospect of a good average yield of early rice. Price of rice is still high. General health continues fair.

N. W. Provinces and Oudh.—Rain fell generally throughout the provinces; a break would be beneficial. Prospects everywhere good. Prices steady on the whole. Public health good; cases of cholera reported from Gorakhpore, Allahabad, Ballia, and Agra.

Punjab.—Rain in the Delhi, Simla, and Shahpore districts. Slight cholera in the Lahore and Rawal Pindie districts; elsewhere health is generally good. *Khari* sowings nearly completed; prospects on the whole good, but more rain is needed. Prices of food grains fluctuating, with tendency to rise.

Central Provinces.—Weather cloudy and rainy; break wanted in some districts. Weeding and transplanting continue; *rabi* sowings commencing. Cholera continues in Raipore and Jubbulpore. Prices steady.

British Burma.—Cholera severe in one district, slight in five districts; small-pox slight in one district, elsewhere public health good; cattle-disease severe in two and slight in three districts, elsewhere health of cattle good. Ploughing, transplanting, and sowing progressing. Rains continued and heavy during the month of July.

Assam.—Weather hot; more rain wanted. Public health fair, though fever prevails in parts; prospects of all crops good.

Mysore and Coorg.—Rain insufficient for the young crops, which are suffering in consequence; fodder getting scarce; ploughing and sowing operations retarded in parts; prospects moderately fair, but dependant on future rainfall. Cholera prevalent in parts of Bangalore and Mysore district; small-pox in Tumkur and cattle-disease in parts of Mysore; public health otherwise fair. Prices show slight upward tendency.

Berar and Hyderabad.—*Rabi* sowings continue; *khari* crops prospering. Cholera prevails in the city and suburbs; general health in talukas fair.

Central India States.—Health and prospects good. Prices steady.

Rajpootana.—Tanks and wells full. Crop prospects excellent. Health good. Prices falling.

Nepal.—Weather seasonable. Cholera decreasing in Khatmandu, worse in other places. Prospects fair.

Letters to the Editor.

ENGLISH PLOUGHING vs. DEEP HOEING.

TO THE EDITOR.

SIR,—I have found persons, not sufficiently acquainted with Indian agriculture, advocating deep ploughing and the use of English ploughs. They seem not to know that there is such an instrument as the *kodali*, which, when properly handled, stirs the soil deeper than the Marquis de Trecedale's subsoil ploughs. And so long as the holdings are small, there is not the slightest chance of the English plough displacing the antiquated native *kodali*. In some places this *kodali* may not be so used; and the English plough may come into vogue there. As to the *tangal*, which may be translated into English as a single-tynd grubber, it will always hold its superiority for light ploughing. In Bengal, Behar, and Orissa, paddy cultivation is the most important of all cultivations; he must be a bold man to assert that it will be economical for English ploughs to displace the native *tangals* for paddy cultivation. A light grubber, something like Howard's three-tynd *Indian* cultivator, has a greater chance of success. But it is far too costly. A *tangal* costs about 12 annas, and a three-tynd cultivator should not cost more than two rupees. In agriculture, as in any other business, some succeed while others fail. They use the same *tangal*, *bindtor*, &c. The explanation is to be sought, not in the imperfection of the cultivating implements, but somewhere else. Should gentlemen with capital ever engage in agriculture, the agricultural condition must be changed. To a ryot it does not matter whether it takes him two days instead of one to plough a certain field. But to a person employing hired labour, it makes a serious difference. For a field of half an acre of sugar-cane, can an English plough beat a *kodali*? But if the field be 10 acres, it will be a saving of labour to use the imported article. But I have not seen the Bengali ryot or ryots who own a single field of 10 acres. If you have large fields and hired labour, you may use implements which are suited to such a condition. But the idea of using, in small farming, implements which are suitable for large farming, is simply absurd.

S. DATTA,
Settlement Officer, Moharbhunj.

PRACTICAL EDUCATION FOR AGRICULTURAL SCHOLARS.

TO THE EDITOR.

SIR,—I beg to suggest that the period of education of the agricultural scholars should be extended to three years, and this additional year should be spent in Italy, Germany, or the United States, to study sericulture, the manufacture of tobacco and

sugar, or the cultivation of cotton. Wheat, barley and oats, the cultivation of which is to be seen in England, are not much known in Bengal. Potato cultivation, as carried on by the despised ryots in the neighbourhood of Calcutta and on the Khasia and Garrow hills, cannot be improved upon. There is nothing of paddy cultivation to be learnt in England. So far as cultivation of crops goes, the education of agricultural scholars is more or less theoretical. If a student were to learn the manufacture of tobacco or sugar, as carried on in the States or Jamaica, or sericulture as carried on in Italy, or cotton cultivation in the Southern States, he would bring back to India information which would be really useful to him in guiding others. No amount of education in the Agricultural College can dispense with the acquirement of the elementary lessons in the manufacture of tea, tobacco, sugar, and silk. Next to paddy and cotton, these products hold the foremost place in India. It is, I think, a mistake to exclude a course of teaching in the manufacture of the articles just named, on the technical ground that manufacture is not agriculture. Just imagine the position of the manager of a tea garden who knew nothing about the manufacture of tea! Yet this is the position of our agricultural instructors. They attempt to teach us how to manufacture tea, tobacco and sugar, although they know very little about the matter practically.

S. DATTA,
Mohurbhanj.

Editorial Notes.

The returns for June show a considerable falling off in the opium revenue. The total actual revenue, however, up to the end of June, was Rs. 2,03,45,600, or Rs. 6,900 better than the estimate. This is including the Bengal returns, which are upwards of three lakhs short of the estimate.

From the latest Mauritius papers we learn that not only will the sugar crop this season prove a short one, but that the outturn will be inferior to that of the last crop. This is said to be partly due to the long drought which was experienced at the beginning of the year, and now the cool season has commenced, and has checked the growth of the canes.

We learn that a telegram has been received from Captain Plummer, Manager of the Mysore Gold Mining Company, giving the returns of the production of gold for the month of June, as follows:—"79 tons of rich quartz from the bottom of the mine produced 305 ounces of gold; 3 tons of quartz from the 173-foot level, 6 ounces; and 37 tons of blanket sands from previous stampings, 12 ounces: total, 119 tons yielded 313 ounces of gold."

Kutlow's gives the following figures of the trade of Italy:—The trade of Italy has amounted as follows, during the first four months of 1885, in francs:—Value of goods imported, 506,732,100 (compared with 1884, an increase, 53,320,770); value of goods exported, 330,786,800 (—57,057,100); gold exports 76,718,800 (+73,259,200); gold imports, 2,554,400 (—3,965,000); silver, exports, 30,338,400 (+29,513,800); silver imports, 17,525,200 (+11,627,800).

We are informed that a Conservator of Forests in the Western Provinces considers it desirable to introduce the three varieties of the American tree, known botanically as *Prosopis pubescens*, *duplex*, and *glandulosa* more extensively into the fuel plantations in the dry districts. We can state from experience that these trees grow best on dry, arid soil. They yield a hard, valuable timber. The trees are valuable in other respects as well; they bear abundantly a kind of sweet, succulent pod, which is largely used for cattle feeding. It is also ground into meal, which is sometimes resorted to as a substitute for flour by the famine-stricken in times of scarcity.

We are informed that, at the suggestion of Mr. D. B. Allen, of the Bengal Agricultural Department, the Maharaja of Doomsraon has consented to grant an area of ten acres of good medium land for the purposes of opening a small farm for

instruction. The area will be divided into duplicate plots, one of which will be cultivated in the ordinary native way. A qualified man from the Cawnpore Farm is to be put in charge, who will cultivate the lands under instructions from Mr. Allen. The Maharaja has further agreed to supply the necessary labour and cattle, and to pay the superintendent a salary of Rs. 60 per mensem, as well as the other necessary charges.

The Government of India in the Revenue and Agricultural Department have notified that information has been received from her Majesty's Secretary of State, to the effect that the Lords of the Treasury have assented to the proposal of the Government of India that the building in which the Colonial and Indian Exhibition of 1886 is to be held, shall be treated as a bonded warehouse. This concession has been made on condition that all packages coming from foreign countries, in which term India is apparently included, shall bear special labels, specimen copies of which are to be submitted to her Majesty's Customs. Arrangements have accordingly been made for the preparation in London of the necessary labels of which a supply will be sent to all Exhibition officers as soon as they are received.

In another column will be found a letter from our esteemed correspondent, Mr. S. Datta, the Settlement Officer of Mohurbhanj, on "Practical Education for Agricultural Scholars." We quite agree in the views expressed by Mr. Datta, that it is of primary importance for our agricultural teachers to know something of the manufacture of such products as tea, sugar, and tobacco. We are aware that some of our agricultural officers have given their attention to this subject; and from the official reports occasionally furnished to us, we have seen that Directors and Assistant Directors of Agriculture have devoted some time to the investigation of the various methods of manufacture practised by the natives. Nevertheless, the subject is an important one, and there is much to be learnt. We direct attention to Mr. Datta's letter, particularly to the suggestion regarding the extended period of agricultural education in England, and how it should be utilized.

We learn that the result of the investigation made by Mr. Walker, Commissioner of Lands, British North Borneo, in the gold field on the Segama River, appears to be very favourable. A party which consisted of six men only worked in the bed of the river, and in six days obtained from the scooped-up sand over 3 oz. of the precious metal, the largest find for one day for a single pan being 80 grs. Mr. Walker has ascertained that gold exists in payable quantity in the silt and sand of this river from the 60th to the 200th mile. The success of this exploration has naturally excited considerable interest in the Colony. The Sangei Bilang, a tributary of the Segama, which was formerly supposed to contain considerable quantities of gold in its bed, Mr. Walker has found to be a failure.

TRADE advertising has taken all sorts of shapes and forms, and innumerable are the expedients resorted to for the purpose of bringing wares to the notice of the public. The United States have been foremost in the startling and ingenious character of advertisements, but the Germans have, it appears, gone in for a most extensive business in this direction. It is stated by the *Precurseur* of Antwerp that two commercial associations of Berlin are preparing a travelling exhibition of samples of German manufactured goods. A number of vessels fitted out for the purpose, are to visit the most important ports of Southern Europe and of Africa. Exhibitors will have to pay 322f. per cubic metre, and the voyage will last from eight to twelve months.

BORERS sometimes do incalculable mischief to trees. One of our regular correspondents suggested a method for keeping these pests off, and as there were several of our correspondents anxious to know a remedy, we hope they have been benefited. The following recipe, taken from that practical journal, the *Farmers' Review*, will, we think, prove useful to many of our readers:—"Take a tight barrel and put in four or five gallons of

soft soap, with as much hot water to thin it, then stir in a pint of carbolic acid, and let it stand over night, or longer, to combine. Now add twelve gallons of rain water and stir well; then apply to the base of the trees with a short broom or brush, taking pains to wet the inside of all crevices. It should be applied in the latter part of June in this climate, when the moths and beetles usually appear. The odour is so pungent and lasting, that no eggs will be deposited where it has been applied, and the effect will continue until after the insects have done flying. If the crude acid cannot be obtained, one-third the quantity of the pure will answer, but it is more expensive."

**

The following summary of the London Coffee market is taken from the *Produce Markets Review*:—"A larger supply has been brought forward, but mostly of small, undesirable lots, and several second-hand parcels. The dull tone of the past few weeks has continued, and, except for a few fine parcels, prices are in consequence slightly lower. The public sales have chiefly consisted of East Indian and Central American sorts. For the pale descriptions of the former, quotations are generally in buyers' favour, but all coloury lots have sold well, while really fine bold kinds are slightly dearer. The fine lots of Mysore offered have also fetched higher rates. The advance in this description during the last few weeks has been considerable, but even now prices are much lower than they have been for some years. There is not much change in Plantation Ceylon; fine growths continue scarce and relatively dear. In Costa Rica only a small quantity has been offered, and values are unchanged. Brazil, and other solely export descriptions are in very limited demand, and rather cheaper."

The following tea statistics are furnished by a home contemporary:—"Unlike all other kinds of produce, the stock of tea in the public warehouses in this country is exceptionally low, and the supply of red-leaf China tea threatens to be altogether exhausted before the arrival of any portion of the new crop; yet the price remains stationary. The red leaf is drunk in the south of England, including London, and it is said that no other suits the popular taste. The matter, therefore, is of importance. The stock of this kind at the end of June, 1882, was as much as 50,500,000 lbs.; at the end of last June it was 39,500,000 lbs.; but at the end of the current month it is estimated by Messrs. J. C. Sillar & Co., in the circular just issued, not to exceed 18,000,000 lb. From this the deliveries of July have to be deducted; for the Foochow market has only just opened. The opening is late. At this time last year 5,000,000 lbs. had been exported. Under these circumstances one would naturally expect a marked rise of price; but there is none, and the market is quite inanimate. It must be borne in mind, of course, that in anticipation of an increase in the tea duty, the withdrawals of all kinds of tea from bond were exceptionally large for some time before the Budget statement was made. The stock in warehouses, therefore, does not so accurately represent the available supply in the country, as it usually does. Still the smallness of that stock offers speculators extraordinary facilities for manipulating the market."

**

The prospects of the Bengal Indigo districts are not so good as they were. The heavy rain has checked the growth of the plant, which is small and stunted, and, owing to the lateness of the season, but little improvement can be expected. Owing to the rising of the rivers, some of the concerns have had to cut unripe plant. In Midnapore, the plant has also suffered much from the heavy rains. Manufacture is general everywhere, and the vat produce is fair. The accounts from Bahar vary according to the quantity of rain that has fallen. In some concerns, where the rain has been heavy, the plant is still backward, and the season is fully three weeks later than usual.

In other concerns, which have been favoured with some fine, sunshiny weather, the plant has much improved. It seems doubtful, however, whether the *blounties* will be able to grow to any size this season. Manufacture, except in parts of Chumpanan, has been everywhere commenced; and though the *bigha* produce is bad, the vat produce is fair. The advices from the North-West are very unfavourable, the heavy rain and floods having caused serious damage to the sowings, and the prospects not being nearly so good as they were a fortnight ago.

**

The following figures regarding the debt of India may be of interest:—The total sum of all loans raised in India by the Indian Government, and outstanding on the 31st March last, was Rs. 93,18,36,000, and the yearly interest chargeable on the revenues of the country is Rs. 3,84,12,940, or a fraction below $\frac{1}{2}$ per cent all round. The debt of India raised in England, including debentures and annuities of all denominations, on the abovenamed date, was Rs. 78,15,86,030, and the annual interest thereon Rs. 4,30,72,490. Taken together, the debt of India, in India and England, on the 31st March last stood:—

	Principal.		Yearly Interest.	
	Rs.		Rs.	
England	...	78,15,86,030	...	4,30,72,490
India	...	93,18,36,000	...	3,84,12,940
Grand Total		1,71,34,36,520		8,14,85,430

**

The following is a summary of Messrs. William, James, and Henry Thompson's fortnightly circular of Indian Tea, dated London, Thursday evening, 16th July, 1885:—"There has been a fair business since the 2nd inst., the total sales comprising 10,400 packages, of which 2,600 were old season's; 2,600 second hand, and re-prints, and about 600 from Ceylon. Of New Crop about 4,500 packages have been offered, and these have only sold slowly, though for the good lignoring parcels there has been good competition—but all grades of undesirable quality, though of good appearance, are neglected, and lower quotations have ruled, especially for Broken Teas under 1s., which in some instances show 2d. decline on prices paid for the first arrivals—in leafy kinds the drop ranges from $\frac{1}{2}$ d. to 1 $\frac{1}{2}$ d. per lb. These kinds closely follow the course of the China market, which has been rapidly forced down by frequent sales, 'without reserve.' New Season's Congous with clean liquor selling down to 7 $\frac{1}{2}$ d. per lb. The quality of latest arrivals does not yet show any great improvement, and many of the first invoices from various estates are still coming forward; but judging from musters received by the last two mails, later shipments from some districts should prove of excellent style and liquor. This should help consumption, as with an indifferent crop from China, good Indian Teas must be more freely used to maintain the retailers' standard of quality of previous years."

**

At the instance of Mons. Natalis Rondot, of Lyons, the Chamber of Commerce of that place has decided to undertake a series of studies on the silk-producing worms of every country, on the cocoons of these worms, and on the silk which can be obtained from them, by reeling or spinning. The objects in view are—

(1) To determine, with the greatest possible precision, the general species and varieties of the domesticated, semi-domesticated, or wild worms.

(2) To ascertain the richness in silk of the cocoons, envelopes or silky coverings, the nature and quality of the silk obtained, and in particular the colour, fineness, tenacity, elasticity, yield of raw silk, and the aptitude for taking dyes, &c.

To have all the information possible on the subject, M. Rondot has addressed a letter to the Viceroy, asking his Excellency to help the Lyons Chamber of Commerce in this matter. The Revenue and Agricultural Department of the Government of India have issued a Circular to the several Local Governments and Administrations, requesting them to

distribute copies of the papers to persons interested in the subject, especially to the non-official community. The Government of India do not, however, think it necessary to take up this matter officially for the Chamber of Commerce, but would be glad if the Chamber's enlightened action were brought to the notice of all persons interested in sericulture, and if they were invited to respond to the Chamber's request, as far as they conveniently can.

Mons. Rondot has forwarded, with his covering letter, a circular issued by the President of the Chamber of Commerce of Lyons, which contains two series of questions, with explanatory notes, to be answered by intending helpers in this work. It may be added that the Chamber will be prepared to defray all expenses incurred in this connection by those undertaking his work of enlightenment. Elsewhere will be found the letter from Mons. Rondot, with its annexes.

We suspect that very few owners of cattle in India ever think of changing the food of their stock, or of the consequences that follow by not observing this precaution. The following note, which we take from the *North British Agriculturist*, will, we hope, prove useful in directing attention to this subject.—

"Practical stockmen are generally aware of the importance of judgment and care in changing the food of animals. Such care is especially needful in spring and autumn, when the transition is made from hard, dry food to succulent green stuff, or *vice versa*. Potatoes form a valuable and safe article of diet so soon as animals become used to them; but when first used they require to be given with caution, and also when they are being superseded by other food. In East Lothian and other localities, potatoes, not saleable for human consumption, have this spring and summer been largely consumed by cattle. For this purpose they have been worth about 25s. per ton, or something less than half the price obtained for ordinary qualities disposed of earlier in the season in Edinburgh or other markets. Taking advantage of the drop in the price of stores, some farmers have brought in their cattle. Others have had their courts occupied with dealers' or butchers' beasts, and for two-year-olds have generally received about 8s. per week, furnishing potatoes, linseed cake and straw *ad libitum*. Thriving two-year-olds eat 4 lbs. to 5 lbs. linseed cake, costing at present £8 10s. to £9 per ton. Now that the potatoes are being finished up, it requires, during the transition to clover or vetches, judicious attention to prevent gastro-intestinal disturbance. Alike with horses and cattle, and even when straw, cake, or corn are used, the change from, or to, a potato diet is liable to produce indigestion, tympanitis, and often diarrhoea. It is difficult to explain the cause of such disturbances. The special digestive apparatus, although gradually becoming suited for the effective digestion of food usually presented to them, probably do not digest unwonted articles of diet. To prevent mistakes, keep either feeding or dairy cattle continuously on potatoes should be used in steadily diminishing amount, and their place supplied with grass, cut, and allowed to eat a couple of days. It requires about a week, gradually, to effect this change of diet."

The demand for Burmah cigars has been increasing year by year; and if the proposal recently made by Messrs. H. S. King & Co., of London, to have Indian Tobacco specially represented at the forthcoming Indian and Colonial Exhibition, is successfully carried out, a very material increase may be expected in the demand for these cigars. The note drawn up by Mr. Cabanis, Assistant Director of Agriculture, British Burmah, on cigar-making in that province, has therefore made its appearance most opportunely, and we hope cigar manufacturers will take particular notice of it. Mr. Cabanis personally inspected a number of cigar manufactories in Burmah, and also a large number of cigar makers working at their own houses. What seems to have struck him most was the unnecessary waste of good material, and the wide-spread habit of converting good material into bag. He tells us that the cigar makers generally purchase tobacco of two qualities: the first quality for the wrapper, which frequently costs Rs. 120 per 100 viss, and the second quality for fillers, or the inside of the cigar, at prices

varying from Rs. 60 per 100 viss. If mixed qualities are purchased, at about Rs. 90 per 100 viss, in which case the sorting of leaves has to be done by the makers themselves. It is curious, as Mr. Cabanis tells us, that the smoking, or second quality, is quite as good as the first, the large difference in price being entirely due to the leaf of the latter being larger and more suitable for making wrappers. It is not, however, stated whether the tobacco alluded to is that grown in British Burmah, or that imported from Bengal and Madras. It seems that there is a great deal of waste in cutting the wrappers, though the trimmings from these are often worked in as filling. We are told that a large quantity of the leaf is more or less damaged when made into cigars, by the use of an impure gum or paste for fastening the wrappers. This soon becomes sour, and the cigar becomes mouldy and unsaleable. This is a point which should be particularly noted by cigar manufacturers. Notwithstanding all this waste, the prices charged for the cigars, which are at present up to one rupee per 100, leave a large profit, but Mr. Cabanis thinks that, by the introduction of a more careful system of working, such as that recommended by him, the price could be reduced to eight annas a hundred.

The following summary of American crops is taken from an American contemporary:—"The winter wheat harvest has commenced in the more southern districts. There is nothing in the later reports from the entire winter wheat area to cause us to raise the estimates of the probable outcome of the crop, which were based upon our special wheat report, viz., that at the best the winter wheat crop will not exceed 200 million bushels. Reports of the condition of the spring wheat continue quite favorable, taking into account the entire area. While in some localities its condition is excellent, and in others poor, the average is good, and with a mag. 1. between now and harvest, we shall harvest about 70 million bushels. Other small grains are promising. The corn crop will be one of the largest, if not the largest ever raised in this country. The area in the winter wheat States is greatly enlarged from the ploughing up of ground sown in the preceding years. The outlook for corn at this time is good. The area is unusually large, and though in many districts somewhat late, the stand is fairly good and the plants healthy. Some localities are suffering severely from the ravages in fields of the corn-rod worm, but these are not so extensive as to very materially affect the final outcome of the crop. Other localities have suffered from excessive rainfall, which has kept back work in the spring. Taking the whole country the conditions are fairly good. Taking the country at large, will, we think, be an average crop. Some meadows suffered from the severe freezing of last winter, but the weather since spring opened has been favorable. Pastures continue good, and stock is doing finely upon grass. Potatoes and other root crops are doing well and promise average yields. Small fruits are abundant, but the tree fruits will only make partial crops. This is especially true of peaches which will be almost an entire failure in all northern peach-growing districts. Leaving out the winter wheat, the crop outlook is at this writing, taking the country at large, quite favorable. With the 40 millions of bushels of wheat now in sight, and probably as much more in farmers' hands, we are in no danger of a bread famine even with the short winter wheat crop, and are sure of better prices for what we shall have to spare, than could have been realized if we had grown a full crop this year."

In May last we noticed the revival by the Government of India of some previous orders regarding reports of falls of aerolites. It would seem that this revival has not been without some practical results. Mr. Medlicott, Superintendent of the Geological Survey of India, gives an interesting account of two meteoric falls recently brought to notice, and which are now safely deposited in the Indian Museum. One of these fell at Pirithalla, a village in the Hissar district, at 2 p.m. on the 9th February last. Mr. Medlicott says:—"The stone was received in three pieces, and otherwise damaged, having lost perhaps an eighth of its original bulk. The pieces weighed severally 610g, 425g, 7g."

and 224.2 grammes, or a total of 1,160.5 grammes. The specific gravity is 3.40. The shape was roughly cuboidal with rounded edges and indented sides. The stone is of the most usual type, granular fracture of light-gray colour, mottled pale brown. The numerous metallic grains of various size and shape only appear on a cut surface, being otherwise covered by a coating of the stony substance. This stone is rather friable. There is of course the usual film of fusion, of a dull black colour. The account of the fall received with the specimen is as follows:—The history of the meteorite is briefly this, that it was seen to fall at P. W. on the 10th February 1884, about 120 paces from the village of Pindana, S. Tehana, Hissar Division, by a sepoy and a Sikh, and a boy of 12 years of age. It seems to have been seen when falling, and an explosion was heard while it was still in the air, which was followed by a report like that of a gun when it struck the earth, in which it was buried to the depth of 2½ inches. The ground was hard. It was dug up immediately, and is at present quite cold, and broken in two.

The other meteorite fell at Chanderi, a village near Myapoor in the N. P. provinces, on the evening of the 6th April last. The following is the Mendel's description of it:—"The stone was seen to fall, though about one-fourth of the original bulk, had been mipped off. The shape was roughly cuboidal, with rounded edges and angles. Before cutting, the weight was 1201.3 grammes. The pieces weighed 827.5 and 491.0 grammes. The specific gravity is 3.20. It is exactly of the same type as the Pindana stone, but not so brittle. The following is a German translation of the fall by the Native Sub-Inspector of Police:—

"On 10th April, Gurdas Chanderi, a village near Myapoor, which is about 10 miles from the station, came and reported that four days ago, on the 6th April, there was thunder and lightning, which was very heavy, and after this a stone came down, which was very large and weighed 1200 lbs. and a child named P. W. was killed. A Sikh, a boy, a clerk and a clerk accordingly got the stone. The stone is black, with a white inside, containing shining particles like those of sand. It is broken into two pieces, but it is not so brittle that it will break into small pieces. The clerk who found the stone said, 'The pieces broken off could not be used for anything made by the blacksmith, that on Monday about midnight, about midnight, heavy clouds came over the whole of Chanderi; but Sank Singh Thakur and B. Agga and other Chanderis were busy in stacking, and at that time a field about 100 paces south-east of the village, and they first saw lightning in the clouds and then heard a strong thud; that afterwards it thundered slowly, and then of a sudden the whole sky was lit up and a sound of rattling coming down (sanskrit) was heard, and at the same time the sound of a thud in the arhar field of Madari's. The field beyond their own; that they then ran to their respective houses, fearing that hail was falling. As the affair was one of a surprising kind, they next day morning wanted to find out what it was, and on Sunday found the stone produced in Madari's field; that it was very warm, and the earth below it was blackened, and a part of arhar on which it had fallen, was scorched and broken down, but that no mischief was caused to other plants in the field. Other villagers also testified to these facts. The stone is now for your inspection."

We take the following from the proceedings of the Agricultural Society of India, dated 2nd May 1885, regarding the value of pyrethrum powder as an insecticide:—"Messrs. Beyer & Co. made some enquiries at the suggestion of their Manager, Mr. A. S. Penny, regarding the insect-killing properties of the pyrethrum, and whether any experiments had been made with the plant in India. As there appeared to be some misconception as to the virtues of this plant as an insecticide, the following extracts from the Agricultural Bureau, of Washington, Report for 1883, may prove of interest:—There are very few data at hand concerning the discovery of the insecticide properties of pyrethrum. The powder has been in use for many years

in the Asiatic countries south of the Caucasus Mountains. It was sold at a high price by the inhabitants who successfully kept its nature a secret until the beginning of the century, when an Armenian merchant, Mr. Jurutikoff, learned that the powder was obtained from the dried and pulverized flower-heads of certain species of pyrethrum growing abundantly in the mountain region, of what is now known as the Russian province of Transcaucasia. The son of Mr. Jurutikoff began the manufacture of the article on a large scale in 1838, after which year the pyrethrum industry steadily grew, until to-day the export of the dried flower-heads represents an important item in the revenue of those countries. Still less seems to be known of the discovery and history of the Dalmatian species of pyrethrum (*pyrethrum cinerariofolium*), but it is probable that its history is very similar to that of the Asiatic species. There is also very little information published regarding either the mode of growth, or the cultivation of pyrethrum plants in their native home. As to the Caucasian species, we have reason to believe that they are not cultivated, at least not at the present time, statements to the contrary notwithstanding. As to the Dalmatian plant, it is also said to be cultivated in its native home, but we can get no definite information on this score, owing to the fact that the inhabitants are very unwilling to give any information regarding a plant, the produce of which they want to monopolize. For similar reasons, we have found great difficulty in obtaining even small quantities of the seed of *P. cinerariofolium*, that was not baked or in other ways tampered with to prevent germination. Indeed the people are so jealous of their plant that to send the seed out of the country becomes a serious matter, in which life is risked. The seed of *P. cinerariofolium* is obtained with less difficulty, at least in small quantities, and has even become an article of commerce, several persons here, as well as in Europe, advertising it in their catalogues. In regard to the manufacture of the powder, the flower-heads should be gathered during fine weather, when they are about to open, or at the time when fertilization takes place, as the essential oil that gives the insecticide qualities reaches, at this time, its greatest development. When the blossoming has ceased, the stalks may be cut within about four inches of the ground and utilized, being ground and mixed with the flower heads in a proportion of one-third of their weight. Great care must be taken not to expose the flowers to moisture, or the seed of the sun, or still less to artificial heat."

"We have, during the past three years, largely experimented with it against many species of injurious insects, and fully appreciate its value as a general insecticide, which value has been greatly increased by the discovery that it can be most economically used against the most common insects. No such universal remedy exists, however, as pyrethrum has its disadvantages, as has any other insecticide now in use. The following are its most serious disadvantages:—(1) the action of the powder, in whatever form it is applied, is not a permanent one in the open air. If it is applied to a plant, it immediately kills the insects on the plant with which it comes in contact, but it is perfectly harmless to all insects which come on to the plant a half an hour (or even less) after the application; (2) it acts in the open air—unless, perhaps applied in very large quantities—only upon actual contact with the insect. If, e.g., it is applied to the upper side of a cotton leaf, the worms that may be on the other side are not affected by it; (3) it has no effect on insect eggs nor on pupae that are in any way protected or hardened. These disadvantages render pyrethrum in some respects inferior to arsenical poisons, but on the other hand it has the one overshadowing advantage that it is perfectly harmless to plants or to higher animals. In a closed room the effect of pyrethrum on insects is more powerful than out-doors. Different species of insects are differently affected by the powder. Some resist its action most effectually, e.g., very hairy caterpillars and especially spiders of all kinds; while others, especially all hymenoptera, succumb most readily. In no cases are the insects killed instantaneously by pyrethrum. They are rendered perfectly helpless a few minutes after application, but do not die till some time afterwards, the period varying from several hours to two or even three days, according

to the species. Many insects that have been treated with pyrethrum show signs of intense pain, while in others the outward symptoms are less marked. Differences in temperature and other meteorological changes do not appear to have any influence on the effect of pyrethrum." The modes of application are then given in the report: they are four in number—in powder, fumes, alcoholic extract, and in decoction, but any of the methods would be found extremely expensive, if tried on field cultivation on a large scale.

MERGUI EXPERIMENTAL PLANTATION.

THE province of British Burmah is not behindhand in the matter of experimental plantations of economic products. Last week we noticed the result of the experiments tried in two gardens in the Arakan Hill tracts, and now we have before us a report by Mr. C. W. Palmer, Deputy Conservator of Forests, South Tenasserim Division, on the Mergui plantation, for the year 1884-85. Mr. Palmer's report, we may premise, is brief to abruptness. For instance, we are not told what area the plantation occupies, what the soil is like, whether alluvial, deluvial, sandy or clayey, rich or poor; whether the facilities for irrigation were favourable or otherwise, or, in short, anything calculated to make the report both interesting and instructive. There is not a word as to how the several plants cultivated were treated; whether any manures were used, and if so, of what kind. We are therefore constrained to characterise this report as decidedly *bald*. The opening paragraph runs as follows:—

There are 1,350 bearing Liberian trees, 708 young trees, and 2,254 seedlings. The growth of this coffee has been very fine; the bearing trees are 8 to 12 feet in height, age 3½ years, and gave last season a heavy crop. It is not possible to give any definite quantity of coffee produced, as the whole amount was collected by the plantation gang.

This affords a fair idea of the style of this report; the succeeding paragraphs, six in number, are strikingly monotonous. We make out that there are 920 trees of the Arabian coffee in a bearing condition, and 1,288 seedlings; and that the produce from these was very small; therefore, all the seed was sown on the plantation. There are cocoa trees which appear to thrive well, and are expected to form pods. The nutmeg is also said to have done well, the only difficulty being found in getting the seeds to germinate. The Vanilla creeper is reported as not only thriving well, but that it has flowered. Mr. Palmer says:—"I tried my hand on fecundating [we presume he means fertilizing, as this is the term used in botany.—Ed., L.A.] these, but am afraid I have not succeeded. I cannot understand Mr. Connor's mode of fecundation." That an officer holding the post of Deputy Conservator of Forests should make such an admission, and display such ignorance of the elements of botany, passes our comprehension! The word "fecundation" is used only when applied to animals. Its synonym, when applied to the vegetable kingdom, is "fertilization." We trust Mr. Palmer will bear this in mind when he is called upon to use the word on a future occasion. The report, we regret to have to say it, is utterly devoid of interest or information, and we are not surprised that the Officiating Secretary to the Chief Commissioner of British Burmah should make the following remark:—

At the time this garden was started, the Chief Commissioner directed that the experiments should be chiefly confined to the cultivation of coffee, cardamoms, vanilla, cocoa, as well as tea, as these were the products which Government was anxious to introduce into the neighbouring district of Tavoy. The present report makes no mention of either cardamoms or tea, and it is not known whether the cultivation of these plants has been abandoned. The report might with advantage give more particulars regarding the experiments made.

We note that the usual grant for this plantation is to be continued for the current year; but we take this opportunity of expressing a hope that the Chief Commissioner will select some officer more fitted than Mr. Palmer to carry out these experiments, as the results of such experiments are likely to have an important bearing upon the future growth of economic products in British Burmah, and which our officers should endeavour as far as possible to promote. It is to the interests

of the State and the people that we should have properly written reports, dealing in sufficient detail—technically, as far as possible—upon these experimental plantations.

DESTRUCTION OF WILD ANIMALS.

A RECORD such as that presented by the returns of the destruction of wild animals in the Madras Presidency for the year 1884, will scarcely, we venture to think, find a parallel in any other country in the world outside of India. One shudders to think what it must have been a hundred years back! The system of giving rewards for the destruction of dangerous animals has been in force for many years, and yet, after a whole-sale killing during these years, the total number of animals destroyed during the year 1884, in the Madras Presidency alone, amounted to 4,033 of all descriptions, compared with 2,708 in the previous year; while the sums paid as rewards increased from Rs. 64,136 in 1883, to Rs. 1,16,246. The various species of animals killed, and the number of each species, compared with the results of the previous year, are as follows:—

	1884.	1883.
Elephants	6	0
Tigers	321	185
Panthers and Leopards	2,193	1,565
Bears	541	298
Wolves	280	93
Hyenas	715	457
Other animals	25	109
Total	4,033	2,708

The "other animals" include, for the most part, foxes, jackals, and wild boars. The foregoing figures show a great improvement over those of the previous year.

The total loss of human life, and of cattle, by wild animals and snake-bite, is detailed below, in comparison with the figures of 1883:—

	Human Lives.		Cattle.	
	In 1883.	In 1884.	In 1883.	In 1884.
By Elephants	5	5	1	6
" Tigers	267	139	3,460	3,129
" Panthers and leopards	48	44	4,418	3,701
" Bears	28	8	30	68
" Wolves	3	1	416	336
" Hyenas	6	0	308	333
" Other animals	24	58	188	183
Total	382	255	8,821	8,761
By snake-bite	1,267	1,191	278	304
Grand Total	1,649	1,446	9,099	9,065

It will thus be seen that there is a decrease of 202 in the loss of human lives, compared with the previous year, although the decrease in cattle is inappreciable. But what strikes us as curious, is that by far the largest number of lives lost were by snake-bite; and what is still more curious, there is, apparently, no reward offered for the destruction of snakes. It is pretty generally known that natives will not, as a rule, kill snakes, owing to superstitious beliefs; but we venture to think that if rewards were offered, it might act as an incentive to the extermination of these reptiles, while it would, at the same time, grease the conscience of the more superstitiously inclined. That this can, and has been, the case, note the remark made by the Special Assistant in Ganjam, who explains the large increase in the number of animals killed in that district as follows:—

"The maximum reward being now paid in all cases has had the most satisfactory results. In several places regular cheetah traps are used; in all places pit-falls are dug for wild animals to fall into. The last is quite an innovation, as from superstition the *Rhonds* used to be afraid of slaying a cheetah for fear of destroying one of their ancestors."

[The italics are ours.] It also appears that the full rewards sanctioned have not always been paid; that, in consequence, parties have, in some cases, not come forward to receive their

rewards. We are glad to see, however, that the Madras Government has drawn the particular attention of Collectors to this point. We also note that in the case of Madras, the low average is said to be due to rewards not having been paid in some cases. This has also engaged the attention of the Madras Government, and we hope to see better results next year.

There is another point to which we would direct attention, viz., the small number of the "other animals" destroyed. Jackals are generally believed to be harmless, unless in a rabid condition. We note, however, that there were no less than fifty-eight persons killed by "other animals," while in Malabar one person was actually killed by a porcupine. The total number of "other animals" destroyed during 1881 was 25, and the rewards given amounted only to Rs. 3. This would give an average of one anna and eleven pie per head of animal, which is certainly not a very strong inducement for their destruction. We hear almost every day of jackals carrying off infants in arms and attacking young children. Unless more encouragement is given, by the offer of reasonable rewards, satisfactory results cannot be expected in this direction.

The return under review brings to light something of the ludicrous as well, by a display of ignorance of the character of "wild animals," which we were not prepared to expect from an officer of the rank of Collector. It will interest our readers to learn that the Collector of Madras has included in his return the number of persons who died of rat-bite, dog-bite, kick by a horse, and scorpion-sting; and in Madras a person killed by a bull is shown under "other animals." Upon this the Madras Government naively observe that "these have been excluded from the Board's statement, as the deaths were not caused by wild animals." The following table shows the number of persons and cattle killed by wild animals, the number of wild animals destroyed, and the amount of rewards paid for their destruction, in each of the past five years:—

Years.	Number of Wild Animals destroyed.	Rewards granted.	Number of Persons killed by Wild Animals.	Number of Cattle killed by Wild Animals.
		Rs.		
1880	1,24	16,580	223	8,667
1881	1,429	20,251	238	8,668
1882	2,056	44,171	275	8,770
1883	2,708	64,133	382	8,821
1884	4,038	1,16,246½	255	8,761

So that during the past five years there have been no less than 11,509 animals destroyed, at a cost of Rs. 2,62,324, which killed 1,373 persons, and 43,667 cattle; and this in the Madras Presidency alone. A ghastly record, truly!

Miscellaneous Items

Fifty thousand rupees' worth of copper coinage, forwarded by the Bombay Mint, has arrived in Bangalore for the Mysore Government.

Lord Dufferin having sent the Sultan a collection of rare and very valuable Indian plants, his Majesty, who is very pleased with the present, ordered his thanks to be conveyed to the Viceroy.

CHOLERA and small-pox still prevail in a few districts in Berar. Fever, measles, and bowel complaints are reported in all districts. Cattle are free from disease, except in the Basim district. Sowing operations have nearly been completed.

THE Eurasian and Anglo-Indian Association of Madras is endeavouring to form an Agricultural Library at its colony in Whitefield for the benefit of the settlers there, and it is with very great pleasure we note that Messrs. Higginbotham and Co. have made a most liberal gift towards the project in the shape of one hundred volume of works, bearing principally on agricultural and kindred topics. This will form a most valuable nucleus, added by the contributions of the several departments of Agriculture in India and Burmah, whose sympathy has been enlisted.

THE revenue of the colony of Australia for the financial year, ending June 30, amounted to £7,449,878, an increase of £918,648 as compared with the preceding year. The revenue for the quarter ended June 30 amounted to £2,074,342, an increase of £230,337 on the corresponding quarter of last year.

At the office of Mr. Grant, the Collector of Bombay, four plots of land situated at Middle Colaba, near the Wodehouse Bridge, were put up for sale. There were only five persons present: three Jews and two Parsees. After the conditions of sale had been read, those present declined to bid as the upset price of Government was Rs. 10 per square yard. The plots are numbered 5, 6, 7, and 8, and their superficial areas are, respectively, 1,705, 1,686, 1,624, and 1,548 5-9 sq. yards. It appears that an offer has been made to Government of Rs. 7 8 per sq. yard. No sale was effected.

FROM next month the sales of Cinchona bark on account of the Government of Madras will be held at Madras on the first Monday in each of the four months of September, October, November and December. The sales will be by public auction, and the Government guarantees that for the next two years the quantity offered will be not less than 70,000 lbs per annum, in quantities of not less than 17,500 lbs. at each of the four monthly sales. The bark offered will for the next two years at any rate, be the various varieties of "crown" exclusively, and samples accompanied by analyses made by the Madras Government (Jubologist will be available at Madras for a fortnight before the sales and at the India Office for intending purchasers on specified dates.

THE Committee of the Kandy Agricultural Art Exhibition has set an excellent example to the older institution of Colombo by publishing its reports and accounts so shortly after the show, and with most satisfactory results, showing a balance in hand to be carried to the credit of next year's account, of Rs. 1,059. As a correspondent has very properly suggested, the Colombo Committee should be called upon to make known its proceedings and the state of its accounts, fully a year having passed without any statement having been made. It is pointed out with some force that this Committee cannot well make an appeal to the public for another show until it has rendered an account of its stewardship in the past. The members of the Committee should call upon the Treasurer and Secretary to come forward with some sort of statement.

So early as December last, certain inhabitants of the villages of Babaim, Essar, Borwalli, Simpall, Dyear, and other places of the Salsette Taluqa, traders in fish-manure, applied to the Collector of Tanna, representing to that official the impassable state of the roads leading from Bombay to Ghorebunder, and praying that steps be taken to extend the said road for the purposes not only of ordinary traffic, but also for the greater facilities of trade. While the B. B. and C. I. Railway Company, with an eye to business, have seen the advantages of traffic with these villages, the Government authorities have remained strangely inactive. Meanwhile, the poor villagers, who maintain themselves principally by this fish-manure trade, along with a local trade of minor importance, have had to contend with great difficulties, as appears from the correspondence which has been passing between them and the local authorities.

IN December, 1884, the Madras Government made an engagement with M. Cornet for the sinking of an artesian well in or near Madras. The depth of this well was estimated at 203 feet, and the cost at Rs. 15,000. Upon the recommendation of Dr. King, of the Geological Survey, who selected the People's Park as the best spot for an artesian well, borings were commenced in March last, and after reaching a depth of 58 feet, granite rock was met, which was found very hard and difficult to bore through. In order to ascertain whether this granite was merely a detached boulder, or part of the strata of the earth in the locality, trial borings within a diameter of 60 feet were made, but they all showed that the same granite was to be met with. The boring operations in the Park were accordingly abandoned, and the result of the search of the country around indicated that a stratum of granite existed for two miles north of the Fort and some miles inland. This being the case the Government has stopped the operations for the present, pending a selection of some other site by Dr. King.

AN advertisement will have been noticed a few days ago in the columns of the Pioneer, conveying a public-spirited offer from Mr. G. Jasper Nicholls, C.S., to send, at his own expense, anyone applying a supply of seeds of the *Bambusa katang*. But probably few people not botanists appreciated the meaning of the offer. The *Bambusa katang* is not only the largest bamboo grown in India, outside of Burmah and Assam, but from its habit of flowering only once in 55 or 60 years it is also excessively rare. Some specimens exist at Jubbulpore, where they are remarked by every visitor for their beauty and size; but until these should have arrived at the time for maturity and decay, in another 10 years or so, it was not known that there would be any seed procurable, in these parts of India at any rate. Mr. Nicholls, however, was fortunate enough to discover a clump in full flower recently on the banks of the Mattanadi, in Katoora, and knowing what it was, had all the seed scrupulously collected by the villagers, and in the hope of getting the tree widely distributed over Upper India, he is now offering it to the public. The *Bambusa katang* grows to a height of over 60 feet; its tall stem gives the best natural material for scaffolding, and in beauty as well as size it may claim to excel all the varieties of bamboo known to the Ganges plain and Deccan highlands.

Selections.

SERICULTURE IN FRANCE.

From Monsieur NATALIS RONDOT, President of Section in the Permanent Commission of Customs Values, To his Excellency the Governor-General of British India, Dated Paris, 17th June 1884.

I HAVE the honour to submit to your Excellency a circular and series of questions which the Chamber of Commerce of Lyons has distributed regarding sericulture and the silk industry.

The Chamber of Commerce of Lyons has founded, on my recommendation, a laboratory for the study of silk-worms and silks, and is collecting the materials for the study from all parts of the world.

The chief aims of the work to be undertaken will be to complete the nomenclature of all the silk-producing families, to describe scientifically each species, variety, sub-variety, race, while at the same time determining precisely the qualities of the cocoons and of the silks which they yield. Trials of a technical nature will, therefore, accompany the more scientific investigations.

India, if we believe several observers, among others Captain Hutton, possesses several species of domesticated silk-worms which are still at the present day unknown in Europe.

Entomologists and rearers of silk-worms in France and Italy have not seen nor had an opportunity to study and experiment with the species which, under the names of *Bombyx textor*, *B. fortunatus*, *B. croesi*, *B. sinensis*, *B. arracanensis*, furnish India with crops of cocoons.

The Chamber of Commerce of Lyons, and with it the entire silk industry, would attach great value to the possession of selected specimens of worms, moths, cocoons, and silks of these species, and all others reared or wild in India.

India has of course other silk-worms which are interesting in more respects than one; and I venture to hope that your Excellency will be willing to sympathise with us in the project of general usefulness which we have in view.

The studies which are to be undertaken will profit all those who follow sericulture. The results will be made public.

The first studies will be confined to the materials furnished by the Italian Government; and numerous rearers in different countries are co-operating in this work which is one of an entirely new character.

* CIRCULAR.

From the President of the Chamber of Commerce of Lyons.

THE Chamber of Commerce of Lyons, on the proposal made by M. Natalis Rondot, has decided that it would be interesting, and of practical utility to undertake a series of studies on the silk-producing worms of every country, on the cocoons of these worms, and on the silk which can be obtained from them by reeling or spinning.

Our Chamber proposes to itself a two-fold object:—

(a) to determine, with the greatest possible precision, the genera, species, and varieties of the domesticated, semi-domesticated, or wild worms.

(b) to ascertain the richness in silk of the cocoons, envelopes or silky coverings, the nature and quality of the silk obtained, and in particular the colour, fineness, tenacity, elasticity, yield of raw silk, and the aptitude for taking dye, &c.

Our Chamber undertakes these researches and experiments chiefly in view of the practical results which it foresees; it will prosecute them with perseverance as much in the interest of sericulture as in that of the manufacture of fabrics and of the commerce in silk. This study will at the same time be of profit to science, and we hope that it will help to clear up more than one obscure point in the history of the silk-producing worms.

A permanent Commission appointed by the Chamber of Commerce will direct the work annually and report on the results obtained.

The materials on which the experiments and studies are conducted will be deposited in the Museum of the Chamber of Commerce.

This project which is quite a new one, and is surrounded by so many difficulties, will be profitable to all; it cannot be brought to a satisfactory conclusion without the active and intelligent co-operation of all who value the improvements which the course of events introduces into the silk industry, as well as the discoveries in this hitherto neglected field of science.

We shall be glad, Sir, to reckon you among our collaborators in the work which we are undertaking, and to preserve your name as one of the donors of the specimens, now solicited, for our Museum of Art and Industry.

You will find annexed two series of questions accompanied with explanatory notes,—the one concerning the species of domesticated silk-worms, the other the species of semi-domesticated and wild silk-worms; we solicit your careful consideration and favour of early replies.

It is, of course, understood that our Chamber will be glad to refund all the expenses which you may incur.

CHAMBER OF COMMERCE OF LYONS.

INQUIRY INTO, AND STUDY OF, SILK WORMS.

Questions regarding the domesticated or mulberry silk-worms.

1. What species or variety do you cultivate? Where is it found wild or semi-wild? Where and under what name do you purchase your seed or eggs?
2. Is your insect pure or a hybrid; and, if the latter, out of what stock has it been produced?
3. Is the insect univoltine, bivoltine, trivoltine, polyvoltine?
4. How many moultings does the worm go through?
5. What is the colour of the skin of the worm at each age, particularly in the last age?
6. Do all the worms of one brood come out the same colour?
7. Is the worm characterised by spots, streaks, tubercles, horns, hairs, or has it a spur or other peculiarities?
8. When does the rearing commence, and how long does it last from the hatching of the egg to the moulting of the worm?
9. What species or variety of mulberry plant serves as food for your worms? By what name is it locally known?
10. What is the nature of the soil in which it grows?
11. Is the leaf given to the worm after being detached from the twig, or is it left attached to them?
12. What is the average weight of fresh cocoons obtained per English ounce of eggs? (The Indian *rola* may be taken as equal to 2 ounces.)
13. How many cocoons go to a pound (or $\frac{1}{2}$ *seer*)?
14. How many pounds of fresh cocoons yield one pound of silk?
15. If more than one crop is obtained in the same year, give for each crop detailed information as to time of the year, duration, characteristics of the broods or swarms, moulting, average produce, &c. How many successive hatchings take place in the year? What is the name given to each successive hatching and crop?

Questions regarding semi-domesticated or wild worms which produce cocoons, envelopes or silk coverings.

1. Under what vernacular or commercial name is the species known in the country?
2. Give the vernacular names in Oriental character.
3. Are the specimens the product of semi-domesticated or wild worms? (By 'semi-domesticated' is meant worms hatched in-doors and transferred to trees in the open air under supervision. Wild worms are entirely independent, and are left to themselves in the open air.)
4. Is the species univoltine, bivoltine, trivoltine, polyvoltine?
5. What is the ordinary number of successive hatchings (semi-domesticated or wild) during the year?
6. How many moultings does the worm pass through?
7. What is the colour of the skin of the worm? (If possible, the age at which the observation is made should be stated.)
8. Is the worm characterised by spots, streaks, tubercles, horns, hairs, or has it a spur or other peculiarities?
9. Have you observed any differences in the colour of the skin, or in other respects in individual worms of the same brood? (Compare with question No. 6 above.)
10. At what time of the year does each successive rearing commence and finish? What is the name given to each rearing? (It would be very interesting to have specimens of each rearing, but if the product of only one be sent, indicate precisely what relative position it occupies amongst the different rearings of the year.)
11. How many cocoons go to a pound?
12. Are the cocoons open or closed, and are they suspended to branches by a stalk (peduncle), or are they closed within a leaf (or leaves) of the tree, or in a silky envelope?
13. Send the silky envelope, whether thick or thin, within which the cocoons are spun or the worm transformed into the chrysalis.

14. Are the cocoons reeled or spun (combed and carded to fibre, thereafter spun like cotton)?
 15. What is the price of a pound of dry cocoons?
 16. How many pounds of dry cocoons are necessary to obtain one pound of silk reeled or spun?
 17. Give the names (scientific or vernacular) of the trees or shrubs on which the worms feed?
 18. In what kind of soil do these grow? (In the cases where the same species of worm produces cocoons of different colour or nature, according to the tree on which it feeds or the soil in which the plants are grown, send specimens to illustrate this peculiarity.)
- The preceding questions are those to which the Chamber of Commerce of Lyons invites particular attention, but the following are also important:—
19. Is the species abundant?
 20. What method is adopted in reeling the silk, and what liquid is used to soften the cocoon?
 21. To what use is the reeled or spun silk put in the country?
 22. What means are employed to check the ravages of destructive insects (destructive to worm, cocoon, or plant)?

EXPLANATORY NOTES.

1. *Transmission of dead specimens.*—It is recommended that a collection should be made of worms, cocoons (envelopes or coverings of silk), moths, and eggs of every species which produces silk whether domesticated, semi-domesticated or wild.

As regards domesticated species, those should be chosen which are supposed to belong to a primitive type, or pure race. When hybrids are selected, all that is known of the ancestral types should be stated.

It is requested that, as far as possible, each well defined type be represented by a set of the most characteristic specimens.

("A few exceptionally large samples, as also diseased or bad specimens, would also be interesting if declared as such; but the chief collections should represent the average condition."—G. W.)

Moreover, every worm which produces a silky substance deserves to be studied, and none should be excluded, even though it should be already well known or commercially utilized. It is of great interest to study and compare every silk-worm and its products.

It would, for example, be exceedingly instructive to collect sets of specimens, in the case of a polyvoltine species (worms, cocoons, and moths) of each successive rearing; and also to preserve, in the case of the same species, the worms, the cocoons, and the moths which exhibit exceptional and notable differences.

2. *Label.*—All the specimens of the same species should bear the same serial number and the same label, so as to prevent confusion in unpacking and during the preliminary classification.

("It is an excellent plan to have a distinctly different coloured thread attaching the labels of each set, so that, should by any accident the ticket be removed, the thread may assist the identification."—G. W.)

3. *Worms.*—The worms should be preserved in alcohol (in the absence of alcohol in a strong alcoholic liquor) in well stoppered bottles, of which the stoppers should be securely fastened. The age of the worm should be indicated. A dozen worms at least are requisite of each species of form; and it would be well, as has been said above, to add worms exhibiting differences in colour, marks, horns, as also sets of worms after each moulting, &c.

Since alcohol alters the colour of the skin of the worm and often changes the appearance, it would be, well, when possible, especially in the case of worms of the fourth age, to make a coloured drawing life-size, in order to show the exact colour and size of the worm.

("With a little practice, dry worms may be prepared, which will be found to preserve all the natural colours and external peculiarities. Drop live worms into a bottle of strong alcohol so as to kill them quickly. Get a slab of glass or marble, and, as soon after killing the creature as possible, lay it on the slab with the head towards the operator. Roll over it a pencil firmly pressed and slowly, from head to anus, as so to expel the entire contents. Catch up the tail extremity and insert at the ruptured and slightly enlarged anal opening a pointed piece of fine glass tubing attached to an india-rubber ball syringe. Through the contraction of the ball syringe causes in this way a current of air to pass into the worm until it has been dilated to the natural size. While doing so, hold the glass rod tipped with the flaccid and dilated insect over a gentle heat from a spirit lamp. It will harden in any position you may desire, and in the great majority of cases will so preserve its colouring and markings that, if placed upon a dried specimen of the plant upon which it naturally feeds, it will appear

alive. Unless great care is taken, however, the specimens may be unnaturally dilated, but for handsome collections illustrating the plant and insect in all its transformations, this will be found an exceedingly interesting mode of preserving the caterpillars."—G. W.)

4. *Dry (or desiccated) cocoons.*—Cocoons in a dry natural state, i.e., not deprived of their outer fibres, should be selected from the best specimens. They should represent the normal type of the species. One pound at least is required for experimenting with the silk. In default of this quantity, as many cocoons as possible should be sent.

Take the necessary measures to prevent the cocoons from being destroyed by parasitical insects during the voyage.

5. *Moths.*—The moths should be placed with extended wings in envelopes of soft paper. Several specimens would be useful for the scientific studies, and for exhibition in the Museum.

("In drying large-bodied Indian insects, it is often necessary to carefully cut open the body below and partially remove the contents, placing a small piece of cotton wool within to prevent contraction."—G. W.)

6. *Eggs.*—The eggs should be, as far as possible, preserved in the natural layers or deposited on card board, cloth, or on the leaves of the tree on which the worm feeds, in order to show their natural grouping.

("In the same manner the cocoons should be sent in the natural or undisturbed condition in which they are formed by the worms. This is particularly interesting in the case of insects which form great aggregated masses."—G. W.)

7. *Leaves and flowers of the trees which serve as food.*—The tree on which each species feeds should be represented by one or two dried flowering or fruiting leafy twigs.

("These are easily enough preserved. Cut off a twig, say, one foot or a foot and half in length. It should have 2 to 3 leaves with a few flowers or a fruit. Place it between sheets of soft country paper unglazed, or simply ordinary blotting paper. Over the top put a couple or so of books to keep the specimen flat. Change into fresh paper two or three times, e.g., about every alternate day until dry. The same paper will last for years if dried at the fire or in the sun between each time it is used."—G. W.)

8. *Silks.*—It would be desirable to add to the collections of insects small samples of their corresponding silks (such as are obtained in the locality), viz., reeled, spun, waste, chassam; also tram and manufactures.

In conclusion, we particularly desire precise information as to the names given in the country to each form of insect, also the tree on which the worms feed; and all information that can be given in addition will be gratefully received.

9. *Transmission of live specimens of eggs of silk worms and of seed cocoons.*—It is intended to compare dead worms or trade sample with worms reared in the laboratory and observed in their living state, as this is indispensable to arrive at the object which is in view. It will therefore be necessary to rear either the live eggs, or the seed cocoons which may be received.

In packing live eggs and cocoons the following precautions should be taken, particularly if the voyage is to last some weeks:—

Shallow boxes should be used, pierced with holes for ventilation, and lined inside with perforated paper. The cocoons should be strung by a thread passing through the silk, but without penetrating the shell. These should then be suspended to the opposite sides of the box, in parallel lines, the lines being kept apart from each other.

During the voyage, should the chrysalides reach maturity and make their escape from the cocoons, the moths will couple, and the females lay their eggs freely. On arrival at their destination, the interior of the box will be found strewn with eggs in good condition for hatching.

Live eggs should never be sent in hermetically closed boxes with camphor. Each species should be placed in separate small boxes, pierced with holes and lined with perforated paper. The cocoons should be either placed in small boxes pierced in the same way, or in cloth of open texture so as to provide continuous ventilation.

Note.—The above is a free translation of the original correspondence and circular. It has been modified only where necessary to meet the requirements of India. A few additions have been made, but all departures or additions are indicated by the inverted commas placed before and after such passages. The word a 'brood' and a 'rearing' (see No. 9 of the second set of questions) are intended to have the following meaning:—*brood* or *swarm*, the produce from the eggs of one individual; *rearing*, the whole hatching or batch at a certain season—an aggregation of broods. The weights have been changed from French to English and Indian.—G. Watt, on

Special Duty with the Government of India, Revenue and Agricultural Department.)

The following extract from the "Dictionary of the Economic Products of India," presently being published by the Revenue and Agricultural Department with the Government of India, may be found useful. It gives a simple classification of the plants upon which the Indian wild or semi-domestic silk worms feed.

Ailanthus glandulosa, Desf.

Incorrectly called the Japan Vernish Tree, *Kay*; *Get-terbaum* (*Tree of the Gods*), *Ger*; *Vernis du Japon*, *Fr*.

HABITAT.—A lofty tree, met with in North India, most probably introduced from Japan. Extensively cultivated on the continent as an avenue tree along with the tulip-tree, the horse-chestnut, the plane, &c. The leaves are not liable to be attacked by insects, and therefore, until the first frosts of November, the tree remains covered with its large leaves, affording a grateful shade.

BOTANIC DIAGNOSIS.—Leaves often exceeding 1 foot, pubescent or sub-glabrous; leaflets very numerous, coarsely toothed at the base; stamens exserted; filaments several times the length of the anthers. Samara 1 inch by $\frac{1}{2}$ inch, membranous linear oblong.

SERICULTURE.—Upon the leaves of this tree the wild silk-worm *Attacus Cynthia*, *Drury*, is reared in Europe; and, indeed, this is perhaps the most successful tree for the experimental rearing of different species of silk-worms. It grows freely, even in England, and the insect thrives upon it.

Attacus CYNTHIA, *Bombax Cynthia*, *Olivier*, or the so-called wild eri-silk, of Assam, exists entirely in a wild condition, and its cocoons, although often plentiful in the jungles, are rarely collected. It is especially common in Cachar and in Kamrup (in Assam), extending west through Sikkim to Mussoorie and Simla, with an average altitude of from 1,000 to 7,000 feet.)

It is anticipated that the rearing of *Attacus Cynthia* upon this tree may become an established industry in Europe.

In connection with the subject of the value of *Ailanthus* as a food for silk-worms, it seems highly desirable that experiments be performed in India, with the object of producing a *reliable hybrid eri*, which would still preserve the valuable property of feeding upon an annual plant such as the castor oil. The *Ailanthus glandulosa* has proved a most convenient plant for experimenting with in Europe, but both for experiments in India and for the following plants are those which would most probably afford the means of prosecuting the investigations necessary for the production of hybrids of Indian indigenous silk-worms. The plants have been grouped in a way which brings out the overlappings in habit, as also some of the structural affinities of the more important species of silk-worm.

TEMPERATE PLANTS.

* ACTIAS AND CALIGULA SERIES.

1st.—Rosaceous plants, such as *Prunus Cerasus* (the wild cherry) *Pyrus communis* (the wild pear), and *Cydonia vulgaris* (the wild quince); small trees met with in India on the Himalaya and the hills of the Eastern Peninsula at altitudes of from 5,000 to 10,000 feet.

The following species of silk-worms feed upon these plants in their wild state:—*Actias selene*, *Caligula simla*, *C. thibeta*.

2nd.—*PRUNUS OVALIFOLIA*, an exceedingly plentiful, ericaceous, small tree coming into fresh green foliage just before and flowering during the rains on the Himalaya and mountains of the Eastern Peninsula, at altitudes of from 4,000 to 8,000 feet.

The following insects feed upon it:—*Actias selene*, *Caligula thibeta*.

** ACTIAS AND ATTACUS SERIES.

3rd.—*AILANTHUS EXCELSA* and *A. GLANDULOSA* (the former would most probably not succeed in England.)

The following are the insects regularly found feeding upon these trees in India:—*Attacus ricini* (the eri silk-worm) and *A. cynthia*.

4th.—*CORIARIA NEPALENSIS* (*Masuri*, Hind.; *Bhojini*, Nepal) a small leafy bush, belonging to the natural order Coriariaceae (allied to Moringaceae and Leguminosae), plentiful on the Himalaya and mountains of the Eastern Peninsula, Burma, and the Straits; altitude from 5,000 to 10,000 feet. Should grow freely in England. This is one of the most curious plants enumerated in this list, and for the purpose of rearing hybrids seems the most hopeful.

The following insects feed upon it in their wild state:—*Actias selene*, *Attacus canningi*, and *A. ricini*.

WARM TEMPERATE PLANTS.

*** *ATTACUS*, *ANTHEREA* and *CRIOLA* ON THE *ERI*, *MUNGA*, *CRIOLA*, and *TUSSER* SERIES.

5th.—*SYMPLOCOS CHATEAULOUX* (*Lo*, *iq*, *Ph*; *Loth*, *Kansau*, *S. GRANDIFLORA*, and *S. HAMBOSSIMA* (*Loth*, *Hind*; *Kals Kharini*, *Nepal*). Small trees or shrubs on the Himalaya and lower hills of India ascending to 7,000 feet in altitude.

The following insects are known to feed upon these plants, or are actually fed upon them, in their semi-domesticated condition:—*Attacus atlas*, *A. ricini* (small red form of *eri*), and *Antheraea assama* (the *Munga* silk-worm).

6th.—*RHINUS COMMUNIS* (*Arand*, *arandi*, *Hind*.) (the common castor oil plant), cultivated in the plains of India and in the hills up to an altitude of 7,000 to 8,000 feet. Grown as an annual in England, ornamental forms having been produced by the gardeners.

The following are the insects which feed upon this plant:—*Attacus ricini* (the *Eri* silk-worm).—This is its principal food in domestication and also in its wild state. *A. cynthia* and *Antheraea mylitta* (the *Tusser* silk-worm).

7th.—Species of Laurels, in India, chiefly *Macchilus odoratissima* (*Kanala*, *Hind*, *Sam*, *Ass*.) (up to altitude 8,000 feet, the principal food of the *Munya*) and *Tetrathora polyantha* (*Sitambar*, *Nepal*; *Adakuri*, *Ass*.)

The following are the insects which feed on these plants, as also on one or two allied species of laurels:—*Antheraea assama* (the *Munga* silk) and *Criola trifonestrata* (the common wild, yellow, reticulated cocoon of Burma and of the south and west of India.) Upon the former tree these insects chiefly feed, both in their wild and semi-domesticated conditions.

TROPICAL PLANTS.

It is necessary to add to the experimental plantation one or two other trees with the view of admitting of a more thorough investigation of the forms and possible hybridisation of the *tusser* silk-worm.

* * * * THE TUSSER SERIES.

8th.—*ZIZYPHUS JUJUBA*, (*Ber*, *Hind*.)

9th.—*LAGERSTROMIA INDICA* (*Sida*, *Hind*, *Bong*.)

Two small trees or bushes which experience has shown to be perhaps upon the whole the best plants for the cultivation of the *tusser*-worm.

10th.—*TERMINALIA TOMENTOSA* (*Sain*, *Hind*; *Pissal*, *Beng*.) and one or two allied species (the myrobolan or wild almond family). These are the trees which the *tusser* worm seems to prefer most in its wild condition.

In the above brief indication of the food materials of certain silk-worms, only the more important species of the general most likely to afford useful hybrids have been mentioned.

It is interesting to observe that this climato-botanical classification brings the indigenous silk-worms of India into groups closely corresponding to those formed upon a more scientific principle. It would almost seem that hybridisation to be successful must pass through these natural affinities. It is remarkable that none of the Indian Saturniidae (the family to which the foregoing silk-worms belong) show the slightest tendency to feed on the plants upon which the mulberry silk-worms (the *Bombycidae*) are reared—a fact which gives some weight to the idea that the latter are not truly indigenous to India. (For further information consult the account given under "Silk.")

Ailanthus MALABARICA, *DC*.

VERN.—*Peru*, *peru-marattup-puttai*, *maddi-pal*, *Tam*; *Peruparum*, *pedda-mann-putta*, *maddi-pal*, *Tel*, *Peru-marattoli*, *mattip-pal*, *Malt Mudde-dhupa*, *bagd dhupa*, *Bomb*, *Guggula-dhupada*, *nd*, *Mahr*; *Dhup*, *buga dhup*, *gogul-dhup*, *Kan*, *Manda-dhupa*, *Hassan Mattipas*, *Anamalla*. No Burmese name; *Kambahin*, *walibiling*, *Cingh*.

HABITAT.—A large, deciduous tree, of the evergreen tropical forests, abundant in the Western Ghats; rare in Pegu, but met wild on the eastern slopes, and in the valley of the Taitouang. Often planted in South India for ornamental purposes.

BOTANIC DIAGNOSIS.—Leaves very large; leaflets almost entire nearly glabrous. Stamens exserted upon filaments many times longer than the anthers. Samara large rounded at both ends, not twisted.

CONCERNING ENSILAGE.

INDEPENDENCE, Kas., May 28, 1885.

EDITOR, *Farmers' Review*: I have been watching with interest all the matter pertaining to silos and ensilage that has been published in the *Review* for about five years, also all other sources that came under my observation. As the matter has progressed, new principles seem to be discovered that control the

preservation of green fodder. It now seems that it is possible that green food may be preserved in a nearly perfect state without expensive silos, and the very troublesome work of weighting down the mass. In the series just published, I am almost led to believe that in the ordinary barn, we may make use of this. In my barn, which is 30 x 40 feet, and 20 feet high, I have a bay 10 feet wide across one end, with the obstructions, and barn floor to drive in the hay. I thought when I completed the study of that series of articles that I could cut up my fodder corn and pack in the bottom of this bay, leaving a space of two feet on the ends and back side, filling three or four feet at a time, and then allow the heat to generate to required point, 122 degrees Fahrenheit, and another layer about same thickness, and so continue until I had a mass 12 to 16 feet deep. I thought that I could put up my hay in small, round stacks on the meadow, and when the fodder was secured, could draw in and fill to top of barn, and perhaps fill the ends and sides as I progressed, tramping it down to make a tight wall of it. What I wish to know is, will that be a sufficient protection and weight to preserve it? Also, will there be any danger of the heat reaching a point of spontaneous combustion? I have a good cupola for a ventilator. The opinion of the *Review* on this, if given, may help some others as well as your constant reader. I will give the opinion expressed by our county surveyor, W. P. Rushmore, who is also a reader of the *Review*. He was here this week, and told of a man in the East whom he knew fifteen years ago, who had a brick barn with a basement. He hardly allowed his clover to wilt, when he put it away in that tight barn. When the clover came out in the winter, the bloom of the clover even was preserved as good as when it was green.

D. W. KINGSLEY.

The objections to the above plan are these: The fodder corn cannot be built up with a solid face having the two-foot space proposed at back, side, and ends. The three sides would be exposed to the air all the time that the filling proceeds, and when it came to filling in the space left with hay, there would still be air spaces between the hay and the ragged edge of the silage pile, the effect of which would be the spoiling of a good deal of material. Another objection is that the silage will be at the bottom of the bay, and not accessible till the hay was fed out. Our plan would be to partition off a portion of the bay for silage, boarding it smoothly inside with jointed lumber. Fill slowly according to the latest idea, with uncut corn, taking care to pack closely at the sides and corners so that when it settles there will be no air spaces. Ten feet in width at one end of the bay for a silo, if filled ten feet deep, when fully settled will hold over thirty tons. The space above this might be filled with hay, if desired, and first fed out. The secret of sweet silage is the destruction of the germs of ferment—the bacteria, by heating, and then complete exclusion of air. This latter could not, as we think, be secured on the plan proposed, but could on that we have suggested. A few feet in depth of hay on the top of the silage, well packed down at the sides, would undoubtedly furnish all the cover and weight needed. Our correspondent has all the conditions in his barn for cheaply testing the value of silage, and we should be sorry to have him undertake it on a faulty plan that would result in disappointment and disgust. With the silage resting upon the ground, with no air space below, as should always be the case, and filled as proposed, there would be no chance for spontaneous combustion for which air is an essential requisite. Those who advocate slow filling and the heating of the mass as the filling proceeds, claim that the cause of the ferment—the bacteria—being destroyed by a temperature of 122 degrees Fahr. or over, the heat will naturally subside of itself, provided no new germs are admitted by admitting air to the mass. Each addition to the contents of the silo effectually excludes the air from that previously put in, and the presumption is that while the top layer—undergoing fermentation—is hot, the lower ones, from which the cause of the heating has been removed, or rather destroyed, are in process of cooling off.—*Farmers' Review*.

WHAT IS MILK?

Mr. FARMHOUSE MCCONNELL, F.H.A.S., late professor of agriculture at Glasgow, Scotland, now of Essex, England, recently delivered a lecture upon the above question to the agricultural students at South Kensington, London.

The writer had the honor of learning practical dairying from Prof. McConnell, at his large dairy farm in Ayrshire, Scotland, and will ever remember him as an esteemed teacher and personal friend.

The summary of the lecture which we here give is from the columns of the *Agricultural Gazette*.

We notice that the lecturer has been criticised in this country for saying "In butter-making, it is found the animals do best when continually tied up." We beg to defend our friend by saying that it is understood in Scotland that all stabled cows daily receive sufficient out-door exercise to keep them in good health. They are, however, wholly fed inside.

The lecture is reported as follows:—

The lecturer began by stating that milk was defined as an emulsion of fats in a solution of sugar and albuminoids, and that it had both a chemical composition and a definite structure. The average analysis might be given as follows:—

Water	87.25
Butter	3.50
Caseine	3.50
Albumen40
Milk-sugar	4.80
Ash75
				100.00

The various ingredients were perfectly defined, and separate from one another, and kept to pretty nearly the same relative proportions—any variation being due principally to peculiarities of breed.

Under the microscope, milk was seen to be composed of a homogenous fluid, in which floated a large number of globular bodies. On closer examination these globules were found to be composed of pure butter-fats, and it was as yet a debated point whether they had actual skins of caseous matter or not. If they had skins, and were equivalent to little sacs of fatty matter, then the action of churning would be to break the sacs and let out the fats, which would then unite into lumps of butter. On the other hand, if ether (which has the power of dissolving fat) is applied, some of the corpuscles are rendered invisible under the microscope and others are untouched, thus seeming to show that some have no shell. Some authorities say there is no actual skin, but that caseous matter is "condensed" into a thicker coating on the surface of these particles of butter.

PRODUCTION.

To understand how milk was produced, it is necessary to have a clear knowledge of the structure of the cow's udder. The mammary gland consists of two halves of highly developed tissue; each half has two teats (the third is abortive), and each teat is literally a hollow bag fastened on to the bottom of the udder. At the top of each there is a cavity, known as the "milk cistern," and from this there ramify tubes in all directions through the substance of the vessels. These tubes grow smaller and finer away from the teats, until at last they end in microscopically small sacs, which are lined with epithelial cells. These sacs are grouped into globules of three to five, and have a common outlet. It is the function of this cell structure to manufacture the milk, or at least the corpuscular part of it. Part of the milk must, of necessity, be simply transuded from the blood through these cells—the water, for instance—as the outside of the globules is thickly lined with blood vessels; but other parts (and especially the butter globules) are manufactured by the living action of the lining cells. New cells are formed behind the old. These are pushed off, and fall into the cavity of the tubes; but before doing so they had the interior metamorphosed into butter particles, the walls disappear, and normal milk is the result. Colostrum, or the first milk after calving, contains a large amount of these cells in an unchanged condition. The activity of these cell structures can be stimulated greatly by proper feeding and general treatment, and the proportion of solids to water increased by rich food, though at the same time the breed and general characteristics of cows have much to do with it.

VARYING COMPOSITION.

This depends much on food, season of the year, time after calving, etc., but on breed especially. Natural milk may have as little as 83 per cent of water, with some 5 to 6 per cent of fats, or as much as 90 per cent of water, with corresponding poverty of everything else. By feeding we can increase the total solids, but not the proportion of any one ingredient. Oil cakes are not the best foods, for it has been proved that fatty matter given to a cow is not turned into butter, but used up in the body, though it thus indirectly leads to the improvement in the general quality of the milk. On the other hand, albuminoids in the food are directly converted into butter-fats as well as albuminoids in milk, and thus in practice it is found that bean-meal and cotton-cake

(decorticated) are among the best concentrated food for cows. Washy food reduces the total solids and increases the water. Exercise tends to the using up of nitrogenous matter, and in cows it is secreted as casein, so that in a cheese-making dairy the cows should pasture outside, while—as rest tends to the conservation of fat—in butter-making it is found the animals do best when continually tied up.

BREED.

The great fact, however, which influences the yield of special components is the breed of the animals. By artificial selection the Jerseys have been developed into a variety which yields milk containing a 5 to 6 per cent of fat (and over). Under the microscope it is seen that the corpuscles are larger than in the case with Ayrshires—which latter have been bred for cheese-making principally, and therefore, have as much casein as butter in the milk. By keeping the progeny of the animals with the best milk, and judiciously crossing, various breeds have been developed in the course of time whose glands will yield milk rich in one or other of the component parts, and this, irrespective of feeding and treatment. Large butter corpuscles require large gland cells to form them, and these are the result of development. The total solids depends most on food, treatment, etc., and variation of ingredients most on breed. There is no reason to suppose that any breed has as yet reached its "structural limit," and improvement is to be sought in selection, and using butter and milk tests as a guide.—*Farmers' Review*.

SWEET ENSILAGE.

By PROFESSOR SHELTON.

It is natural to feel all the more confidence in Mr. Fry's advocacy of ensilage, since he makes no extravagant claims, and indulges in no high-flown rhetoric about the matter. Many would-be reformers are carried off their feet by enthusiasm that is wanting more or less in discretion; but this is not the case with Mr. Fry, who may be regarded as the original pioneer in the domain of sweet ensilage in this country, and his book is the boiled-down result of much study and experiment. Mr. Fry regards the question as beset with difficulties, which can only be met by intelligent attention to details, which are constantly varying, and he declares he has 'neither seen nor heard of a silo which perfectly fulfils the necessary conditions'; he also declares that 'even if such a silo were in existence, it would not be possible to ensure results always good alike.' This is, of course, obvious when we reflect that the result depends on the quality of the grass or other raw material used for the purpose, on the amount of moisture it contains, on the degree of maturity at which it has arrived when it is cut, on the peculiarities of its growth and structure, on the weather at the time, and on other conditions which provide plenty of scope for the exercise of skill and judgment.

Mr. Fry is more cautious than some writers have been on this topic, when he says that the silo does not render the ensilage absolutely independent of weather and other circumstances; and in giving this timely warning to farmers who may haply have been carried away by what they have read elsewhere, he is not only doing the best service to ensilage as a system, but is lessening the volume and risk of cruel disappointment. At the same time, the difficulties spoken of may be overcome by careful and intelligent attention, and success is within reach of every man who will take the necessary pains. These points are definitely laid down, viz. (1) A perfect silo must be air-tight, water-tight, and 'heat-tight.' (2) The forage put into the silo must not contain more than 75 per cent of moisture. (3) The temperature of the silage must rise above 122 Fahr., or it will be sour. These points are clear enough, but they require the exercise of care and judgment. To a man whose mind has seized principles of the system, there is no more difficulty, all things considered, than in hay-making; but even in hay-making, we see a great deal of non-success, which is the result not of bad weather only, but also of carelessness and even ignorance on the part of farmers, in so apparently simple a process.

A silo must have even and perpendicular sides, in order that the weighted covering may follow the silage closely as it sinks. The form of it, however, may be round, instead of square or oblong, but in any case the inner surface must be smooth, straight, and perpendicular. Stone or brick walls are plastered with cement; concrete walls may, perhaps, be made to do without a plastering of cement, and in this event they are probably the best walls that can be used for a silo. It is obvious that the walls, whatever material they may be built of, must be strong enough to resist any pressure that may come against them from the inside; this pressure, however, is not very considerable. There is no need for a drain or other outlet for moisture at the bottom of the silo. If a doorway is left in the wall for convenience of emptying the silo, it should be made perfectly air-tight before the silage is put in. This may be done without much difficulty, providing the door is well made and strong, the framework properly constructed, and the packing even and sufficient. Perhaps the best way is to break up the doorway when the silo is empty, plastering it inside with cement, like the rest of the inner surface of the silo. The roof of the silo must be high enough above the square to admit of having the ensilage trodden evenly around by the walls and close up to them.

The silage is usually covered with boards or planks and weighted above. The weighting should not be less than 100 lbs. to the square foot, on a silo 15 to 20 feet deep. A shallower silo would require similar weighting, so that it is advisable, on the

ground of economy in weighting, to have it a good depth. The covering of planks admits of just so much surface being uncovered at a time as may be advisable, the planks being laid down parallel to the side of the silo, and from which the silo is emptied. An oblong silo appears to be preferable to a round or a square one, because it exposes a shorter face when the silage is being cut away; it has, however, the disadvantage of requiring additional walling and plastering. For instance, a silo 30 feet square inside, superficial measurement, would make two oblong silos of 30 feet by 14 feet 6 inches, if the partition wall were a foot in thickness. It is considered that two such silos would afford greater advantages in respect of filling and emptying than one of double the size. The partition wall, however, unless very strongly built, would be a source of weakness all the time, and it would be subject to certain lateral pressure when the first of two silos was being filled, and when one of them had been emptied. But it may be made strong enough for anything that would come against it, and once made, it is there for good. It would, of course, entail some additional plastering with cement, equal, indeed, to 50 per cent of the whole outer wall surface of the silo.

It is considered essential to cut the crop for ensilage at the stage which is thought fit when cutting it for hay. This is when it has reached maturity, and is about to ripen. 'Sweet ensilage,' says Mr. Fry, 'bears about the same relationship to the green crop from which it is produced, as ripe fruit does from green, and this is the reason why the green crop must be cut at the stage above mentioned—a stage which favours the ripening of the silage in the silo. At this, too, the green crop contains about the right proportion of moisture, viz., 72 per cent. In cases where early crops of rye, oats or clover, are cut to make room for other crops to come on, it will be advisable to let the crop lie cut on the ground for a day or so until the moisture which is excessive for silo preservation has evaporated. Green rye is deceptive in this respect, and great care has to be taken that it contains only the right proportion of moisture. Great stress, indeed, is laid on this point, and as I believe, with all sufficient reason. Crops containing more than 75 per cent of water are unsuitable for preservation in a silo until the proportion has been reduced; and Mr. Fry's experiments on this point dispose of the absurd claim made by certain enthusiasts that grass can be cut in any sort of weather for storing in silos, and that rain water in it is a matter of no consequence. Mr. Fry says that in no case has he obtained a good result from fodder, which has been so wet, that moisture has been pressed out of it in the silo. Believing that when 75 per cent. of moisture is not exceeded in the silage, no appreciable quantity of moisture will be pressed out of it, he says there 'should be no drain or other outlet for moisture at the bottom.'

The drier the fodder, the greater should be the compression of it in the silo, and the earlier a silo will be opened, the greater weight should be put on it as well. Before a silo is filled a second or any subsequent time, the walls and floor should be carefully washed down with a weak solution of carbolic acid, last of all, in order to rid it of fungi and spores that may adhere in places; this, in fact, is an important matter. The objects aimed at in a silo are to induce a temperature of over 122 Fahr. in every part of it, and to prevent the access of air to the silage after it has been exposed to this temperature. With an ordinary crop of meadow grass, it will be advisable to fill the silo at a slower rate than with green rye, oats, or other bulky crops, in order that the temperature which the mass attains may be diffused pretty equally through the place. About 4 feet added each day appears to be the rate suited to grass until the silo is full, after which it will require filling up at times as it sinks. The temperature of the silo at different depths may easily be ascertained by using a length of gas-pipe to which at one end a steel point has been welded, and which is perforated there by a number of small holes. This may be pushed down to the desired depth, and when it has been in for ten minutes or so, a thermometer lowered down the inside of it by a string will, in a few minutes' time, and on being withdrawn, indicate the temperature of the silage at the spot to which the pipe has penetrated. A bit of cotton wool in the bottom end of the pipe will lessen the risk of breaking the thermometer.

The temperature at from 4 to 6 feet from the surface should reach at least 122 Fahr. in two or three days after filling. Even if it reach 140 to 160 degs., so much the better; if it do not reach the desired height, this may be regarded as proof either that the stuff is too wet or that the filling and compression have been going on too quickly. As there is no fear that spontaneous combustion will ensue, the temperature may be ascertained closely enough by the aid of an iron rod simply, thrusting it down into the mass and trying its heat by hand when it is withdrawn. Ordinary British crops do not need chaffing for a silo, but they should be evenly spread in it, and well trodden down, specially near the walls.

Our author, who has produced a valuable book, advises farmers to try ensilage at first on a small scale, until they have learnt to make it properly; then they may extend the system as much or as little as they think proper. The crops ensiled should be of good quality, and in a proper state of maturity, for young, succulent, pliable herbage will produce silage of a quality unsuited for the production of good milk. The system of ensilage adds one more resource to the farmer, but it is not calculated to supersede either hay-making or root-growing in any very marked degree. It is obvious that while hay must contain only some 15 per cent. of moisture, and silage may contain 75 per cent., the crop preserved is more easily digestible in the one case than in the other, and silage may be made when hay would be spoiled by the weather. It is easy enough to make good hay in fine weather, and silage can be made when it would hardly be considered fine, though, as it would seem, wet weather is suitable for neither process, though less so for hay-making than for ensilage.—*North British Agriculturist*.

THE INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA:—SATURDAY, AUGUST 22, 1885.

[No. 34.]

Health, Crop and Weather Report.

FOR THE WEEK ENDING 12TH AUGUST 1885.

General Remarks.—Rain has fallen in all districts in the Madras Presidency, with the exception of Bellary, where it is much wanted for the dry crops, which are suffering. In Madura prospects continue unsatisfactory, and more rain is wanted in Ganjam, Kistna, Coimbatore, Tanjore, and Malabar. In Mysore prospects are uncertain in consequence of the deficient rainfall. Dry crops recently sown are reported to be withering in many places, and agricultural operations have been retarded. In Coorg seasonable weather prevails, and prospects are good.

Slight rain has fallen generally throughout the Bombay Presidency, but more is wanted in parts of Sholapore, Ahmednugger, Bijapore, Nasik, Khandesh, and Dharwar. Young crops are withering in some districts, and have in some places been injured by insects. In the Berars slight rain has fallen, and crops are promising. In the Nizam's territories rain is much needed for the standing *khari* crop. In the Central India and Rajpootana States good rain has fallen generally, and agricultural prospects are satisfactory.

In the North-Western Provinces and Oudh heavy rain has injured the crops in some places, and a break is now much needed. The condition of the crops is, however, generally very favourable. Rain has fallen in most districts in the Punjab. *Khari* sowings have nearly been completed, and prospects are on the whole good. In the Central Provinces the weather is seasonable, and crop prospects are favourable. Transplanting and weeding continue in most districts.

In Bengal rain has been general, but in parts of the Presidency Division more is needed. Some damage has been caused to crops by floods in the Midnapore District and the Bhagulpore Division, but otherwise prospects are generally favourable. The *bhadoi* harvest is yielding a good average outturn. In Assam rainy weather prevails, and the transplanting of *sal* rice is in progress. Tea promises well. Seasonable rain has fallen in all districts in British Burmah, and prospects are good.

The public health is generally fair in most provinces. Prices are fluctuating in the Punjab, but elsewhere they are generally steady. In Bengal the price of rice continues high.

Madras.—General prospects fair, improved in Bellary and Anantapore; in Madura reported to be discouraging.

Bombay.—Slight rain in most districts; more wanted in parts of Sholapore, Ahmednugger, Poona, Bijapore, Nasik, Khandesh, and Dharwar. Young crops withering in parts of Sholapore, Khandesh, Bijapore, and Tanna, and injured by insects in parts of Hyderabad, Upper Sind Frontier, and Bijapore; fodder scarce in parts of Khandesh, Sholapore, Nasik, Ahmednugger, Poona, Bijapore, and Belgaum. Cholera in parts of eighteen, fever and cattle-disease in parts of nine, and small-pox in parts of four districts.

Bengal.—General rain over the whole province; more rain wanted in parts of Presidency division. Floods in Midnapore and the Bhagulpore division have done some damage to the crops. Prospects continue generally favourable. Transplanting proceeding well in Central and Eastern Bengal; *bhadoi* harvest in yielding a good average outturn. Price of rice continues high. Public health generally fair.

N.W. Provinces and Oudh.—Heavy rain has fallen throughout the provinces, and caused injury to the crops in some districts; a break is much required. Prices are fairly steady, and public health good; cases of cholera reported from Gorukhpore, Allahabad, and Agra.

Central India.—Rain has fallen in most districts. Health generally good. *Khari* sowings nearly completed; prospects on the whole good, but more rain is wanted. Prices stationary in some, and rising in other districts.

Central Provinces.—Weather seasonable. Crop prospects favourable; transplanting and weeding continue. Cholera in Raipore and fever in a few places. Prices steady.

British Burmah.—Cholera severe in one district, slight in seven districts, elsewhere public health good; cattle-disease severe in one district, slight in five districts, elsewhere health of cattle good. Ploughing, sowing, and transplanting progressing. Rain seasonable in all districts, except in Proma, where more rain is required, and in Amherst where

they have been very heavy, and the crops have been slightly damaged by floods.

Assam.—Weather seasonable. Transplanting of *sal* rice continues; prospects of tea good. District healthy.

Mysore and Coorg.—Coffee and cardamom crops in good condition. Prices of food-grains stationary. Prospects of season and public health good.

Berar and Hyderabad.—Rain much needed for standing *khari* crops. Cholera still prevails in the city and suburbs has broken out at Secera on railway line; general health of people fair. Prices—Wheat 14½, coarse rice 12½, white *juari* 19½, yellow *juari* 22½, and *ter* 15½ *seers* per current sicca rupee.

Central India States.—Continuous rain. *Juari* crop much damaged. Health good; slight cholera at Bhopal.

Rajpootana.—Tanks and wells low. Crop prospects excellent up to date. Health good. Prices cheap. Weather fine, passing clouds and mist.

Nepal.—Rainfall sufficient. Prospects good. Cholera decreasing everywhere.

Letters to the Editor.

THE AGRICULTURAL SOCIETY OF INDIA.

SIR,—This Society is one of the few institutions of the kind that we have for carrying out agricultural and horticultural improvements in this country, and it should therefore be largely patronised by all classes, both native and European. But it is a painful fact that the Society is not as strongly supported as it should be. Of course, there is no excuse for the rich and prosperous of our country withholding such support, but so far as the middle classes are concerned, I must say that the rate of subscription fixed by the Society is very high. If this was reduced, I am confident it would receive better patronage and support from the public than it does at present, without suffering any pecuniary loss. Of the various advantages the Society holds out to its members, the Mofussil residents may expect to avail themselves of only two. They have no opportunity of either using the Society's library at the Metcalfe Hall, or voting at their ordinary meetings. Moreover, most of those of the same class as myself would not benefit by the Society's concession of a box of plants gratis every year (itself worth a large sum), or purchasing plants from the Society's gardens at members' rates. Take my personal case, for instance: I am a Government servant, and am liable to be transferred at any moment. I keep a garden on another's ground, and therefore have no incentive to plant anything beyond what I may fairly expect to reap the fruits of. At the same time, I wish to be a member of the Society. The only advantages I expect to reap from the Society are—(1) the packets of seeds and (2) the journals it supplies to the members periodically. It is therefore neither fair nor just, and is certainly very hard, that I should be expected to pay at the full rate of subscription payable by Calcutta members who have all the advantages of the Society. I therefore beg leave to suggest that the Society alter its rates for enrolment of members, and reduce its rate of subscription so as to bring it within the reach of all classes. There are already three classes of members, viz.—(1) honorary members, who reap all the advantages of the Society without paying for them; (2) corresponding members who are paid for the articles they contribute to the Society's journal; and (3) ordinary members who pay Rs. 32 annually as subscription, and an admission fee of Rs. 8. Why not add a fourth class of members, entitling them only to the seeds and journals on half the subscription paid by ordinary members? To render the Society more popular and largely patronised, I

would suggest that the subscription for ordinary members be reduced to Rs. 20, and for infusill members of the 4th class, now proposed by me, to half the subscription payable by ordinary members.

AN AMATEUR GARDENER.

ENSILAGE vs. GREEN FODDER.

TO THE EDITOR.

SIR,—I trust you will allow me to make some comments on your article, "Ensilage vs. Green Fodder." You say you are convinced that silage properly prepared possesses qualities superior to ordinary fodder in its green state, but can you suggest any source from which fodder enclosed in a dark pit can obtain these superior qualities. You offer to quote authorities in support of this view, but the only one you mention is General Wilkinson, the accuracy of whose statements you say you have no reason to doubt. Now let me ask, with all due deference, what reason you have for believing in their accuracy? The statements are themselves, to quote your own words, "almost too much for one's credulity," and as such no sensible man would believe them, unless he were sure that the General had not been misled by deceptive appearances or some other cause. First, as regards weight, the facts on which the General relies are that two cows which were fed on ensilage (amount not stated) for 28 days after they had been kept for a similar time on grass (amount not stated) increased in weight 39 pounds. Now unless we know the amounts of grass and ensilage given, it is impossible to decide in favour of either. Again, what practical man would think of using cows giving milk when trying an experiment to show that one kind of food is more nutritious than another? I believe that some Commissariat bullocks were fed on the General's ensilage. What is the opinion of the officers in charge of these bullocks as to the value of ensilage vs. green fodder? Now, as to the yield of milk, the fact that amounts of food are not given, vitiates these experiments. Indeed, the General himself seems to disbelieve in the accuracy of this experiment, for in his letter to Government, dated 28th May 1885, page 14, he says: "With this universal (but variable) daily decrease of yield, it has been found impossible to tabulate the advantage gained by the use of silage, for increasing the yield of milk." Lastly, as to the quality of the milk, the General starts with the misconception that the milk of cows get poorer as their calves get older, but the reverse is the case, the quality improving as the quantity decreases. Then he tests for cream with a milk-tester only. Without a creamometer such experiments are valueless; for skim milk properly adulterated with water will have the same specific gravity as milk rich in cream. I could give other instances to show that experiments made by General Wilkinson should be received with caution; and certainly where the results are almost incredible, and opposed to the views of all scientific men, they ought not to be treated as demonstrated facts.

I still hold that the superiority of ensilage has not been abundantly proved, and as long as certain butchers and dairy men in England object to receive the produce of cattle fed on ensilage, I think your readers will agree in thinking that practical men are not in this case opposed to science.

Apologizing for the length of this letter, I am Yours, &c.,

D. ALLEN.

Camp Arrah, August 10, 1885.

NOTE.—We hope to take up the subject in continuation in our next.
—ED.—I. A.

TOBACCO CURING.

TO THE EDITOR.

SIR,—I learn that tobacco of very superior quality is manufactured at Poonah. I therefore beg to suggest that two students should be nominated from each division by the Commissioner to learn the art of curing tobacco, to be apprenticed there on the condition that none shall be selected who, or whose parents do not own a cultivation of more than 20 biggahs, and that the selected students should get 12 Rupees a month for two years if they have passed Minor Scholarship, Vernacular Scholarship, or Entrance examinations; and 8 Rupees if they have no such qualification.

S. DATTA,
Mowbhunj.

Editorial Notes.

A GERMAN paper says that forty parts of paper pulp, ten parts of water, one part of gelatine, and one part of bichromate of potash, with ten parts of phosphorescent powder, will make a paper which will shine in the dark, and which will be suitable for labels, signs, &c.

**

THE quantity of Tea exported from China and Japan to Great Britain from the opening of the season to the 16th of July was 59,103,131lbs., as compared with 64,128,479lbs. exported in the corresponding period of last year. The exports to the United States and Canada during the same period were 14,538,657lbs. as against 16,812,468lbs.

**

WE believe that many of our readers are not aware of the many uses to which coconut fibre can be brought. Among others, it has been found most useful in planting coffee and tea seedlings. A correspondent, who has tried the experiment, says that not only is the fibre a very good protection for the tender rootlets of these plants, but that it acts as a capital manure. Tea and Coffee planters should take note of this.

**

WE are informed that a horticulture show, which was held at the Lail Bagh at Bangalore in the afternoon of the 13th instant, was a great success. It is stated that the flowers and fruits exhibited were the best that have been shewn for years past. This speaks much for the enterprise of the management of this garden, and of the exhibitors, when it is remembered that a severe drought and water-famine have been experienced at Bangalore this year.

**

THE total receipts from the four sales of Bengal opium and four months' duty on opium exported from Bombay were Rs. 2,77,35,105, which was Rs. 5,85,105 better than the estimate. The receipts from Bengal opium were for the first time for some years worse than the estimate by Rs. 4,32,095, whilst those from Bombay were Rs. 10,17,200 above the estimate. The great deficiency in the Bengal receipts occurred at the July sale, when they were no less than Rs. 1,17,045 below the estimate.

**

THE total exports of tea from Calcutta from the 1st of May to the 31st of July amount to 9,962,193lbs. the quantity for the two preceding years being 7,516,488lbs. and 6,317,792lbs. respectively. In July, as compared with those of July, 1884, the exports to England showed an increase of 178,883lbs. while those to Australia advanced 7,280lbs. and those to America 2,213lbs. The improvement has extended to the Ceylon trade, which has advanced to the extent of nearly two million pounds in the past three years.

**

WE learn that the Government of India has received a report from Dr. Hallan on the results of his visit to Dr. Pasteur's Laboratory in Paris, and his observations on the method of cattle vaccination pursued by the French Professor. It has been suggested that some of the Veterinary Officers sent out to India should undergo a special course of training in institutions devoted to the study and culture of disease germs; and there is a proposal for the establishment of a laboratory in connection with the Lahore Veterinary School.

**

THE latest London advices concerning Tea are for the week ending 23rd July, when Messrs. LLOYD and CARTER write as follows:—

Further arrivals of new season's tea have been offered during the week, and have sold generally at a decline on previous quotations.

Thin Darjeelings are 1s. to 2s. easier, but good Teas of all grades from this district have been well competed for. Cachars and Assams generally are poor, and low prices have been realized.

Rates ruling for old teas are unchanged, but the demand is not brisk, country trade being unusually quiet.

In another column will be found three reports on silos in Burmah, from which it would appear that this method of storing fodder has not been productive of satisfactory results. As far as we can make out, its disadvantages lie on the side of expense; but, as the papers are descriptive enough, there seems no necessity for noticing them at length here. Suffice to say that, for the present, no more such experiments will be undertaken at the public expense.

Elsewhere will be found an account of an influential meeting held at Chinsurah on the 18th instant, when it was decided to hold an exhibition of agricultural produce and implements next cold season. It cannot be doubted that such exhibitions are calculated to have the best possible effects, and much credit is due to the public-spirited zemindars and residents of Hooghly for their efforts in this direction. We hope they will receive all the support their energy deserves, and that they will be able to carry their scheme to a successful issue. We shall be glad to hear, from time to time, of the progress of the project.

THE *Builder*, referring to the rotting of timber, makes the following remark, which should be noted:—"The *Merulius lacrymans* is the common wood fungus that destroys nine-tenths of the wood with which we are acquainted. The reason of its being common to new buildings and not to old, is that moisture, one of the constituents of its existence, is more present in new green buildings than in old dry seasoned ones. The two prime conditions of its existence are moisture and heat; if moisture is present without heat it will not grow, and hence its depredations in the winter time are unknown. If heat is present without moisture, it will not grow, and hence ventilation for the passage of a current of dry air will prove fatal to its existence.

We regret to learn that the prospects of a harvest in Southern Russia are unfavourable. A South Russian paper says:—"The heat is at present almost unbearable. For months not a drop of rain has fallen. Everything looks yellow and scorched, and the cattle can hardly find pasturage. Hay is enormously dear, and the price of cattle is already rising. At the end of May it was so hot that all hope of a good harvest had to be abandoned. Then there was a sudden change, and extreme heat changed for a time to extreme cold. At present the heat is again very great; all vegetation is burnt and dried up, and the woods or gardens which have not been altogether spoiled by the heat are devastated by innumerable caterpillars." This applies primarily to the Crimea, but it is to be feared it is true of a larger area.

Kuhlows, writing on the fruit harvest in the Rhine District, says:—"The flowering of the vine is now over, and it has, on the whole, been very satisfactory, though there was towards the end unfavourable weather. The young plants are coming on capitally at present. The old vines are also progressing well, so that the position of affairs gives general satisfaction. No noteworthy damage has been done in the fields or vineyards, but the cherry harvest has been injured. On the 3rd instant, 11 and 12 Pf. was paid per pound, but in consequence of the wetness the cherries have in great part burst, and now only 7, 8, and 9 Pf. is paid. The walnut trees are well laden with fruit, but no little injury has been done to it. Of pears and all kinds of stone fruits there is a large quantity. On the whole, there is no need to be discontented with the harvest prospects."

The following is a summary of the harvest crop in Germany according to a German contemporary:—"Official reports are published concerning the prospects of the harvest throughout the whole country. Wheat as well as summer fruits and especially hood crops have more or less improved everywhere, but rye did not gain by the late rains, as the time of its growth was passed. The chief producing provinces, Prussia, Posen, Pomerania, Silesia, and Brandenburg, complain—particularly in light soils—of the small crops, and as these possess the largest

area of rye the heavier crops elsewhere can but poorly compensate. Hanover, Hesse, Nassau, Westphalia, and Rhineland report a good yield, and in Saxony and Schleswig-Holstein a yield of rye below consumption is apprehended. The rye harvest on the whole promises to be under the average. The first rye of the harvest was brought to market in Berlin a day or two ago, being bought at 162 Marks per 1,000 kg. The quality was very good."

The following, which we extract from the *Farmers' Review*, is not cheerful reading:—"Prof. Riley, Entomologist for the Department of Agriculture, announces that this year we shall have two distinct species of locusts, the seventeen and seven year locusts. It has been two hundred years since these two kinds have appeared in the same season. Neither are destructive to crops; their chief injury is to trees by depositing their eggs in the tender twigs of the new growth, which cause the portion beyond the egg deposit to die. The Hessian fly and chinch bug is reported as at work this spring in the wheat in those districts where it was present last fall. These are the new crop hatched from the eggs deposited on the plant last fall. There is no remedy for them now or nothing which can be done to prevent their damage to the wheat. Grasshoppers are already reported at work in Texas, and the bark louse is present in unusual numbers upon fruit and shade trees in wide districts of the country. Altogether we are likely to have a buggy season."

It will surprise tobacco smokers to know that, according to Mr. Crowe, British Consul in Cuba, cigars suited to the taste of the British smoker, are very difficult to obtain in Havannah. Mr. Crowe allows that there is plenty of "dark powerful tobacco" of fine quality, at moderate, though by no means low, rates. But if a smoker desires a light leaf, with aroma, such as the "educated palates of an Englishman" seek, he must be prepared to pay for it. Only about ten per cent. of the tobacco harvest of Cuba can be classed as of this quality; and, apart from the cost of the raw material, the best makers of the best cigars obtain wages which alone would render their handiwork of value. As much as 40 dollars in gold are paid in skilled labourers for turning out 1,000 "first-class goods." This means that a cigar of this grade costs two pence for the mere rolling, apart from the boxing, the price of the tobacco, the freight, the Custom-house duty, the interest on the capital expended, or the profits of the two or three middlemen before it gets between the lips of the European consumer.

The statistics of the home paper trade, for the month of May 1885, are as follows:—The exports of stationery for the month of May this year amounted in value to only £84,520, as compared with £71,860 in the corresponding month of last year, and during the five months the value was £316,569, against £332,608 in the like period of 1884. The exports of paper for May amounted to 70,057 cwt., value at £138,690, against 61,718 cwt., valued at £132,161 in May 1884. The export figures for the first five months of the year show that the quantity of paper exported during that period has been 338,393 cwt., valued at £699,838, as compared with 303,145 cwt., valued at £556,459 in 1884. The sum of £500,000 out of the current year's exports represents the value of writing and printing paper and envelopes which have been shipped to Colonial and Continental ports. The imports for May amount to 107,165 cwt., valued at £104,784, against 119,252 cwt., valued at £112,597, in May 1884. In the five months the respective totals are 534,656 cwt., valued at £506,036 in 1885, and 581,498 cwt., valued at £556,164 in 1884. In each case allowance is made for the re-exports of the foreign-made product.

The following, which we take from the *Lumber World*, illustrates a curious superstition which prevailed among the early American settlers:—Abraham Reed, a farmer, living in Beaver township, Pa., cut down a large oak tree on his farm, and in cutting it up he found, imbedded in the trunk, seven or eight feet from the ground, a small glass bottle, and what

had the appearance of a lock of hair. The bottle had been inserted in a hole in the tree made by an auger, then a pine plug was driven into the hole over the bottle, the hair also being held in the hole by the plug. The bottle was corked, and contained a colourless liquid. Over the plug had grown six solid rings of wood, besides a thick bark. There was a superstition among the early settlers, and it is held by many of their descendants, that asthma and other affections could be cured by the victim standing against the tree, and having a lock of his hair plugged in it while the hair was still attached to his head. It must then be cut off close to his head, and the afflicted person must walk away without looking at it, or ever passing by the tree again. While the use of a bottle was not included in this treatment, it is believed that the one with the hair discovered in the heart of the oak tree was put there in the early days of the settlement by some believer in the superstition to cure an ailment of some kind.

We see that the Royal Commission of the Indian and Colonial Exhibition has decided to provide accommodation at this Exhibition for paintings, water-colours, and drawings by artists and amateurs resident in India, and will defray the cost of packing and freight from Bombay to London of selections that, after inspection at Bombay, may be deemed of sufficient interest or merit to send. The paintings and drawings must be neither framed nor glazed, as it is intended to economise the cost of packing and freight as much as possible. The latest date for receiving paintings and drawings will be November 30, and they must be sent to Messrs. King, King & Co., Bombay, with particulars and name of exhibitor, subject of picture, and value. Mr. J. D. Griffiths, Superintendent, School of Art, Bombay, will inspect all paintings, water-colours, and drawings despatched to the firm. The Royal Commission does not undertake any risk, and exhibitors will have to make their own arrangements as to insurance. The framing will be done in London by Messrs. Henry S. King & Co., and full particulars of cost, &c., can be obtained from Messrs. King, King & Co., Bombay and Messrs. King, Hamilton & Co., Calcutta.

AMERICA is rousing herself in regard to her silk industry: for, from a paragraph in the last number of the *Farmers' Review* to hand, we find that Mr. C. V. Riley, Entomologist for the Department of Agriculture, is sending out a circular for the information of silk culturists, stating that during the coming summer the Department of Agriculture will purchase such quantities of silkworm eggs as may be deemed necessary for the proposed distribution to be made in 1886. So far as practicable, the eggs will be purchased of American producers, but under certain precautions which are as follows:—Eggs of improved races only (preferably of the French or Italian yellow races) will be bought; producers should send one or two samples of pierced cocoons with eggs; the egg-producing worms must be in perfect health; there must be no indication of the disease called *flacheri*; if the worms have all the indications of health until the spinning period, then the cocoons may be used for the production of eggs. These eggs will be paid for at the rate of \$2.50 per ounce of 25 grams (about 6.7 of an ounce avoirdupois), and those desiring to raise eggs for the purpose will receive full instructions from the circular No. 9 which may be had on application to the Entomologist, United States Department of Agriculture Washington, D. C. Silk culturists are advised not to attempt the production of eggs, unless they are adepts at the industry, and have had at least one season's experience. They should also send a sample and statement of the quantity offered for sale.

THE accounts from the indigo districts in Bengal still continue unfavourable, and the plant remains small and backward through too much rain and absence of sunshine. This is especially the case in Jessore and Midnapore, and the outturn in both these districts is expected to be small. In Krishnagur matters are a little better, and in Moorsheadabad the prospects are fair, and produce has been good. But even in these two districts more fine weather is required to bring on

the plant. Purneah was at one time doing fairly well, but latterly prospects have been seriously affected by the rising of the river, which has swamped the plant at some factories. The accounts from Behar are on the whole rather better, as the weather has been generally favourable, but accounts from the different factories vary considerably, the result of the vat produce being fairly good, whilst the biga produce is small. *Moorthun nahi* will close about the end of the month, but though the prospects of the *khoonties* has been somewhat improved by the late rain, there is not much chance of a good return, owing to the lateness of the season. Manufacture is just commencing in the Benares district, where in some parts there has been too much rain, and the area under cultivation is less than that of last year. Throughout the North-West generally, and especially in the Alighur and Balandshahr districts, considerable damage has been done by the late heavy rain and floods, and the outturn generally will be less than was anticipated.

THE present number of the "Records of the Geological Survey of India," being Vol. XVIII, Part 3, for 1885, maintains the reputation of that periodical, both as a valuable record of work done in India, and as an interesting expositor of geology and the kindred sciences generally. The contents of the August number are of an unusually varied character, and to most persons will possess special interest in consequence of the two papers on earthquakes. Mr. R. D. OLDHAM leads off with 11 pages of "Notes on the Geology of the Andaman Islands," to which is prefixed a coloured geological map. These islands consist mainly of eocene and miocene rocks, with intrusive volcanic rocks, mostly diorite and serpentine, occurring here and there. Mr. R. LYDEKKER follows next with a brief palaeontological Note, the chief interest of which lies in his announcement of the identification of two fossils in the British Museum, formerly discovered by Dr. FALCONER, which belong of right to the Indian Museum, and which are accordingly to be transferred to the latter institution. Then follow two papers by Mr. H. B. MEDLICOTT, the head of the Survey, written in his admirably lucid and vigorous style: the first on "Percolation as affected by currents," and the second on "The Pirithalla and Chandpur Meteorites." Next comes a paper on "Coal and Oilwells in Burmah," by Mr. R. ROBERTS; followed by another on "Antimony Deposits in Moumela," by Mr. W. R. CHURCH. Two papers on the Cashmere and Calcutta Earthquakes, by Mr. JONES and by Mr. MEDLICOTT, respectively, close this interesting number of the records.

OUR readers will recollect that some little time back, we noticed the cultivation of the mahogany tree in the Madras Presidency, and that the Government had made an application to the Governor of Jamaica for a fresh supply of seeds. We now learn that the Governor of Jamaica has informed the Madras Government that a supply of seeds had been despatched on the 10th May last to the Royal Gardens, Kew, for transmission in the usual manner to the Government of India and the several Presidencies. We fail to see the expediency of this round-about course, thus subjecting the seeds to two sea voyages. It has been found by experience that a sea voyage affects the vitality of mahogany seeds; and if it is intended to obtain satisfactory results from sowing of these imported seeds, we fear disappointment only may be expected under the circumstances. Why the seeds could not, in the first instance, be sent direct to India, instead of being sent all the way to England, and then back again to India, is what puzzles us. There might, we think, in this instance at least, have been a departure from red-tapeism with advantage. The seeds left Jamaica on the 10th May last, and the Madras Government "Order" on the subject is dated 16th July. There is no mention of the seeds having been received up to that date, and they will perhaps not be received for two or three months to come, when the season for sowing may have passed away.

WE learn from a contemporary that the Assistant Director of Agriculture in Burmah, about this time last year, in reply to some inquiries from the Military Department with reference to the fodder supplies of Burmah, recommended the cultivation of crab grass. He has just published a report on the system of

cultivation then recommended, which was adopted this season at the Kyauktan farm, and gave an output of nine tons per acre for the first cutting in July, whilst another cutting can be made in October. The first cutting can either be used as green fodder or preserved in a silo, whilst the October cutting can also be cured as dry hay. The hay that was made last October kept in excellent condition until the rains commenced this year. This grass is but little valued in India, whilst in America it is much valued as a hay crop, and is still more valuable in Burmah, as it gives twice the amount of grain and also an extra cutting. In Burmah it grows to the height of about three feet, and horses and cattle of every kind eat it with great relish, and will remain in good condition if fed on it without any other grain. Its cultivation appears to be very simple, as the land only requires to be ploughed twice at the beginning of the rains with a turn plough, and then harrowed twice with a triangular harrow, when the grass will germinate of its own accord.

.

In another column we print a few practical suggestions from "An Amateur Gardener," to which we direct the attention of the Agri-Horticultural Society of India. We cannot help thinking that the rate of subscription fixed by the Society for ordinary members is rather high. We believe that the present rates were fixed many years ago when horticulture was in its infancy so far as India is concerned, and the conditions for importing European and American seeds were different. Many changes have taken place since then; what at that time cost 5 rupees, can now be had for very nearly half that price. Again, it must be remembered that very keen competition exists between the several seedsmen, and there are at present greater facilities offered for the importation of seeds and plants than presented themselves, say 15 or 20 years ago. It is therefore only reasonable that the Agri-Horticultural Society should keep 'touch' with the exigencies of the times. We have no doubt that, were the Society to reduce its rates of subscription, there would be a corresponding increase in the number of subscribers; and by the rule of "small profit and quick returns," there is every reason to believe that, whatever loss it might suffer at the commencement, would be amply recouped by a large addition of members, and an increased popularity. Much competition may soon be expected in the supply of English and American flower and vegetable seeds in India. Some of the largest seedsmen in England and the Continent have established agencies here for the sale of their seeds, and only recently David Landreth and Sons of Philadelphia have opened an agency for their seeds in this city. It will naturally follow that if better value can be had for their money at these agencies, people will not pay Rs. 32 annually, with an entrance fee of Rs. 8, to become members of the Agri-Horticultural Society of India, which may lose by this means many of its ordinary members. We are therefore inclined to think that, for the reasons advanced by our correspondent, the reduction in the rates of subscription suggested by him might with advantage be adopted. The suggestion for the creation of a fourth class of subscribers, seems a good one, and we commend it to the favourable consideration of the Society.

.

The following extraordinary *canard* appears in the *Englishman*, under the head of "Notes and Queries":—

It was formerly the case that the journal known as the *Indian Agriculturist* was maintained by a Government subsidy of Rs. 60,000 per annum. Government subscribed for 5,000 copies. Can any one tell me if this subsidy is continued? Or did it fall among the first fruits of retrenchment? It will be news to the public that such a journal exists; and it will be interesting to know whether Government is wasting public money in this way when it is grasping at the petty cash balances of Municipal Boards and Road Cess Committees.

The *Indian Agriculturist* receives no subsidy whatever from the Government. Many years ago the journal was started by ourselves as a focus in which might be gathered together whatever essays, or notices, of any interest or importance, on the ordinary agriculture of the country, might appear in the various local *Gazettes of India* or in our newspapers. It was originally started as the *Agricultural Gazette of India* in 1869. Upon its unwise suppression in 1875 by Lord NORTHBROOK, an

effort was made by Sir RICHARD TEMPLE to substitute an official *Statistical Reporter* in its room. This publication was brought out by the Bengal Secretariat, but proved to be so costly, and was moreover so ill-conceived, that it was abandoned after a year or two's publication, during which the cost of it ran up we believe to more than Rs. 1,00,000. The idea of the *Indian Agriculturist* is unique, and is most valuable, although it has never been appreciated properly by the Government. The attention given by Mr. KNIGHT to the 'settlement reports' of the country, early convinced him of the need there was of some publication in which should be recorded for reference, every important experiment, or essay, upon improving the *ordinary agriculture of the country*. Lord Mayo saw the desirableness of such a record, but none of his successors have taken any interest therein. We have continued its publication from a conviction of the need of such a journal, and in the hope that at some time or other, its importance and its value would be appreciated. At this moment, the 16 or 17 volumes which have been produced since the year 1869, are of unique value. As to this nonsense in the *Englishman* about a subsidy, the aggregate subscriptions of all the various Governments of the country are so trifling, that we continue the publication only from a sense of its value as a record. Had the Government but spent upon it one-twentieth part of the money it squandered upon its own *Statistical Reporter*, we should long since have made the paper a semi-official gazette of the highest value.

.

The following notes, which we take from a contemporary, sums up the results of the measures taken by the Western Presidency to hit upon the most economical, and at the same time the best method of raising water for irrigation purposes:—The Bombay Government have recently published some very practical and interesting papers on the subject of cheapening the construction of wells, and on the most economical method of raising water for irrigation. Leaving out of the question the possibilities of the Artesian well, the conclusions arrived at in the papers now before us are that in the Bombay Presidency there are "no peculiar difficulties calling for a science in any shape to overcome, and that with regard to economy in construction the cultivators are conversant with, and do make use of, when necessary, a very cheap system of well-making which it is impossible to improve upon." As to the best means of raising water for irrigation, after a comparison of several methods, native and European, a verdict is given in favour of the old leather-bag contrivance known as the *mote*. It is simple, easily repaired, brings up a good supply of water, and only requires one man and a pair of bullocks. The more intricate Persian wheel never raises anything like the quantity of water it ought to do, when worked by bullock-power, and it is not considered a sufficiently perfect machine to be placed in serious competition economically with a *mote*. As regard the other methods, the Burgess Bucket lift, which may be described as a perfect Persian wheel, requires a very strong pair of animals to work it; and if the necessary charges are taken into account, there would be a final deficit of Rs. 79 at the end of the year. Hartford's windmill, or Californian pump, worked under the most favourable circumstances, showed a deficit of Rs. 57 on the year's operations. Lastly, a comparison is made with a steam pump, used in Baroda for raising water for the public park. The machine cost Rs. 5,000. It is found that the fuel and working expense of this steam pump, without including the usual charges for interest, &c., made the cost of raising water by it exactly equal to that of raising it by bullocks with the leathern bag. There is nothing like leather, and until a small machine can be invented suitable for irrigating about one acre per day, and for lifts of various heights up to 60 feet, the *mote* will continue to be the popular method of raising water. The pious Virgil probably had in mind the fact that agricultural machines to be popular must be cheap and suitable to small holdings, when he wrote, "*Possit ipse colendi Haud fastidium esse viam voluit.*"

There is nothing like open competition to arrive at the best method of accomplishing anything, which by individual

effort has so far proved a failure; and this has been recognised even in the case of the utilization of the urine of house-fed animals as a liquid manure, for we learn that the Directors of the Highland and Agricultural Society, having had their attention drawn to the subject of the utilisation of the urine of house-fed animals, found that on many farms, especially in dairy-farming districts, this substance is allowed to go to waste, as its use is said to be unprofitable owing to the heavy cost of handling it in its natural state. They have therefore resolved to offer a prize of £400 to any one who shall discover a practicable method by which the valuable constituents of urine may be most profitably utilised. Their offer is subject to the following conditions:—

1. The method must be capable of being adopted by farmers on their own farms.
2. It must be sufficiently moderate in cost to bring it within the reach of tenants of small holdings.
3. It must be sufficiently simple to be understood and carried out by farm labourers of the ordinary class.
4. It should be applicable to all classes of farms, including dairy farms where no litter is used.
5. The expense of the process must be so small as to leave a nett profit of at least one-third of the total value of the urine operated upon.
6. The success of the method must be proved to the satisfaction of the directors, who shall have the sole power of judging or appointing judges, by means of such practical tests as they may deem necessary.
7. In the event of a method being discovered which the directors consider to be feasible, they are willing to contribute liberally towards defraying the expense involved in putting it to a satisfactory test.
8. The communications of all candidates for this prize shall be considered strictly private, but the successful candidate shall be required to relinquish all personal or patent right to his method, which shall become public property on his receiving the prize.
9. Full particulars regarding the methods of competitors must be lodged with the Secretary of the Society on or before 1st January 1887.

Should no method be discovered which has all the qualifications requisite for attaining the prize, the Directors may still award a prize of less value to anyone whose method has the merit of fulfilling some of the conditions, if they consider that it marks a distinct advance and improvement for the good of agriculture.

It is curious that out here no such inducements are held out for any special purposes, except in very exceptional cases, and the reward offered is anything but liberal. Take, for example, the case of the fibre-cleaning machine. The reward was Rs. 2,000 (£200). The efforts of the Bombay Government in the direction of improving the methods of raising water for irrigation purposes, have ended in smoke, and the matter stands just where it was before. By the offer of a reward for a machine, with the necessary conditions, some satisfactory results might have been obtained. This is a suggestion which we commend to the consideration of the Bombay Government.

THE AGRI-HORTICULTURAL SOCIETY, PUNJAB.

The *Englishman*, in its issue of the 11th instant, has reviewed the work of the Punjab Agri-Horticultural Society during the year 1884. This is what he says:—

"The public gardens of Lahore are among the finest in India, and the Agri-Horticultural Committee are to be congratulated on the improvement which they have been able to effect in the general appearance of 'Dustypore' of late years. The income of the gardens last year was Rs. 13,763, and of this sum the sales of garden produce represented Rs. 7,649: subscriptions, Rs. 4,184; and the Municipal grant, Rs. 1,512. Judging from the difficulty experienced in getting the last named sum granted this year, it would seem that local self-government does not regard with a kindly eye the improvement and adornment of the town." So far we entirely agree with our contemporary: but the following is such a characteristic effusion, that we quote it *in extenso*:—

"On the other hand, there is a decided advance in the sale of garden produce, which is not, perhaps, a matter for such un-

mixed congratulation as the Committee seem to imagine. Apart from the oddity of the Government associating itself with a thriving business in seeds and plants, there arises the question of private enterprise. It is all very well for the Committee to pride themselves on having reduced the price of fruit trees 11 per cent and of roses 11 per cent. But what about the private dealers in fruit trees and roses? There can be no doubt that the committee mean business. "The nurseries have been cleared of overgrown plants, land has been levelled and cleared, and the operations have resulted in a great improvement in the appearance of the gardens, and in the acquisition of more space for the propagation of fruit trees and for agricultural improvements. This is news which will hardly raise the spirits of 'the trade,' although it may please the people of Lahore. It cannot be denied that there is something at once unfair and undignified in the connexion of Government with a gardening concern—even if it can be described in the language of advertisement as "a good going concern." A State-aided Sutton's establishment would doubtless be hotly resented by those immediately concerned, and would be justly and generally condemned by the public. And yet the Punjab Government directly countenances a powerful rival of the various seed firms which are making an active effort to extend their business in India. The fact is that the policy which the Government is never tired of preaching is only intended in a Pickwickian sense. The Government reserves to itself the right of violating its own rules at every turn, and the private interest is sadly to be pitied that comes into collision with Government rivalry."

We fail to see how the Government can be said to be associated in this "Gardening concern." True, the Municipality makes a small grant towards the funds of the society, but that is only in the interests of the people who reside within Municipal limits, and who enjoy the pleasure of using the Society's gardens, and make a convenience of the place. The Society is supported entirely by private enterprise, and we cannot understand how the existence of these gardens comes into conflict with private enterprise in the sale of seeds and plants. A Municipal fund is not an Imperial one, but a local cess-fund, collected from the people of any town, and utilized for the benefit of the rate-payers. And if the tax-payers do not object to the application of a portion of their money for the purposes of a garden, nobody else has a right to object. The Agri-Horticultural Garden at Lahore is not a Government institution, nor is it Government aided. The Society is a private one, and the several Societies scattered about India have done an incalculable amount of good in the distribution of plants and seeds—in many cases gratuitously—and in providing fruits and vegetables of a superior kind to the people generally. This is not all; they have encouraged and spread a desire for high class horticulture and agriculture, and improved the quality of cultivation generally in India by example. They have been the pioneers of Agri-Horticulture in India, and as such, deserve all the praise and encouragement they have received. There is a genuine Government garden at Lahore (and in many other stations for that matter) known as the "Anarkallee" garden, where, we believe, no plants and seeds are sold. But even supposing for a moment that a charge was made for plants and seeds in this garden, it is not to be expected that any one would think of getting them *free of charge*! An establishment has to be maintained and paid for, and if the garden earns a small income by such sales, it does not go to show that the institution is opposed to private enterprise. Its real and only object is to provide a place of pleasant recreation for the people.

There is something ludicrous in the analogy drawn between the horticultural gardens at Lahore and "a State-aided Sutton's establishment." We do not think our contemporary knew very well what he was writing about. The Society are to be congratulated upon the reduction they have been able to effect in the prices of plants; and have set an example in this direction to the other Societies in India. We hope ere long to hear that they have also reduced their rates of subscription for members. In this connection we direct attention to our observations elsewhere. The remark that "the Punjab Government directly countenances a powerful rival of the various seed firms which are making an active effort to extend their business in India," would never have been written had our contemporary been sufficiently

informed upon the subject which he attempts to deal with so summarily. It may be news to him to learn that the several Agri-Horticultural Societies in India are the *largest customers* the "various seed firms" have in India. A reference to any of the Societies (or to the seedsmen themselves) will convince him of the accuracy of this statement. As a matter of fact, the several Societies import large quantities of seeds from Europe and America for distribution to the hundreds of members who annually subscribe a certain fixed sum to the Societies. We are not concerned in defending the policy of the Government in the matter of its opposition to private enterprise, which our contemporary characterises as "Pickwickian," but we draw the line at Agri-Horticultural Societies, which we cannot regard as State-aided institutions in the strict sense of the term. They simply receive small sums from local funds, and nothing more, for which they render very often valuable aid to Government in its efforts to extend Agri-cultural knowledge among the people of India.

MINING INDUSTRIES IN BURMAH.

THE Administration Report for 1883-84 shows that of late years much attention has been paid to the development of the mineral resources of the Province. The various mining operations undertaken in different parts of British Burmah include coal working near Okpo in the Henzada District, and coal explorations near Thayetmayo; earth oil works in the Kyatpu district; lead mining in Tenasserim; and tin mining in the Mergui districts. In regard to coal, the experimental mining commenced by Government with convict labour in the Okpo township near Kywesin village on the Aracan Yoma, proved a failure, the works having to be abandoned in consequence of the unhealthiness of the locality. It is feared that, for many years to come, it will not be possible to bring this coal to market at a remunerative cost. This means that until the country shall have been opened out, and further facilities for carriage provided, there is no prospect of the coal in Henzada being profitably worked. This is much to be regretted in the interests of a Province, where railways are making rapid progress, and river steam navigation is a well established fact. In addition to the requirements of numerous rice, saw, and other mills in the country, mineral fuel is needed for a commercial marine steam tonnage aggregating 335,379 tons per annum. The prospect of better results in regard to indigenous coal at Thayetmayo is therefore hailed with satisfaction by the Provincial authorities, who have granted a concession to private enterprise in this district, where there is reasonable prospect of success. The preliminary operations show that the quality of the out-turn is good, and encourage a hope of the quantity being commensurate with payable results. Earth-oil is, in reality, the only well-developed mineral industry in the country, but we regret to find its progress not all that could be desired, the works being carried on with indifferent success. Notwithstanding the fact that there are three European Companies, besides natives, at present engaged in extracting oil in the Kyaukpypu district, up to the present time no large yield of oil has been obtained. The total out-put of the whole field was 400,325 gallons. So far nothing has been discovered in the Kyaukpypu field that can approach oil-bearing strata of the type of the good American or Caspian field. Hence the business of oil-mining on a large scale in British Burmah has not been a success. The Arakanese (native) workers, who put down their wells and manage their proceedings more economically than the English firms, can alone be said to work the oil profitably. We are not surprised at this result, for mining generally in the East, when conducted by expensive agency, and where indigenous resources are neglected or not known, has as a general rule come to grief. The descriptive account of the chief oil source of Upper Burmah, given by the Government Chemical Examiner, contains nothing new or different from what may be obtained from Dr. Balfour's *Cyclopsæa*. In treading stale ground Dr. Romanis follows old paths in a known domain. Mr. Law's lead-mining enterprise in the Salween is not as yet an assured success. The presence of galena in this part of the province, though for a long time known, did not

attract attention for the purpose of working till lately, when the lease of a large tract of hill country at Titawle in the Kadingti circle was granted by Government under favorable auspices, but owing to drawbacks from want of labour and carriage, the result has not been all that could be desired. Galena, containing a high percentage of silver ore, is likewise found in the Karen Hills sub-division of the Toungoo district, whence the annual out-turn is about 50 tons. Lead is also found in the island of Maingay; and both lead and antimony are found in the Anaherst district. All these localities are in the Tenasserim division. With great capabilities, the tin industry is languishing in Mergui in sad contrast with the prosperity of the Malayan and other fields further south. This ought not to be; and it is satisfactory to find that it is proposed to make a thorough inquiry into the subject of placing tin working in Mergui on a better and more reliable footing. Iron is found in Shwegyin, but not worked. Gold is obtained in the same district from placer washings, the "pay-dirt" being obtained from the bed of the Thayetpiindae, a stream which flows into the Shwegyin river.

From these brief notices, it will be apparent that the mining industries in Burmah are capable of great development, and we have endeavoured here to direct attention to a subject of much commercial importance. It is for the trade and the Government to take up the matter, and we hope to hear soon that advantage has been taken of the large mineral resources of Burmah.

CHINSURAH AGRICULTURAL EXHIBITION, 1886.

WE have received the following particulars of an influential public meeting of the chief residents of the Houghly district, which was held at Chinsurah, on the 10th instant, at 6 P.M., to consider the advisability of holding an Exhibition of agricultural produce, and implements, next cold weather, at the place:—Among those present were Baboo Doorga Churn Law, C.I.E., in the chair, Mr. B. Dey, C.S., Prince Amiruddin Ahmed, Moulvi Ashrafuddin Ahmed, and others interested in the subject. Before the proceedings commenced, Mr. Dey read some letters from gentlemen of the district, who were unavoidably absent from the meeting, but who expressed their entire sympathy with the proposed exhibition, and offered their hearty co-operation in the furtherance of the scheme. The chairman, while asking Baboo Onooroop Chunder Mukerjee to move the first resolution, dwelt on the necessity of having an Agricultural Exhibition, on the ground of its conferring manifold advantages on the ryots of the district. Baboo Onooroop Chunder Mukerjee then moved, "That it is desirable that an Exhibition of cattle, agricultural implements, and products—fruits, flowers, and vegetables, and articles of manufacture, should be held at Chinsurah in the ensuing cold weather." He delivered a speech, in which he dwelt on the benefits which are expected to result from an agricultural exhibition, and said, that although some of the principal zemindars of the place had been unable to attend the meeting, owing to inclement weather, and other causes, still, he was in a position to say, that the proposal had their fullest approval, and that they would try, by every means in their power, to further its cause. This was seconded and supported, and Baboo Eshan Chunder Mitter, Government Pleader, then delivered an address. The resolution was then moved by Baboo Joy Govind Law, "That an Executive Committee, consisting of some of the leading residents present, be appointed, with power to add to their number to carry out the necessary arrangements, and collect funds." This resolution was supported by Baboo Khoro Nath Dey, who said that exhibitions of this kind were not quite unknown to the country. While he was a school-boy, he remembered that exhibitions used to be held every year in Houghly under the patronage of Mr. Russell, the then judge of the station. He also said that an exhibition of agricultural products and implements was held at Alipore in 1863, during the Lieutenant-Governorship of Sir Cecil Beadon, and the Government had then passed a resolution, authorising the expenditure of Rs. 30,000 annually on exhibitions, and that in furtherance of this resolution, exhibitions

were held in Burdwan, and elsewhere. It was resolved to send circulars to all the leading zemindars and other residents of the district, requesting their help and co-operation.

A VALUABLE ONION.

DR. E. BONAVIA, who is a prolific writer on Agri-Horticultural subjects, has contributed the following letter to the *Pioneer* in which he brings to notice the existence of a valuable and prolific onion. We reproduce the letter *in extenso* for the benefit of our readers:—"I write these few lines with the hope that you may be good enough to allow them a little space in your columns, as the best means of making this vegetable widely known. Many years ago, one Fakhri Hussein, a Vakeel of Lucknow, obtain some seed of this onion from Rahimabad. He gave it to Judge Fraser, and through the latter it came into my hands. I sowed it in the Lucknow Horticultural Garden, and found that it was capable of great progress. For many years afterwards, I selected the best for seed and reproduced it. When I left Lucknow, Mr. Ridley continued this good work. After coming to Etawah, I obtained some seed of this remarkable onion from Lucknow, and sowed it in the jail garden. By this time, this white onion had gone through more than 15 years of acclimatization and selection in the Lucknow gardens. The result of the sowing in Etawah showed that its pedigree was as good as ever, and that it probably was one of the finest strains of this vegetable yet raised in India. I again selected the best and finest bulbs for seed, and this year I have a fine lot of seed. A seer of seed produced 58 maunds of onions for use, besides 2 or 3 maunds kept for seed for next year. The soil was not very well prepared. This onion is sweet, mild, and very nutritious. As it is ripe at the commencement of the hot weather, when every other vegetable excepting watery pumpkins has disappeared, it is very useful for general use, but especially for soldiers, prisoners and others, for whom vegetables are most important as preventives of sickness. I remember reading in some ancient history that the Pyramids of Egypt are supposed to have been built by people who during their hard task got little else to eat but onions. It is well known that onions, even now, are one of the great vegetable products of the Nile delta. I think there can be little doubt that if the Egyptians in those days had such a fine vegetable as the present white onion of Lucknow, many more Pyramids would have probably been left for posterity to admire. This onion is very different from the bazaar onion. When boiled or otherwise cooked, it has not the rank flavour of the native onion, and is delicious in whatever way it may be dressed. A word about its cultivation. This useful bulb, by training, can be either an annual or a biennial. The former germinates from seed, grows, flowers, and seeds—all in one season. But in seeding the bulb is used up—and nothing is left; all that remains is the seed. So that, as an annual, the onion can only be used from the time of germination to the time of showing flower. On the contrary, as a biennial, it germinates, grows, and forms a fine bulb the first year. So that it can be used both in its green state and in its dry state. The next season then the largest and finest single bulbs are selected about October and replanted in rich soil for seed. The golden rule is—for seed, always keep the strongest and finest and best shaped bulbs, and always plant in rich soil, and let water never be wanted. For, from this seed the next generation is to come. Also, for seed, keep the best and strongest heads of flower. By seeding, the onion, as I said, is used up. It will thus be seen that the biennial variety is far the more useful. I am not prepared to say whether the onion—a close relative of the lily—was, in a state of nature, annual or biennial. I am inclined to think that it was an annual, and that by cultivation a biennial variety turned up and being more useful was selected and fixed. In a field of first-year onions a small number will be observed throwing up flower stems. These should be scrupulously eradicated and sent to the kitchen. If left to seed, the crop will be leavened by the annual variety, and rendered comparatively worthless. The object of the cultivator should be to keep the onion strictly a biennial. To keep the bulbs from spoiling, they

should, in the first instance, be well dried in a current of air, and then kept in a cool place either on shelves or on sand, one close to the other, without touching, and away from the inroads of white-ants, rats, and other enemies. The cultivation of the onion is very simple. Sow in October in beds of prepared soil with some wood or charcoal ash. This selected seed is so good that it all germinates at once. Water regularly. Should the young plants at any time look unhealthy and yellowish from poverty of soil, give them a sprinkling of ashes, and then a watering. In a few days, as if by magic, the plants will become as green as grass. Let me mention that there are few things more delicious than very young onions, eaten with bread and butter. As soon as the plants are large enough to handle—say of the thickness of a pencil—they should be pricked out 6 or 8 inches apart, in good soil, and watered. The better the soil and the more regular the water, the better the onions and the larger will be the produce. In April the green leaves will wither, and the bulbs will be ripe to lift and store. I repeat that any which attempt to flower the first year about March or so, should be uprooted and utilized. It is a mistake to fancy that the green leaves of the onion are of no use. They are simply the choicest and most delicately flavoured part of the onion plant. For flavouring dishes, soups, gravies, salads, &c., cut up small, they are fine. But as a vegetable, of course, the bulbs are the most useful part."

Miscellaneous Items.

A RUSH of water came down all the local rivers in Purneah during the past week, but as yet the damage done has been inconsiderable.

We are informed that at the water-works scheme meeting in Moufferspore, it was decided that the Municipality should draw out an estimate for the scheme, the money to be raised on debentures, interest being met from taxation. Patna may very well take a leaf out of the book of the sister city.

THE general market at Bangalore is well supplied now with both vegetables and fruit. Of the latter, apples, figs, pomegranates, strawberries, and guavas are all in season, and sell at reasonable prices. The mutton stalls are tolerably well supplied, but as to the beef—why, it is a scandal to the station. The horticultural show at the Lal Bag ought to be a success.

THE great heat and scorching land-winds which made Pondicherry very uncomfortable about a fortnight ago have nearly left the station, and now there is a good share of sea breeze during the greater part of the day, and frequent showers of rain. The ryots are hurrying, though very late, their sowing of the commoner kinds of edible grains, the prices of which have been rising for the last few weeks. The indications of more rain are favorable.

THE Straits Settlement would appear to be no great place for growing potatoes in, for we find that local traders are despatching large quantities of the tubers for shipment to Penang. Very recently about six thousand pounds were despatched by rail. At this rate potatoes will rise in price here, and it is to be hoped the Eurasian and Anglo-Indian Colonists will cast such exceptional industries as ostrich-farming and mushroom cultivation to the winds, and take to the growing of potatoes which, we can assure them, will give them a better return than the two first mentioned.

THE report of the Upper Sind Horse Show, just to hand, shows the total number of animals exhibited to be 815, consisting of 411 mares, 91 fillies, 44 yearlings, 114 horses, 43 colts, 22 geldings, 12 donkeys, 20 mules, 6 cows, 11 bullocks, and 31 camels. The show, though called a horse show, was more of a show of live stock on a small scale. The increased popularity of such shows was evinced by the increased number of animals in this case. The entries in the classes of mares and fillies showed them to be in good condition and of good quality; but the horses are alleged to be a poor lot. Owing to the momentary expectation of rain, the usual system of judging by marks was dispensed with. The number of geldings entered in all classes was only 19. Hockey stallions are reported to be doing well. But of ordinary donkeys, riding camels and horned cattle, there is not such a favourable report as to quality.

The Indian wheat trade has shown signs of improvement this year so far as the quantity exported goes. During the first quarter of the current year, nearly 201 lakhs worth of wheat was exported, against less than 157½ lakhs during the same months of 1885. The exports to the United Kingdom show an increase of over 56 lakhs. The exports to France and Egypt fell off; but there was a large increase in exports to Belgium, Holland and Italy. The exports of Indian tea show a considerable increase. Over 30 lakhs worth of tea was exported, during the quarter, to the United Kingdom; against less than 16 lakhs worth in the same quarter of last year.

The deaths in Bombay from cholera during the past week had decreased to eight. The summary of the season reports states that there has been slight rain in most districts; but more is wanted in parts of Sholapore, Admednugger, Poona, Bijapore, Nasik, Khandesh and Dharwar. Young crops are withering in parts of Sholapore, Khandesh, Bijapore, and Thana, and are injured by insects in parts of Hyderabad, Upper Sind Frontier, and Bijapore. Fodder is scarce in parts of Khandesh, Sholapore, Nasik, Ahmednugger Poona, Bijapore, and Belgaum. Cholera prevails in parts of eighteen, fever and cattle-disease in parts of nine, and small-pox in parts of four districts.

Two telegrams have recently been forwarded to the Chief Engineer, Bengal, P. W. D., Irrigation Branch, by Baboo Makhundo Lal Chowdhry, Zamindar, Bahabpore, and president, Agricultural Association, that, owing to the closing of the irrigation sluices, agricultural operations, which depended upon the supply of water by the Eden Canal, have been completely stopped. The prospects, it is said are very gloomy; and if the canal is not re-opened, eighty thousand cultivators will suffer by it. Distress is already existing, and scarcity staring them in the face. The applicants are even willing to pay a proportionate cost of silt-clearing charges. The paddy plants, which have been transplanted, are withering, and the time for the operation will be closing immediately.

"C." writes to us:—"As I find from your paper that the Madras Government has ordered the stoppage of further work in connection with the Artesian well at the People's Park, upon a report from Dr. King of the uselessness of boring through the sheet of rock which has been struck, I would like to know on what grounds Dr. King assumes it impossible to strike water below or within the rock. I believe that rock and stiff clay are the most likely strata in which springs of water exist, caused by percolation through them from higher lying strata, and it seems to me a mistake to stop short when the most likely soil in which springs abound is reached. Dr. King is a clever geologist, and stands well with the Government, but after all he may possibly err. I would recommend the boring to be continued to a further depth of 50 feet or more, before abandoning what has been begun at so great a cost."

Selections.

SILOS IN BURMA.

The following papers are published for the information of people proposing to make silos in Burmah. For transport cattle and other Government animals at places like Rangoon or Thayetmyo, economically managed, silos may be useful. But all the sanctioned experiments with silos in the districts have now been completed, and no more such experiments will be undertaken at the public expense for the present.

J. E. BRIDGES,
Offg. Secretary.

Memorandum by F. W. CAMANISS, Esq., Assistant Director of Agriculture, British Burmah, on Silo-pits at the Kyauktan Farm,—dated the 10th July 1885.

On the 10th July 1884, two silo-pits had been dug and were ready to be filled. The first pit was circular, five feet in diameter, and 15 feet deep. The second pit was also circular, slightly larger at the top than at the bottom, seven feet deep, and on an average of five feet in diameter.

2. Nine men started on the 10th July to cut grass near the pit, to fill it, and by the evening of the 12th the pit had been filled and the weights put on. This was pit No. 1. By the 15th July the weights had settled six feet; six feet more of earth was

therefore, placed on the top of the pit. By the 30th July it had settled 18 inches more, and earth was again piled on. After this, the weight ceased to settle. On the 9th July 1885, this pit was opened, and the contents found in perfect condition.

3. On the 21st July 1884, pit No. 2 was filled by nine men in one day, and the weights placed on it. Five days afterwards it had settled four feet, earth was piled on it, and it ceased to settle any more. On the 18th May 1885, this pit was opened, and its contents were found in good condition, with the exception of about two inches on the top and one inch around the sides, which had moulded and was black. When this silo was opened, the farm buffaloes ate the ensilage, but at the time silo No. 1 was opened, they would not touch the ensilage, from either pit, as plenty of fresh grass could be had of the same kind, of which the ensilage one year previously had been made. Horses would not eat it at any time.

4. The cost of silo No. 1 amounted to—

	Rs.	A.	P.
Cost of digging	10	0	0
Cost of filling, &c.	13	8	0
Total	23	8	0

This silo-pit contains food for four buffaloes for one month. The cost of employing a man to graze 12 buffaloes is Rs. 24 for one month. This shows that in this section of Burmah it will cost three times as much to keep buffaloes by feeding them from the silo as by grazing them.

5. In making the above statement, I have taken the district rates for labour, namely, for a pit five feet in diameter, Rs. 1 per cubit depth; cutting grass, or a day's labour per man, eight annas per day; grazing one buffalo, Rs. 2 per month. The silo in this section of Burmah is, therefore, at present useless. This, however, may be changed in the course of time if labour becomes cheaper, and if there are less facilities for grazing cattle.

6. My experiences with silos are that they are principally useful, namely,—

- (i) when it is necessary to preserve cattle-food rapidly;
- (ii) when it is wished to preserve green food for a time when the soil does not produce it;
- (iii) when it is cheaper to take a large quantity of cattle-food from a small area of land.

7. Thus we have in Thibet (the place where, I believe, ensilage first originated) a small area of cultivable land for a short time of the year only, so that the requirement is to save the food rapidly so as to get a second crop from the land, if possible, and also to preserve green food for a time when the soil does not produce it.

8. In America we have a large quantity of green food for cattle available in summer and none available in winter. The facilities for saving the ensilage by machinery also add to its advantages in America.

9. In India the rains might be compared to the summer of America, as it is the time of plenty, and the dry season to the winter, as it is the time of scarcity of cattle-food.

10. Cheapness of labour in India compared to relative value of land in India also takes the place of advantages of machinery in America.

11. In England and France land is valuable compared to labour, and this favours ensilage; while here, in Burmah, it is just the reverse, labour being expensive and land (for grazing) free.

12. The silos were not opened earlier because the farm cattle, as well as the cattle in the neighbourhood, were not at the farm, but away grazing during the hot months of the year. Ensilage is not valuable at any time in the Kyauktan sub-division, where the farm is situated.

13. Under the above circumstances I, therefore, recommend that no more money be expended by the Agricultural Department in experiments with silos in this section of British Burmah.

From Colonel W. C. PLANT, Commissioner of the Tenasserim Division, to the Secretary to the Chief Commissioner, British Burma, Land Revenue and Agricultural Department,—No. 1415-117, dated the 22nd June 1885.

With reference to your letter No. 1412-70, dated the 23rd June 1884, I have the honour to submit, for the information of the Chief Commissioner, copy of letter from the Deputy Commissioner, Toungee, with enclosure, reporting on the experiments in silos in his district.

Silos, to be of any advantage, should be packed in time to be fit for opening when the hot weather has set in, and fodder and straw difficult to get, say, packed in July and opened in February.

From Lieutenant-Colonel W. O. HUGHES, Deputy Commissioner, Toungoo, to the Commissioner of the Tenasserim Division,—No. 4-249 (Agri-Horticultural), dated the 11th June 1885.

IN continuation of my letter No. 5-423, dated the 31st July 1884, I have the honour to report that two silos—one at Yedashe, and the other at Oktwin—were constructed and stored with grass in December last. The silos were opened last month, and the results of the experiments, as reported by the Myooks, appear to be unsatisfactory. Copies of the reports are enclosed, as also a memorandum by the Myook of Zeyawadi in reply to a letter from this office, asking him to report how far such a system is called for in his township and appreciated by the people. In a district such as Toungoo, where there is abundance of pasture, except for two or three months in the hot weather, when straw is supplied as fodder, I am inclined to agree with the Myook that the prosecution of the experiments is unnecessary.

From MAUNG KHIN, Myook of Zeyawadi, to the Deputy Commissioner, Toungoo,—No. A, dated the 20th May 1885.

WITH reference to your memorandum No. 51202, dated the 24th March 1885, I beg to report on ensilage as follows:—

2. I dug in my Court compound a pit 10 feet long and 5 feet deep, sloping from 5 feet broad on the top to 4 feet broad at the bottom.

3. I got four cartloads of grass,—two of which were "doob" grass, and the other two long grass from the paddy-fields. The grass was put into the pit in December 1884. It was trodden down by men as it was put in. I closed up the pit by covering it with two mats, and placed the excavated earth over the mats.

4. I opened the silo yesterday in the presence of Burmese gentlemen, Maung Tu and Maung Gyi, (members of the Rural Board). I herewith beg to send you in 5 baskets samples of the two sorts of grass that were ensilaged.

5. The top and bottom of the ensilaged was slightly decayed, but the middle portion of the same was good and sweet. I have given a good portion of this grass to the bullocks, and they have eaten it. The cost of the silo was Rs. 16-4-0, and I think the experiment has been successful.

From MAUNG PAN BYN, Myook of Thagaya, to the Deputy Commissioner, Toungoo,—No. 44, dated the 1st June 1885.

THE Thagaya Myook, Maung Pan Byn, begs to report on ensilage as directed in letter No. 8-177,—dated the 27th May 1885.

(a) The grass was put into the silo on the 9th December 1884.

(b) The silo was opened on the 9th May 1885. Some of the ensilage was like straw, some was of a green, and some of a dark colour. Cows and ponies only ate it when they had been deprived of other fodder, and even then only in small quantities.

(c) There is no use for ensilage in my township: straw is plentiful and better.

From MAUNG KHIN, Myook of Zeyawadi, to the Deputy Commissioner, Toungoo,—No. 6, dated the 7th June 1885.

IN reply to your memorandum No. 5-221 R.D., on the subject of ensilage, I beg to report that I have consulted the cultivators about the ensilage. They tell me that it would be only entailing extra work on themselves if they made ensilaged grass, as they have sufficient grass for their cattle throughout the whole year, and they do not appreciate the same for their cattle, fearing the cattle will grow thin. I, therefore, do not think it desirable to continue the experiment.

From the Officiating Secretary to the Chief Commissioner, British Burmah, Land Revenue and Agricultural Department, to the Commissioner of the Tenasserim Division,—No. 1290 2C., dated the 26th July 1885.

I AM directed to acknowledge the receipt of your letter No. 1415-117, dated the 22nd ultimo, submitting reports on the experiment made in silos in the Toungoo district.

2. Two experiments were made by the Myooks of Zeyawadi and Thagaya townships respectively, and both appear to have been

fairly successful in so far that the ensilage was found after five months' keeping to be palatable food for cattle. The cost of the Zeyawadi experiment is given at Rs. 16-4-0, and this appears somewhat high when compared with the amount of grass obtained. In Toungoo, and in nearly every district in Burmah, there is sufficient grass for the cattle, even during the hot months of the year; cultivators will not, therefore, go to the expense and trouble of keeping grass by artificial means whilst their cattle can find fresh grass throughout the year. It appears, moreover, that the cultivators show the usual suspicion of any novelty, being afraid that ensilaged grass would not fatten their cattle. Under these circumstances, I am to say that ensilage experiments need not be continued in the Toungoo district.

STRAWBERRIES BY THE TON.

BY ONE WHO LIKES THEM.

It may have been an exaggerated estimate of the value of his time for the guard in "Alice's Adventures" to declare it was worth a thousand pounds a minute, but it would be quite within the mark to say that in the fruit-growing districts just now a good shower of rain might be valued at that rate. Seldom has there been such a crop, in the southern countries at all events, of fruit of all kinds, which need but frequent showers of rain to make this one of the most prolific of seasons. Without the much needed rain, however, there will be no dearth of fruit, as the appearance of our shops and the hawkers' barrows testify. Within the last few days strawberries of good sorts and of large size have been retailed at four pence a pound, and even at this rate there has been a large profit to the producer. Few Londoners have any idea of the extent to which this fruit is cultivated in the neighbourhood of the Metropolis. A day or two since we were in a field at Baxley, from which on the morning of our visit there, had been picked and sent off before eleven o'clock two tons of strawberries. We had heard of the fruit being picked and sold by the ton, and we determined to learn more of the culture of this delicious fruit, which was produced in such quantities so near London. Having appointment with the worthy farmer we had no difficulty in finding him, for rows of pickers indicate where the fruit is being gathered. The air is redolent of strawberries, not faint, as when they are kept in a room, but fresh and luscious. Here is a field of sixteen acres, with fruit in various stages. The part of it where the pickers now are has been gone over four or five times, and still yields abundance. There are some two hundred women and children and a few men, most of them resident in the neighbourhood, but there are a few from London. At Sidcup we saw an encampment of gipsies, about a hundred, come to take part for the first time, we believe, in fruit-picking. The pickers are supplied with wicker baskets, holding 5 lb., which are taken, when full, to the man who weighs them for market, and as each basket is brought in the picker gets a ticket, which represents a money value according to the crop. To-day the fruit is not large, and is being picked for jam; the strawberries are, therefore, "strigged," or picked without the stalks; when gathered for table they are "plummed." Fruit is worth now three-halfpence a basket for packing; by-and-by, in the afternoon when the picking begins for the table fruit, so that it may be sent off at once to arrive fresh for the morning's market, the rate may be reduced to a penny. The pickers have been at work since six, and as has been said have gathered over two tons. As in other callings, it is the quick-fingered who excel. Very dextrously some of the pickers lift up a plant and remove the ripe fruit; some of the girls seem as quick as any. The pickers can earn from five to three shillings a day, according to their dexterity and the fulness of the crop. Here is a boy who can earn four shillings a day and no wonder that schoolmasters and mistresses complain of vacant places during fruit season. At first thought one might suppose that the employment of boys and girls to pick strawberries was of doubtful expediency; and so it might be if fresh hands were employed daily, but they soon have it enough, in most cases too much, and after the first day very few strawberries find their way to the mouth. Indeed, so confident are the growers that things will right themselves that not even a prohibition as to eating is given to the pickers when they are engaged. As a matter of fact, we observed the pickers at work, and only saw one strawberry eaten while we were in the field. The old man engaged in receiving the fruit and weighing it—a stolid old fellow who had been at this work for many years—did communicate this much, that he had not tasted one all the

season. Fortunately for consumers, the cultivation of the straw-berry is a profitable occupation, in spite of the shortness of the season and the exigencies of weather. This year, in this part, picking began on or about the 24th of June, and will last till the middle of July. During the season the plants to come to perfection require many hours' rain daily, with hot sunshine between. This year, in the absence of the much needed rain, many tons of unripe fruit will not ripen at all. In the spring, the large jam-makers contract to take the fruit at so much a ton. When it is likely to be scarce it may fetch £50 a ton, if the crops promise well it may be sold for £25. But even at the latter rate the industry must be a profitable one. Fresh plants are sown in November, but are not allowed to fruit until the second year; they arrive to perfection in three years, and will continue to bear well for six years. They are hardy plants, and do not require much cultivation. The ground is dug up or ploughed in the winter, and afterwards manured. In the spring straw is put underneath the plants to keep the fruit from being beaten into the earth by the rain. Few crops, we should imagine, of so prolific a character cost so little for labour to cultivate, and when the cost of picking is added there must be a handsome margin for the grower, even in an average season. Take this year, though doubtless it is more than an average one: some land will yield perhaps from two to three tons an acre; taking the fruit at so low a price as £20 a ton, and the cost of picking at three-halfpence for five pounds, which comes to £2 16s. an acre, there must be left a very large margin for rent, cultivation, and exigencies, and glad are we it is so, not only because the delicious fruit is so popular, but also because it affords another proof that fruit growing, to which the attention of British farmers is so constantly urged, may be made highly remunerative.—B. C.—*Pall Mall Budget*.

THE WOBURN EXPERIMENTS.

In a lecture on 'The Practical Uses of Field Experiments,' delivered at Brighton during the late show, Dr. John Voelcker, the new consulting chemist of the Royal Agricultural Society, threw some light on the problem presented by the singular results of the Woburn trial of highly nitrogenous against poorly nitrogenous manure in a rotation of crops. Instead of appealing to some extraordinary richness of the light soil in nitrogen to account for maize meal giving as great a produce as cotton cake, Dr. Voelcker said:—'Where clover is grown after a cereal, a quantity of nitrogen is found accumulated in the surface, which becomes richer in nitrogen than it originally was. This is the crop residue. If after clover, a legume of different habit, and growing its supply of food from different sources and levels, be grown, no heavy crop can be got. More nitrogen is found to have accumulated in the soil, chiefly near the surface when the clover is seeded than when it is mown, accounting for the experience of the farmer that the wheat crop is better after seeded clover than after mown.' Dr. Voelcker found 'in 6 inches depth of soil after a crop of clover as much nitrogen as is equivalent to 8 cwt. per acre of Peruvian guano. It would appear, then, that after the good clover at Woburn the soil receives such an accumulation of nitrogen, that it is able to produce a maximum crop of wheat with help of the low nitrogenous food maize meal, and that the extra nitrogen of cotton cake is not required. The wheat at Woburn next year is to follow tares and peas instead of clover, to try how cotton cake and maize meal measure will act then. Still, it is not explained why one manure does not surpass the other for the roots and barley.

Mr J. B. Lawes, writing on these experiments, says:—'In 1883 two of the plots of permanent barley, which had been manured with minerals and salts of ammonia, or nitrate, each yielded over 50 bushels per acre. The total produce on the two plots, straw and corn together, averaged 7,849 lbs. The plot manured with mineral alone gave a total produce of 3,422 lbs. lbs per acre, the deduction of which leaves 4,427 lbs. as due to the nitrogenous manures. The amount supplied was 400 lbs. of salts of ammonia and 550 lbs. of nitrate of soda, each calculated to contain about 36 lbs. of nitrogen. A barley crop, as carted from the field, would contain considerably less than 1 per cent of nitrogen, and I should estimate that the 4,427 lbs of crop contained between 40 lbs. and 45 lbs. of that substance, or about half the amount supplied in the manure. But we have to bring into our calculation the unexhausted residue recovered in barley grown in the succeeding years, which amounted on an average of three years to ten bushels per acre. The nitrogen con-

ed in these 10 bushels, including the straw, would amount to about 9 lbs., making a total of about 50 lbs. recovered out of 86 lbs. supplied. It should be stated, however, that in the corresponding wheat experiments there was little or no effect from the unexhausted residue of the manure in the first two years, but a considerable effect in the third year, after a dry winter, and doubtless little loss by drainage. If such is the case in a field under careful experiment, and where there were no weeds to rob the crop of a portion of its food, it is obvious that considerable loss must take place in the ordinary application of these manures; though it is true such heavy dressings are not employed in practical agriculture.—*North British Agriculturist*.

NARCISSUS FARMING IN THE SCILLY ISLES.

Few of the seafaring folk who pass and repass the Scilly Isles on their way out and home, have any idea that the much feared rocks and islands are the seat of a large and rapidly developing horticulture. There was a time when Scilly was a name familiar to the *habitués* of Lloyd's; now it is more often heard in Covent Garden. For among the low hills of St. Mary's and Treco, the narcissus, in all its forms and variants, blooms, and flourishes, and increases. Earlier in the salesman's hands than its Riviera rival, more pleasant in the purchaser's eyes to look upon than the Jersey lily, its progress as a flower favourite has been distinguished and triumphant. Among the farmers of the Cassesterides the narcissus has effected a social and financial transformation. Not so long ago, a man's consideration with his friends had, in some sort, a connection with the number of baskets of new potatoes he could, while spring was yet young, despatch to delight the plates of metropolitan gourmets. There still is poetry, for the island agriculturist, left in the potato, but the smile, born of hope and prospective profit, is reserved for the bulb of the narcissus. That bulb, too, is not, like the potato, massacred to make a meal for man; it is, after the flowers are sent, left in the soil to increase in productive capacity. Every bulb becomes at least two, sometimes three or four or five, in the course of the year. A little judicious replanting and separating are needed to achieve results in the way of fruitfulness and multiplication, which throw utterly into the shade the Egyptian performances of the children of Israel. Every steamer that left Scilly last spring for Penzance, in Cornwall, carried one of the fairest and most fragrant of flowers by the hundred thousand. It is sad to think that those very steamers have afterwards conveyed their myriads of mackerel—and at least for those subtly sensitive to sweet odours. Small farmers, who own from but twenty to forty acres, have suddenly found themselves *vis-à-vis* with a most promising prospect. Incomes have risen from a hundred to six hundred a year with an alarming rapidity. Alarming! nothing but yellow fever can be compared to it. In the West Indies they conceal the malady for fear of frightening the people away. In Scilly they hide the blessing for fear the foreigner may come in and appropriate some of the leaves and fishes. Self-interest is strong everywhere, but it should not hinder the world from learning something about a beautiful industry.

It is a moot point who introduced the narcissus and the lily into Scilly. Some say Mr. Augustus Smith, and some say the Monks; for the Priory at Treco from—we believe—the days of Athelstan to those of Henry VIII, was the abode of devout brothers of the Catholic faith. Mr. Augustus Smith was not a monk; but there are those who say that he at least recognised the peculiar susceptibility of the island soil to the blandishments of the narcissus. Perhaps, as the snake by a mysterious law of nature was banished from Ireland, the narcissus was fated to have its most fruitful and best loved home in the Cassesterides. However, the origin of the narcissus culture in the low-lying but beautiful little islands of the West may be accounted for; this fact is certain, that such varieties of the narcissus as *Democritus*, *Tolson d'or*, *Scilli d'or*, *Louis d'or*, *Gloriosa*, *Isabella*, *Baselman major*, *Baselman minor*, *Czar of Muscovy*, *Grand Monarque*, *Jaane Supreme*, and so on, flourish there and abound. The foam rising from the seacrests of the Atlantic as they beat themselves to a height of two or three hundred feet against Peninnis Head, against the Palpit

Rock, or against Giant's Castle, is blown here and there into every nook of the island valley. Yet the narcissus does not seem to mind. The south-westerns loom heavily in dark storm-clouds, and then burst in furious, gusty squalls, and the farmer goes forth to find his lily stalks a little bent perhaps, but for all that saved from all crucial harm amid the sheltering sheaves of the lily leaves. At Rocky Hill, and in some other parts of the islands, the force of the Atlantic gale is broken by the thick intersecting ridges of *macrantha*, which in themselves are one among the wonders and beauties of the Casalterides. The plucking of the narcissus is not unpleasant work. The stalk breaks with a crisp noise not at all disagreeable to the senses. As a matter of fact, although we have spoken lightly of the effect of the gales, the grower is apt, through anxiety to be over-careful. He cannot bear that the bright fresh flowers should be blown about by the storm, and so have their petals bruised and shattered. He cuts them while they are yet in bud, and before Eurus and Boreas can vauntingly display their baneful power. He places them in lukewarm water, over his kitchen oven, and then the narcissus opens itself in all its simple loveliness, untarnished by the hurricane, and fit for Covent Garden. It may be asked where Scilly gets all its narcissus bulbs or lily roots from. Well, from Holland. Holland is the ancestral home of the tulip, and equally profitable has it made the culture of the narcissus. It is running over with bulbs, and these it exports to the votaries of floriculture. The Scillonians have bought from the Dutchmen, and not content with buying, they purpose, on their own hook, setting up a bulb manufacture. They see that the gardeners of Holland make a great industry and large fortunes out of the export of roots, and they are conscious of no reason why they should not do the same. Although Scilly contains not so very many hundred acres of cultivable soil, the inhabitants hope to make the most of every yard which the Atlantic does not directly attack, and in so doing, read a lesson to other agriculturists.—*Pall Mall Gazette*.

NOTES ON TEA.

By Percy Spinkburne, late of Sylhet, Cachar, and Assam.

Cultivation.—The young plants should remain untended for a month after being transplanted to prevent any disturbance of their air roots, and to allow them to recover from the shock. The jungle between them has now grown such a length that if no further cultivation could be given, it would be necessary to clear it away with the *dhon*. Each man should not do less than 60 *mulla* of this work, unless from some misfortune the jungle has been allowed to grow for two or three months, when 30 *mulla* is enough. Any jungle which grows within a foot of the plant should be weeded, but if the jungle is allowed to grow too long, much damage is done to the young plant. First, the plant is weakened by closely shut in by jungle, and next when the jungle near it is pulled up by the roots, large balls of earth are removed with the jungle roots which have now taken firm hold of the ground, and the little seedling is shaken and its roots disturbed.

The best treatment is at the end of the month to hoe gently all round the young seedling, but great care must be taken. The hoe must not strike within six inches of the plant—that is, a circle of a foot in diameter must be left with the plant in the middle. The hoe stands close to the plant, and hoes over it, drawing the earth towards the plant; he then turns gradually round, repeating the operation until the circle is complete. Now he places his hoe on one side, and with his hands pulverizes the soil and draws it back from the collar of the plant. Each of the plants now stand in the centre of a hoed clean circular space of about 1½ to 2 feet diameter. The land remaining between these spaces need not be hoed until the end of the year, and the jungle on its being repeatedly chopped with the hoe gradually dies out. This work can be done for 1½ *kazree* for a piece of 16 bushes square, 4 by 4 feet planting, 256 bushes, 28 4/9 *mulla*; and afterwards as the work gets lighter, it can be reduced to 1½ and 1 *kazree*. It should, however, be borne in mind that this work is much heavier in close planting than in wide. There are 270 bushes in 30 *mulla* planted 4 by 4 feet square, and only

173 in the same space planted 5 by 5 feet square. This pulverizing should be repeated at least once in six weeks, and not oftener than once in three weeks. Bamboo stumps or other troublesome jungle which is hard to kill should be smothered with cut jungle and clods of earth. The heat generated by fermentation kills the young shoots effectually and the stumps die, and can be easily hoed away the next year, when it will have become rotten.

Roads.—The main section roads north and south and east and west are made first of all, and the section roads are made according to the nature of the land at the time of planting, but the cart roads on broken land require to be made with much judgment as they must run to every part of the garden, and all sudden ascent must be avoided. If they are made too early and before the lay of the garden has been carefully studied, it nearly always happens that they run in the wrong direction or a straight where they should wind, or *vice versa*. They should be not less than 12 feet wide, and it must not be forgotten that the chief object of a cart road is to enable the traffic on it to be conducted with the least possible expenditure of force. A road should therefore be taken a long distance in order to lessen a gradient. A gradient of about 1 in 20 is not too steep for a cart road. "Road tracers" should always be used when a road is either taken up or round a hill. They are very simple and easily worked. The plants which are lifted from the roads are used for filling up vacancies. The lines, if possible, should be near a navigable stream, and a cart road can be made to run from the ghat on the stream through the lines to the garden. Artificial manure can then be carted from a godown at the ghat to the garden paths round the edges of *teals*, and round the outer edge of the whole garden are very useful both for supervision, and to prevent the encroachment of the jungle and loss of bushes from jungle fires. A path round dark corners and inaccessible places, injures good work in those places even if the path is seldom used. Before leaving this subject, reference must be made to the numerous Government roads, the best of which have been made by planters. Only those who travel between the tea gardens and police stations in the rain, can form any idea of the disgraceful condition into which the roads are allowed to fall; and

although this in new districts and in good seasons is to a great extent unavoidable, there is often not a passable road of any length in a whole district, even in seasonable rainy weather. In Sylhet particularly, roads are bad, and in many places there are none, notably between S. Sylhet and Sylhet Station, the road stops halfway at Fenchogungee on the Koozwari River. The roads are sometimes very good in the most difficult jungly places where the planters have made them, but through the villages and rice-fields where a perfectly straight road could be easily made: the course of the roads represents a succession of figures like the three sides of a square, and where there are many of these eccentricities, the distance is considerably more than doubled. The reason given for this by those who made the roads is that the Deputy Commissioner decided that the rights of the poor villagers should not be interfered with, and the poor villagers directed the road constructor to these old pieces of rough land which were useless to them, and suggested that these places were just in the line of country, and would make a more desirable course for the Government than a road. After the Chief Commissioner had ridden through one of the main roads, it was straightened in parts and much improved, but other and quite as important roads remain in a condition which is a disgrace to any community attempting civilization. There are, it is said, large sums set aside by the authorities for roads, but even if money were short, there can be no valid reason why they should not be made straight. These eccentric puzzle-shaped roads appear to be peculiar to Sylhet. In Assam, the natural difficulties are very great, but struggles are being made to overcome them, and in some parts of Upper Assam the roads are excellent. The main roads in Cachar are in some places good, but there is much room for improvement generally. Cachar however—thanks to the tea planter—is in this respect far ahead of Sylhet—the older district. The only owing to the energy of the old coffee planters, and to the natural advantages of their being generally a quantity of stone available, the roads are superior to any in the Indian tea districts unless perhaps those of Darjeeling.—*Planters' Gazette*, English paper.

TEA DOCK CHARGES.

It is announced by the Dock Companies of London that they will, after the 1st July, allow no discount off their import charges on Tea, but fix a net rate from which there will be no abatement. The Wharfingers have also agreed between themselves and with the Dock Companies that they will only allow a uniform discount of 10 per cent off the latter's charges. This return to the system, of having a fixed scale of charges which is known to everyone, is highly satisfactory. It is to be hoped that the Dock Companies will have the courage to return to their former system of fixed and open rates on all other goods as well as Tea, for in some commodities the so-called "discounts" are simply ruining the trade of London, and driving it to other ports. There is one important grievance which has long called for removal, which the change announced by the Dock Companies does not touch. Some years back, before the discount system was commenced, the Dock labourer struck for higher wages, which were granted by their employers, and made up for by extra charges imposed upon the home trade. The rise in the rates was supposed to be 25 per cent, but in many cases they were actually double. No part of the burden was placed upon the importers, who, on the contrary (when wages, as they soon did, fell to their previous point), were gradually relieved of one-third to one-half of the charges they previously paid.

The abolition of the discount system affords an opportunity for the home trade to insist upon a return to the previous rates, and to call for a general revision of the system of charges. The Wholesale Tea Dealers' Association has had this difficult matter in hand for a long time, but there has been no opportunity as yet for bringing things to an issue. It is in some respects a misfortune that the directors of the two chief Dock Companies, though they number between them no less than eighty-two, should represent the importing interest almost exclusively, under the idea that that alone can "influence business," as it is called—that is, cause goods to be stored at the Docks. This notion may have much to recommend it from the point of view of the Dock shareholders, but in the long run their interest is coincident with that of the home distributors and the public. In trades in which other ports compete, the business, if the charges are too high, would leave London, and in those where there is practically no competition, as is the case with Tea, the rates, through the absence of fresh views and discussion, become stereotyped, and the trade is burdened with unnecessary payments and with an antiquated system of warrants and weight-notes that add enormously to the cost of carrying it on. The result is that Tea is stored for the shortest possible period in the docks and wharves, and that all sorts of expedients are resorted to, to minimise the charges. Amongst others, it has been found advantageous to remove large quantities of Teas under bond at prompt, to the warehouses of a Wharfinger, whose home charges are more reasonable. It might be thought that the preponderating influence of the importing interest in arranging dock and wharf charges would ensure low rates in those items which the merchants have to bear. This, however, is not the case in Tea, where the importers have to pay treble the charges levied on similar produce, such as Coffee and Cocoa. Yet the docks and wharves state that the charges on Tea last year landed them in loss. The explanation of this is to be found in the totally unnecessary amount of detail work in the Tea trade. It has been shown (P.M.R., vol. xiv, page 76) that about thirty separate operations are necessary before a chest of Tea can be delivered, owing to the complications of the weight-note and warrant system.

The Tea trade have been protesting for years past against the oppressive charges with which they are saddled; but their protests are of no avail, though with sufficient union nothing could be easier than to bring about a revision of charges which should be fair to all parties. The Dock Companies and Wharfingers could be first of all approached with a request for a return to the old home trade rates on Tea, now that so much will be gained in the import charges by the abolition of the discount system. If this request were rejected, and sufficient unanimity was found to exist, further steps could be taken. A large body with the most diverse views is never likely to act together, except on points that are clearly reasonable; but in his case the interests of sellers and buyers are really identical. Why should Tea pay three times the import charges on Coffee, unless it be because the former trade is hampered with all sorts of obsolete conditions of working?

The Dock import charges on Tea from the 1st July will be as follows, and the Wharfingers have agreed not to allow more than 10 per cent discount off them:—

For Package weighing Gross.

ENSILAGE EXPERIMENT IN DENBIGHSHIRE.

To Mr. Andrew Murray, Furnace Farm, R.S.O., Denbighshire, we are indebted for the following description of a silo invented and patented by Mr. McIntyre, agent on Lad. Wyloughby's Gwydyr estate, which is believed to be unparalleled in construction:—

So far as the walls and floor are concerned no special noticed necessary, as they are simply the walls of an old barn or stable lined inside with a thick coating of cement. The unique and ingenious part of the arrangement is that the weighting apparatus serves the double purpose of roof as well as pressing the silage. This is accomplished by means of open water tanks, made of wood and lined with zinc. The tanks are suspended by chains, which pass over pulleys fixed in iron standards resting on the wall, and which rise sufficiently high above the level of the walls to allow the tanks to be drawn up so high that they in no way interfere with the filling of the silo. To the ends of the chains passing over the pulleys, and on the outside of the wall, are attached small water-tight boxes. These are so adjusted that two boxes—one each end of the tank—when full of water balance the large tank when empty. Provision is made for the tanks to be kept in their places when moving up and down, so that they don't come in contact with each other nor with the walls. There is also a simple and efficacious arrangement for preventing rain water from getting down the sides of the tanks, and is, I believe, thoroughly effective.

The present method of drawing off the water when the tanks have to be lifted is by a neatly constructed syphon, but I understand Mr. McIntyre has under contemplation an arrangement on the double-pulley system, which will render it quite unnecessary to run off any water. The silo is 14 feet square, and two tanks cover it. The tanks are by no means cumbersome large. It is found that 2 cubic feet of water, in addition to the weight of the tank, is sufficient for each square foot of silage to be pressed. The whole thing is constructed with a considerable amount of skill, forthought, and ingenuity, and is unquestionably a credit to the inventor.

I am sorry I cannot give details as to cost of construction, but it seems to me that where water can be taken to the silo by gravitation, the outlay would be small in comparison to that for an ordinary roof and any of the more common weighting appliances. The silo was empty when I saw it; but I had the pleasure of examining a sample of silage from it some months ago, which was really of excellent quality. I am assured there was not a particle of waste at the sides or top. This is more than we have been able to attain in either of our silos.—*North British Agriculturist.*

A SKILFUL SURGICAL OPERATION.

THE American Ambassador at Vienna, Mr. Kasson, has lately forwarded to his Government an interesting account of a remarkable surgical operation lately performed by Professor Billroth, of Vienna, which, wonderful to tell, consisted in the removal of a portion of the human stomach, involving nearly one-third of the organ—and, strange to say, the patient recovered—the only successful operation of the kind ever performed. The disease for which this operation was performed was cancer of the stomach, attended with the following symptoms:—The appetite is quite poor. There is a peculiar indigestible distension in the stomach, a feeling that has been described as a faint "all gone" sensation; a sticky slimy colic about the teeth, especially in the morning accompanied by an unpleasant taste. Food fails to satisfy this peculiar faint sensation; but, on the contrary, it appears to aggravate the feeling. The eyes are sunken, tinged with yellow; the hands and feet become cold and sticky—a cold perspiration. The sufferer feels tired all the time, and sleep does not seem to give rest. After a time the patient becomes nervous and irritable, gloomy, his mind filled with evil forebodings. When rising suddenly from a recumbent position there is a dizziness, a whistling sensation, and he is obliged to grasp something firm to keep from falling. The bowels costive, the skin dry and hot at times; the blood becoming thick and stagnant, and does not circulate properly. After a time the patient spits up food soon after eating, sometimes in a sour and tormented condition, sometimes sweetish to the taste. Often-times there is a palpitation of the heart, and the patient fears he may have heart-disease. Towards the last the patient is unable to retain any food whatever, as the opening in the intestines becomes closed, or nearly so. Although this disease is indeed alarming, sufferers with the above-named symptoms should not feel nervous, for nine hundred and ninety-nine cases out of a thousand have no cause, but simply dyspepsia, a disease easily removed if treated in a proper manner. The safest and best remedy for the disease is Seigel's Curative Syrup, a vegetable preparation sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White (Limited), 17, Farringdon-road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

ST. MARK-STREET, PETERBOROUGH.

November 29th, 1881.

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years

with dyspepsia; but after a few doses of the Syrup, I found relief and after taking two bottles of it I feel quite cured.

Mr. A. J. WHITE.

I am, Sir, yours truly,

WILLIAM BRENT.

September 8th, 1883.

Dear Sir,—I find the sale of Seigel's Syrup steadily increasing. All who have tried it speak very highly of its medicinal virtues; one customer described it as a "Godsend to dyspeptic people." I always recommend it with confidence.—Faithfully yours,

(Sd.) VINCENT A. WILES,

To Mr. A. J. WHITE, Chemist-Dentist, Merthyr Tydvil, Seigel's Operating Pills are the best family physic that has yet been discovered. They cleanse the bowels from all irritating substances, and leave them in a healthy condition. They cure constipation.

Preston, Sept. 21st, 1883.

My dear Sir,—Your Syrup and Pills are still very popular with my customers, many saying they are the best family medicines possible.

The other day a customer came for two bottles of Syrup and said "Mother Seigel" had saved the life of his wife, and he added, "one of these bottles I am sending fifteen miles away to a friend who is very ill. I have much faith in it."

The sale keeps up wonderfully, in fact, one would fancy almost that the people were beginning to breakfast, dine, and sup on Mother Seigel's Syrup, the demand is so constant and the satisfaction so great.

I am, dear Sir, yours faithfully,

(Signed) W. BOWKER.

To A. J. WHITE, Esq.

Spanish Town, Jamaica, West Indies, October 24, 1882.

Dear Sir,—I write to inform you that I have derived great benefit from "Seigel's Syrup." For some years I have suffered from liver complaint, with its many and varied concomitant evils, so that my life was a perpetual misery. Twelve months ago I was induced to try Seigel's Syrup, and although rather sceptical, having tried so many reputed infallible remedies, I determined to give it at least a fair trial. In two or three days I felt considerably better, and now at the end of twelve months (having continued taking it), I am glad to say that I am a different being altogether. It is said of certain pills that they "come as a boon and a blessing to men," and I have no reason to doubt the truthfulness of the statement. I can truly say, however, that Seigel's Syrup has come as a "boon and a blessing" to me. I have recommended it to several fellow-sufferers from this distressing complaint, and their testimony is quite in accordance with my own. Gratitude

for the benefit I have derived from the excellent preparation, prompts me to furnish you with this unsolicited testimonial.

I am, dear Sir,

Yours ever gratefully,

(Signed)

CARL H. BAKER,

Deputy Missionary,

Hensingham, Whitehaven, October 16, 1882.

Mr. A. J. WHITE.—Dear Sir,—I was for some time afflicted with piles, and was advised to give Mother Seigel's Syrup a trial, which I did. I am now happy to state that it has restored me to complete health.—I remain, yours respectfully,

(C.)

(Signed) JOHN H. LISTER.

HOLLOWAY'S PILLS.—Sleeplessness, flatulency, acidity, nausea, and all dyspeptic indications may be speedily relieved by these famous Pills, of which large quantities are shipped to all parts of the world. The constantly increasing demand for Holloway's medicine proves its power over disease, and its estimation by the public. In weakness of the stomach, in diseases of the liver, and in disorders of the system caused by cold or a sluggish circulation, no medicine is so efficacious, no remedy so rapid, as these Pills, which are altogether incapable of doing mischief. By quickening digestion, they give refreshing sleep, sharpen the appetite, impart tone to the digestive organs, purify and enrich the blood, regulate the secretions, and strengthen the whole physical frame.

FOR PRICKLY HEAT, CONSTIPATION, HEADACHE, BILIOUSNESS, CHOLERA, FEVERS, &c.

The testimony of Medical gentlemen has been accumulated in praise of

LAMPLOUGH'S PYRETIC SALINE,

As possessing elements most essential for the restoration and maintenance of health with perfect vigour of body and mind.

It is Effervescent & Tasteless; forming a most invigorating, Vitalising & Refreshing Beverage.

Gives instant relief in HEADACHE, SEA or BILIOUS SICKNESS, CONSTIPATION, INDIGESTION, LASSITUDE, HEARTBURN, and FEVERISH COLDS; prevents and quickly cures the worst forms of TYPHUS, SCARLET, JUNGLE, and other FEVERS, SMALLPOX, MEASLES, and ERUPTIVE or SKIN COMPLAINTS, and various other altered conditions of the Blood. A valuable PREVENTIVE OF DYSENTERY.

Dr. FROHNE.—"Unfolding germ of immense benefit to mankind."

Dr. BOGGA.—"It furnishes the blood with its lost saline constituents."

GOVERNMENT OFFICIALS AND PLANTERS caring for the welfare of their employes should note its value as a specific in Fever Cases.

Dr. J. W. DOWLING.—"I used it in the treatment of forty-two cases of Yellow Fever and am happy to state I never lost a single case."

Dr. W. STEVENS.—"Since its introduction the Fatal West India Fevers are deprived of their terrors."

HIS MAJESTY'S REPRESENTATIVE the GOVERNOR OF SIERRA LEONE, in a letter of request for an additional supply of the Pyretic Saline, writes, "It is of great value, and I shall rejoice to have it in the hands of all Europeans visiting the Tropics."

To be obtained of any Chemist or Drug Store, in Patent Glass-stoppered Bottles, at various prices.

Please note in connection with the recently observed effects of the use of Citrate and other preparations of Magnesia that LAMPLOUGH'S PYRETIC SALINE is warranted not to contain Magnesia or any substance which would cause calculous or other earthy deposits.

H. LAMPLOUGH, 113, HOLBORN HILL, LONDON, E.C.

HEALTH FOR ALL!!!

HOLLOWAY'S PILLS & OINTMENT

THE PILLS

Purify the Blood, correct all Disorders of the

LIVER, STOMACH, KIDNEYS, AND BOWELS.

They invigorate and restore to health Debilitated Constitutions, and are invaluable in all Complaints incidental to Females of all ages. For Children and the aged they are priceless.

THE OINTMENT

Is an infallible remedy for Bad Legs, Bad Breasts, Old Wounds, Sores and Ulcers.

It is famous for Gout and Rheumatism. For disorders of the Chest it has no equal.

FOR SORE-THROATS, BRONCHITIS, COUGHS, COLDS,

Glandular Swellings, and All Skin Diseases, it has no rival; and for contracted and stiff joints, it acts like a charm.

Manufactured only at THOMAS HOLLOWAY'S Establishment,

78, NEW OXFORD STREET (late 533, OXFORD STREET), LONDON,

And are sold at 1s. 1½d., 2s. 9d., 4s. 6d., 11s., 22s., and 33s. each Box or Pot, and may be had of all Medicine Vendors throughout the World.

See Purchasers should look to the Label on the Pots and Boxes. If the address is not 533 Oxford Street London, they are spurious.

INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA :—SATURDAY, AUGUST 29, 1885.

[No. 35.]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING AUGUST 19, 1885.]

General Remarks.—Rain has fallen during the week in all districts of the Madras presidency from which reports are received. In Bellary heavy rain is urgently required for the early dry crops. Prospects are still unsatisfactory in Madura, and more rain is wanted in Tanjore, Coimbatore and Tanjore. Elsewhere prospects are generally good, and improvement has taken place in Anantapore. In Mysore very slight rain has fallen, the crops are in a critical condition, and pasturage and water are failing. In Coorg prospects continue good.

Prospects have greatly improved in the Bombay presidency, in consequence of the recent rainfall, but more rain is urgently wanted in parts of Sholapore and Bijapore. In these districts and in Nasik, Poona, and Ahmednugger fodder is scarce. *Kharif* sowings are still in progress in places. Rain has fallen in the Berar and Hyderabad, and the condition of the crop is favourable. In the Central India and Rajputana States rain has been general, and the crops are generally in a satisfactory condition.

Good rain is reported to have fallen throughout the Punjab, with the exception of the Lahore district. *Kharif* prospects are generally favourable. Rain has fallen in most districts in the North-Western Provinces and Oudh, and a break is now wanted. Crop prospects are good, though some damage has been caused to cotton, indigo, and the crops on low lands. Rain has been general in the Central Provinces, and prospects are good.

In Bengal rain has been fairly general, but more is wanted in some districts. Early crops are generally doing well, but in some places in Behar and the Burdwan divisions and in Moorsheda bad injury has been caused by floods. The *aus* rice harvest is progressing, with prospects of a fair average outturn; and *aman* rice is being transplanted. Seasonable weather prevails in Assam, but in Sylhet more rain is much needed for the paddy crop on high lands. Transplanting continues.

In British Burmah the rains have been seasonable in all districts, except Prome, where more rain is required. Ploughing, sowing, and transplanting are in progress.

The public health is generally fair.

Prices are fluctuating in the Punjab, and have risen slightly in Mysore. Elsewhere they are fairly steady.

Madras.—General prospects fair, improved in Anantapore; in Bellary early dry crops will be lost if heavy rain does not fall soon; in Madura reported to be discouraging.

Bombay.—Good rain throughout the presidency. General prospects greatly improved. More rain urgently wanted in parts of Sholapore and Bijapore. Crops injured by insects in parts of Kurrachee, Hyderabad, and Upper Sind Frontier; scarcity of fodder in parts of Nasik, Poona, Ahmednugger, Sholapore, and Bijapore, and of water in parts of Sholapore. Cholera in parts of eighteen, fever in parts of nine, cattle-disease in parts of seven, and small-pox in parts of three districts.

Bengal.—Rain has been fairly general in all districts, more rain is wanted in some districts. Early crops are generally doing well, but in some places in Behar and the Burdwan divisions and in Moorsheda bad, they have suffered from floods; *aus* rice harvest is progressing, with prospect of a fair average outturn; transplanting of *aman* rice still proceeding. Price of rice continues high. General health not so satisfactory as before, fever and cholera being prevalent in many places.

N. W. Provinces and Oudh.—Rain has been pretty general during the week, and a break is now needed. Prospects are good, though some damage has been caused to cotton, indigo, and crops on low lands. Markets well supplied, and prices generally steady. Public health fair; cases of cholera reported from a few districts.

Punjab.—Good rain throughout the province, with the exception of the Lahore district. Health good. *Kharif* prospects generally favourable. Prices falling in the Delhi and Peshawar districts, rising in the Ferozepore, Halkot, Mooltan and Rawul Pindie districts, and generally stationary elsewhere.

Central Provinces.—Weather alternately clear and wet. Weeding continues; prospects of crops favourable. Cholera in Raipore; elsewhere health generally good. Prices steady.

British Burmah.—Cholera prevalent in one district, slight in four districts; small-pox slight in one district, elsewhere public health good; cattle-disease somewhat prevalent in one district, slight in three districts, elsewhere health of cattle good. Ploughing, sowing, and transplanting progressing. Rains seasonable in all districts, except Prome, where more rain is required.

Adam.—Weather warm. Reaping of *damah* and *owall* crops nearly finished; transplanting of *sali* crops in progress. Common rice 18 annas per rupee. Prospects of tea good. Health good.

Mysore and Coorg.—Rain needed everywhere and specially in parts of south-eastern Kolar, Northern Tumkur and Chitaldroog, and north-eastern of Mysore, where unless timely fall occurs, the young dry crops which are the staple of the country will die; they are reported to be withering in some quarters and to be in a critical condition in others; cattle-disease reported in parts of Bangalore. Pasturage falling and water-supply scanty. Crops in good condition. Price of food-grains has slightly risen. Prospects of season and public health good.

Berar and Hyderabad.—Rain very beneficial to standing crops. *Abi* sowings progressing. Cholera still prevails in the city and suburbs and at Seram, but general health in the districts good.

Central India States.—A break in rains desirable. Health good. Prices stationary. Weather very hot, with thunderstorms and occasional showers. 15 deaths from cholera in Sewri, 2 or 3 deaths daily in Bhopal. Prospects of crops unfavourable.

Rajputana.—Tanks and wells full. Crop prospects good. Health good. Prices steady.

Nepal.—Prospects good. Cholera continues.

Letters to the Editor.

PROGRESSIVE RATES.

TO THE EDITOR.

SIR,—I do not think short leases are good for tenants, as it keeps up their anxiety as to the terms on which the next settlement will be made. At the same time a long lease involves in newly settled countries a wanton sacrifice of revenue. I shall give you an instance: Baminghattie has never been surveyed before. The ryots are paying now at the rate of about 5 annas 6 pias per man of 22,500 sq. ft. per man. A short lease will displease the people, as the visit of the Amee is most dreaded. You cannot treble or make fourfold the present rates. The case of the Central Provinces is probably on a larger scale than that of Baminghattie. What do you think of progressive rates? I shall suppose that the rate in the Central Provinces is 4 annas per bigha now, and the fair rate would be 12 annas. In that case, why not grant a lease of 30 years, but make the rates progressive, say 8 annas for the first ten years, 10 annas for the next ten years, and 12 annas for the last ten years. Progressive rates have been adopted in the case of the waste lands that are granted in Assam to tea planters. I see no reason why they should not be granted to ordinary ryots. Hoping to hear what you have to say against progressive rates,

S. DUTTA.

Settlement Officer in Moorshad.

P.S.—Do you know of any province where progressive rates have been granted to ordinary ryots?—S. D.

NOTE.—We believe that progressive rates are unknown in India, so as we are aware; but we should be glad to have any information on subject. We are in favour of progressive rates, although we do not approve of very long leases.—ED., 1, A.

Editorial Notes.

A REPORT from north Borneo says that gold in paying quantities has been found in the bed of the Segama river. Samples had been sent to Hongkong, which, on analysis, gave excellent results, and a company is to be formed to work the mines.

The quantity of tea exported from China and Japan to Great Britain, from the commencement of the season to the 30th of July last, was 69,119,482 lbs., as compared with 70,508,682 lbs. exported in the corresponding period of last year. The exports to the United States and Canada during the same period were 20,967,321 lbs. as against 21,824,526 lbs.

A VERY thoughtful article recently appeared in the columns of the *Indian Mirror*, "On the necessity of Improved Tillage in Bengal," which we reproduce elsewhere. The subject of improved agriculture is come to be recognised as one of paramount importance, and we are glad to see such a journal as the *Indian Mirror* taking up the subject with such earnestness.

A CORRESPONDENT from Bhagulpore writes to the *Statesman* that a project to start a sugar manufactory, and in connection with it, a rum distillery, is on the tapis there among the mercantile community. A native gentleman, who has had considerable experience in the distillery business, is prepared to take the management of such a concern, and to invest a considerable amount of capital in the venture.

We have been favoured with the first three numbers of the *Journal of the Agricultural Students' Association*, for the months of April, May, and June 1885, which is published at Madras. We have no hesitation in saying that it is likely to do much good to the cause of agriculture in India. The *Journal* contains some good articles and well-selected papers from high-class publications devoted to agricultural subjects. We congratulate the promoters, and hope they will achieve the success they deserve.

THE introduction and cultivation of the cocoa tree in Singapore have given satisfactory results; for from the last report of the Botanical Gardens there, it appears that Mr. Cantley, the Superintendent, has been trying to acclimatise this tree for some time, and has succeeded in his efforts. We are told that it has not only flowered, but has fruited freely during the year. This ought to be good news to the planters on the island, as opening up a field for a new industry. They will no doubt think it worth their while to undertake further experiments with this plant.

LAST week we drew attention to the mining industries in Burmah. We now learn that it is proposed to start a limited liability company in London, to be called the British Burmah Lead Company, for the purpose of working the lead mines in Burmah. The province is rich in minerals, and needs only capital and energy to bring its resources within reach of the trade. We hope the example of this new company will soon be followed by others to work the iron, tin, and coal mines. There is also earth-oil, with antimony and galena: these are all worth working.

A CONTEMPORARY has received a letter from Kumaon, dated 10th instant, which says that the rainfall since the beginning of the month had been unusually heavy for August, bringing the total fall this season up to 33 inches. The rice crop was good, but millet and *blat*, a species of pulse, were failures. Tea-making was actively progressing, but it was not expected that more than 100,000 lbs. of green tea, if so much, would be

made for the Central Asian market, the uncertainty of our relations with Russia having alarmed the native merchants. A good deal of tea made in the district is now sent to the Kotlogodan station of the Rohilkund and Kumaon Railway, instead of by the old circuitous route *via* Almorah or Ranikhet to Moradabad, a great saving in transit charges being thus effected.

COLONEL ROGERS, the Superintendent, Madras Survey, has very properly pointed out to the Government the incongruity of demarcating and surveying unassessed waste in a district in which field demarcation does not exist, as is the case in the Godavery district, and that the operation cannot, any way, be undertaken before the next official year 1886-87, by the party No. 1, which is engaged upon important topographical and revenue survey now. Colonel Rogers observes, with perfect truth, that, the experience of the department has always shown that it is more economical, and in every way far more satisfactory, to employ a strong party under the best supervision, and to finish a work quickly, than to entrust it to a small party under subordinate supervision, and allow it to extend over a long period." And the wonder is that this should not have occurred to the Government of Madras!

PUMPKINS are spoken of as something new in the way of food for horses. One writer, addressing himself to an Australian paper, says:—"I consider pumpkins a first-rate winter feed, keeping the bowels open and giving a gloss to the coat. It is very hard to get horses to take to them. I have tried almost every way I could think of—chopped the pumpkins up and given it with chaff and corn, put salt into the nose-bags, boiled it—to no purpose. We had a good supply last winter, and tried to feed our horses on it, but they would not touch it. The only way is to get a horse which has been fed on pumpkins, and let him go with your horses. When once a horse takes to them, he becomes very fond of this feed. For feeding prize stock, they are of great value. One boiled pumpkin is worth two uncooked ones." This is certainly not encouraging, but if the vegetable really possesses the good qualities ascribed to it, an attempt should be made to use it largely.

THE ryots of the Anantapore district do not seem to have appreciated the "benevolent objects" of the Government in sending a boring party among them to strike water when there was such a scarcity of this fluid in those parts, for the officer in charge of the party of Sappers and Miners sent to bore wells, in submitting his report, says:—"Since these boring operations have been carried out, in no single instance, it is believed, have any one of the proprietors attempted to open out a well of any description, nor have they shown any personal interest in the matter, but rather have been unwilling to point where they would wish the borings to be made in their respective properties, when called upon to do so. This apathy on their part is much to be deplored, for the expenditure incurred is very considerable, even after deducting the value of the tools and plant, but it was conjectured, at the outset, that the ryots anticipated advances being made to them which they could turn to account or not as they thought fit." It seems that water was struck at moderate depths; but, on the whole, the success of the experiment was of a negative kind, and the Madras Government have pronounced the deputation of trained boring parties as premature until such time as the means of protection from drought have been fairly started by the construction of a few wells.

THE following is a summary of Messrs. William James and Henry Thompson's fortnightly Circular of Indian Tea, dated London, 30th July 1885:—"Upwards of 22,000 packages have been catalogued for sale during the fortnight, including 11,300 new season's, 8,500 from Ceylon, and 4,000 of old season's tea. There has not yet been sufficient recovery in demand from the country to give life to the market, and the sales have passed with a dull tone. During last week quotations were very weak

and irregular, showing in most cases a decline of 1d. to 2d. upon Pekoes and Broken Pekoes, and 1d. upon Soucheongs and Broken. This week the market has been steadier, with rather firmer rates for low-priced teas. The large supplies from Ceylon have sold freely, but the previous range of price has not been maintained, except for the finest qualities. From Calcutta, we learn that about 20,000 packages were sold at the sales of the 16th and 23rd instant at an average of 10½ annas, a reduction of 1½ to 1½ annas upon the previous quotations. To-day about 13,000 packages are offered, and lower prices are quoted in the telegrams. The exports to the 4th instant were 5,000,000 lbs., as compared with 3,600,000 lbs. last season. The next auctions here take place on the 5th August.

**

The returns of railway-borne traffic in the Central Provinces, during the quarter ending 31st March 1885, show that the traffic of the quarter under notice, while almost equalling that of both the preceding quarters taken together, falls considerably short of that of the first quarter of the year. But this is to be expected, as the months immediately following *rabi* harvest, which fall in the first quarter of the year, are, as a rule, more brisk in traffic. The gross traffic of the quarter, as compared with the three preceding quarters, is as follows:—

	Imports.	Exports.
	Maunds.	Maunds.
Ending 30th June 1884 ...	9,40,000	65,78,000
„ 30th Sept. „ ...	3,02,000	20,36,000
„ 31st Dec. „ ...	5,67,000	31,53,000
„ 31st March 1885 ...	7,23,000	48,75,000

Of the imports, the principal items were—

Salt ...	2,74,948 mds., or 38 per cent.
Sugar ...	1,74,921 „ „ 24 „ „
Metals ...	61,547 „ „ 8 „ „

Cotton goods—34,543 maunds, or 5 per cent.

Practically, the whole of the salt, and 80 per cent of the fine sugar imported, came from Bombay. But 80 per cent of the total sugar imports consisted of the coarse compost known as *gour*, and for this the North-Western Provinces and Bengal were drawn upon. The metals and cotton goods were principally derived from Bombay, being for the most part European goods imported *via* the Bombay Port.

**

Of the total exports, the principal items were—

	Maunds.
Coal ...	5,38,590, or 11 per cent.
Wheat ...	24,54,160 „ 52 „ „
Rice ...	6,09,000 „ 125 „ „
Grain ...	2,08,027 „ 4 „ „
Linseed ...	6,41,626 „ 13 „ „
Tilseed ...	1,48,041 „ 3 „ „
Hides ...	27,033 „ 0.5 „ „

From the foregoing figures it will be seen that wheat constituted more than half of the export trade. It was, practically speaking, all consigned to Bombay and the Nerbudda block, including the districts of Narsingpore and Hoshungabad. The quantities consigned from the Jubbulpore, Nagpore, and Chutisgarh blocks amounted respectively to 2½, 2½, and 2 lakhs of maunds, while the amount exported from the Nerbudda block reached the high figure of 17 lakhs of maunds. The rice was consigned partly to Bombay, and partly to places in the Berar and Bombay Presidency, and was produced chiefly in the Chutisgarh division. The linseed was taken by Bombay, Chutisgarh supplying nearly half the quantity exported, and the Nagpore block, the greater part of the remainder. More than half the quantity of hides exported was also contributed by Chutisgarh, which was due to the great mortality amongst the cattle of that tract during the preceding rains.

**

Mr. Bosworth Smith, the Government Mineralogist, Madras, has been prosecuting his explorations with much assiduity. His

experiments with galena and pyrites are likely to throw some light upon the question as to how the gold occurs in these ores. He has been examining the workings of the Ilitara Gold Mines, and finds that the minerals that occur there are copper pyrites and galena, deposited mostly in the central portion of the reef. In a piece of quartz that he picked up, he found a little calcite, but there was no gold visible, and very little iron pyrites. He gives the method adopted at the mine of extracting the precious metal from quartz, and estimates the outturn at 8 grains of gold per ton of quartz. The cost of extraction was found to be Rs. 40-12 per ton of quartz, and the gold extracted fetched Rs. 300 per ounce. The manager of the mine estimates that if the quartz would yield 3 dwts. per ton, the ore would just pay expenses. He attributes the cause of failure to the “sickening” of the mercury preventing the gold from forming an amalgam, but adds that, even if this were prevented, it by no means follows that amalgamation is the best process for the ore; the gold being, he believes, if free, in too fine a state of division; and if occurring in the galena and copper pyrites, in a totally unfit state for this process. There cannot be any doubt that Mr. Bosworth Smith is the right man in the right place. His diaries display a mastery of the subject in hand; and if the Southern Presidency possesses any minerals of value, they will doubtless be brought to light in due course.

We have before us the report of the Director of Agriculture and Commerce, N.-W. Provinces and Oudh, on the ensilage experiments carried out last year at the Cawnpore Agricultural Station. We give the report, which is a brief one, in the Director's own words:—“Between the months of September and December of last year, 13 pits were filled with fodder for ensilage; 3 of these were old masonry pits built some years ago in connection with a scheme for subsoil drainage, and the remaining 10 were merely holes of various sizes and shapes, especially dug for the purpose in a plot of elevated ground. Over 7 of the 10 pits thus dug, cheap straw thatchings were placed for protection. The other 3 pits were protected by tile roof, and covered over by conical mounds of earth to a height of from 3 to 4 feet. Juar, sorghum, dub grass, and guinea grass were the fodders ensilaged. A small portion of the juar had been cut in flower, but the greater part of it after the grain had got well on towards ripening. The other crops were cut when in flower. The silos were filled gradually in layers, two days being generally allowed to intervene between the successive fittings. On the opening of the pits, it was invariably found that, with the exception of the mouldy crust of about six inches thickness on the top and round the sides, the fodder had been well preserved, and was freely eaten by cattle.”

**

The total cost of the 13 silos amounted to Rs. 304, the lowest cost of one being Rs. 2-1, and the highest Rs. 130-12. The total amount of fodder silaged weighed 4,967 maunds. The smallest silo contained 61 maunds, and the largest 1,833 maunds. The largest silo, which was elliptical, measured 30' x 18' x 13' and the smallest, which was circular, 6' x 10'. They were all filled between September and December 1884, and opened between February and June 1885, or on an average of five months after closing. We should have liked to have known whether the silage produced was sweet or sour in quality, whether any record was kept of the temperature of each silo, and whether there were any signs of the bacteria of fermentation in the silage when opened. Also whether, after having been opened for several days, there was any change in the quality of the silage, and whether cattle and horses partook of it as readily as when the silos were first opened. Without such particulars, it seems to us a waste of time, labour, and money to construct silos and store fodder. The system of ensilage is in its experimental stage at present, and it was, we presume, with a view to ascertain the advantages, of otherwise of the system that the Government of India sanctioned experiments to be conducted. We hope that Government officials making silos will take note of these remarks.

THERE has been a good deal of discussion lately about the retention or otherwise of Rule 7 of the Madras Forest Act as it at present stands. Some doubts having arisen as to the precise application of this rule, the two Conservators of Forest were called upon to give their opinion, as it was thought that the rule bore with undue severity upon the poorer classes. Both the Conservators are, however, opposed to any radical alteration in the rules until experience has shewn such to be necessary. At the same time they admit that in certain cases the rules as they stand at present bear hardly on the poorer classes, but they are at one in their desire to retain Rule 7 substantially as at present, and to carry it into effect without delay. The Board of Revenue, on the other hand, are prepared to concede the privileges in question not only to ryots, but to all villagers, "without any check or hindrance by village heads." With such variable opinion to go upon, the Madras Government have very naturally been placed in a somewhat difficult position; but on further consideration, they are of opinion that it will be better for the present at least to retain Rule 7 substantially as it stands, but to alter it in some respects to meet the views of the Board of Revenue; so that the much-vexed rule, as amended, will run as follows:—

"Where the practice of grazing cattle, sheep or goats, or of cutting trees (other than reserved trees) or other forest produce for fuel, or for building, agricultural, or domestic purposes, or of cutting grass for thatching or fodder, or thorns for fences or leaves of trees (other than reserved trees) for manure, free of charge, has long and steadily obtained, the Collector shall set apart once for all such areas as he may consider reasonable for this purpose, and shall, &c., &c." (as at present.)

Although this amendment does not meet all the requirements of the case, it goes far towards reducing the severity of the rule as bearing on the poorer classes.

We learn that manufacture is now finished at most of the indigo concerns in Lower Bengal, and though details have not yet been furnished, the estimated outturn is about 20,000 maunds. Very heavy rain fell over nearly the whole of Behar, between the 6th and 13th instant, which somewhat reduced the produce, and the result of the first cuttings (which are now nearly all worked off), is estimated at 37,000 maunds, or about the same as last year. The heavy rain seriously damaged the *Khoontees* in some of the lowlying lands, and unless there is very favourable weather during the rest of the season, they are hardly likely to realise a fair return. *Khoontee Mahvi* will commence early in September. The reports from Benares and the North-Western Provinces continue unfavourable, the plant being small and backward, and the yield very poor. The area under cultivation is smaller than that of last year, the weather throughout has been most unfavourable, and there is now no doubt that the outturn will be less than that of last season.

A CORRESPONDENT of the *Statesman*, writing from Rajmehal, under date the 18th instant, says:—"Mr. S. Sakhawat Hossein came here on the 13th instant to make enquiries into the native mode of agriculture, and try some experiments, and to teach us how to improve our farm. He has also given us to understand the advisability of ensilaging the *makai* stalks, the grain of which we cannot reap owing to the inundation. He has constructed here a silo for ensilaging grasses, and if this succeeds, we shall one and all adopt this method of storing our green fodder for cattle." It is gratifying to learn that members of the Agricultural Department of Bengal are taking the right steps to spread a knowledge of high-class agriculture among the people of the outlying districts. It is only by going among them, and enquiring into their methods of farming, and by suggesting improved methods, that the cultivators can be taught to introduce innovations which they would otherwise regard as dangerous and expensive.

We have received a little pamphlet of 32 pages, entitled a "Catechism on Soils and their Improvement," by M. Bhavani Shanker Ray. The author has given us a very interesting

little treatise on a very important subject, and has handled the matter in quite a practical manner. The little pamphlet before us contains much useful information, and is likely to produce good effects if placed in the hands of landlords and cultivators, by giving them sound answers to practical questions. To attain the object in view, it should be translated into the vernacular, when it will be better understood by the masses for whose benefit the catechism is presumably written. The author intends to follow this up by two other similar pamphlets, one on the *Staple Products* of the Madras Presidency, the other on *Live Stock and its Management*. He deserves encouragement in his undertaking; and we hope he will receive active support in his endeavours to "diffuse a sound and precise knowledge of the elementary principles that underlie the successful cultivation of soil." It is gratifying to see native efforts put forward in this direction.

THE much-talked-of Veterinary College and Hospital at Bombay has been shelved for the present financial year, and the decision of the Governor of Bombay on the subject has been communicated to the Bombay Society for the Prevention of Cruelty to Animals in the following terms, in a letter, dated the 4th instant:—"I am directed to acknowledge the receipt of the petition from the Bombay Society for the Prevention of Cruelty to Animals, dated the 11th ultimo, soliciting a reconsideration of the decision of this Government that the establishment of a veterinary college and hospital at Bombay should be deferred in accordance with the instructions received from the Government of India, to exercise the strictest economy in all departments, and requesting that that much-desired institution may be started at once, after revising, if necessary, the scale of the proposed monthly expenditure. In reply, I am directed to inform you that his Excellency the Governor in Council, whilst taking the warmest interest in the progress of veterinary science, and being most desirous that the Veterinary College and Hospital in Bombay should be established at the earliest practicable date, much regrets that it is at present not possible to follow the course recommended by you for adoption. The Government of India have been informed that the college will not be opened during the current financial year, and that there will consequently be an estimated saving of Rs. 28,000 under this head. In view of the many pressing demands for funds for institutions, such as hospitals for women and children, even more urgently needed than a Veterinary College and Hospital, the Governor in Council feels that it would be impossible to select the latter for exceptional treatment, and whilst refraining from incurring expenditure on objects for the benefit of suffering human beings, to move the Government of India to authorise a special outlay on a veterinary college."

DR. GEORGE WATT, who was applied to by the Government of India to suggest the best method of preparing coca leaves for the market, has referred the Government to Spence's Encyclopaedia as containing the information on the subject. The portion of the work he refers to, runs as follows:—"When ripe, which is known by their cracking or breaking off when bent, the leaves are sun-dried; this operation requiring special care. The green leaves are spread in thin layers on coarse woollen cloths, stretched upon prepared earthen or cement floors, after the manner of the 'barbecues' used in coffee-drying, and exposed to the heat of the sun; when perfectly dry, they are pressed into serons or skin bags. Every precaution must be taken to prevent their imbibing any moisture during exposure, and to ensure their not sweating either then or subsequently. Well-cured leaves are uncured, of a deep green color on the upper surface, and grey-green beneath, with a strong tea-like odour and pleasant pungent taste, and produce a sense of warmth when chewed; inferior ones are dark colored, with a less agreeable samphoraceous smell, and are almost devoid of the pungent flavour and physiological effect." In his opinion the best work dealing with the subject is Gosse's *Monographie de l'Erythroxylon Coca*. Mr. Duthie, Superintendent of the Saharanpore Botanical Gardens, furnishes the following information on the subject:—"Judging

from our mode of proceeding in the case of the henbane plant, of which we prepare annually for the Indian Medical Department both leaves and extract, I should be inclined to recommend as follows:—The young leaves should be plucked as soon as they are fully developed, a sufficient number being left so as not to weaken the bushes too much. The leaves should be gathered and handled with great care, for one of the most important constituents of this plant is an aromatic volatile alkaloid. They should then be spread out on mats and exposed to the sun until they are quite dry. Should the weather be unfavorable for drying the leaves by the heat of the sun, some artificial arrangement must be adopted. The dried leaves should be despatched to the market in tin-lined boxes. I should mention that in Bentley and Trimen's 'Medicinal Plants,' Vol. I, there is an interesting article on the coca plant, together with a colored figure." We may observe here that Dr. Bidie, of Madras, has most courteously placed at our disposal a small quantity of the dried leaves of the coca. We do not know what process he adopted, but the leaves are beautifully dried, and contain all their essential qualities. They have a pungent, aromatic odour, but are tasteless. We are having an analysis of the leaves made, and hope shortly to publish the results.

DR. E. L. CLEAVER has been attempting the manufacture of quinine in India; and to enable him to carry out his experiment, he was supplied with 2,000 lbs. of the red bark by the Government of Madras. Dr. Cleaver succeeded in making three species of alkaloids, viz:—

1. Sulphate of Quinine.
2. Febrifuge.
3. Crystalline Febrifuge.

He says that the "sample of quinine is not quite as white or as silky crystals as Howard's, but is quite equal to many commercial specimens; and, considering the very limited resources I have at my disposal, and the small scale in which it is prepared, it is, I think, a proof that it could be made commercially. It is prepared from red bark, and it is as pure as could be obtained from that kind. The febrifuge, although similar in color to Government preparation, is different in composition. The whole of the alkaloid in it is easily crystallisable, while it is a most difficult matter to crystallise much from the Government febrifuge. The crystalline febrifuge is prepared by simply crystallising No. 2." The Director of Government Cinchona Plantations, Madras, does not quite agree in Dr. Cleaver's conclusions. In reporting upon these alkaloids, he says:—"No. 1, which was forwarded by Dr. Cleaver as being sulphate of quinine, contains no less than 37.90 parts of sulphate of cinchonidine out of 102.07 parts. This large amount of cinchonidine would, in the present dogmatic state of the market, greatly impair the commercial value of this preparation, though, as Mr. Hooper very accurately points out, its medicinal excellence would not be interfered with. Analyses of Dr. Cleaver's sample No. 2 are compared by Mr. Hooper with analyses which he has recently made of samples of febrifuge obtained from the Government laboratory in Sikkim; and from this comparison it will be seen that while Dr. Cleaver's febrifuge contains no quinine, that from the Sikkim laboratory contained 6.97 per cent. On the other hand, Dr. Cleaver's febrifuge contains 35.62 per cent of cinchonidine, while that from the Sikkim laboratory contained only 15.78 per cent. Therapeutically considered, the two febrifuges are probably of equal value. Of Dr. Cleaver's third sample Mr. Hooper says that, 'although labelled crystalline febrifuge, it is really nothing more than an unbleached preparation of quinine and cinchonidine sulphate, almost identical in composition with sample No. 1.' Dr. Cleaver, in his letter to Messrs. Arbuthnot and Co., and also in a letter to myself, states that he has labored under considerable difficulties in manufacturing these febrifuges, owing to his not having received certain necessary chemicals and apparatus. It is therefore to be presumed that, under more favorable circumstances, his account of the composition of the samples which he has sent would have been more exact; and I have no doubt that, if a factory were to be established under his direction, a

febrifuge of a high character might be turned out at a low cost."

These results are satisfactory so far that there were no possibility of manufacturing quinine in India at low cost, or even were it can be obtained from England. It is merely the by-product of proper appliances. The material is at hand fresh, and is that no reason why the sulphate of quinine cannot be manufactured here.

The following is a summary of the weather for July 1885.—Heavy rain fell at Mangalore on the 1st. This proved to be the beginning of a burst of rather heavy rain on the west coast, lasting until the 9th, and spreading northward as far as Rutnagiri without, however, reaching Bombay. Between the 10th and 16th, though rain fell daily along the west coast, the amounts were not large, but on the 17th a fall of six inches occurred at Bombay, and larger amounts on the neighbouring hills. This was the first downpour of the season on the Konkan coast, and resulted in extensive floods in the neighbourhood of Bombay. Rather heavy rain again fell along the Malabar Coast on the 23rd; but, on the whole, the amounts recorded in the west of the peninsula, subsequent to the middle of the month, were moderate, and except in Malabar, the total rainfall of the month was below the average. In Gujarat the rainfall was nearly up to the average of the month, but this result was due rather to the occurrence of heavy local and spasmodic falls at Rajkote, Ahmedabad, and Broach than to steady, continuous rain throughout the month. In Sindh and Cutch and northward over the Punjab there was very little rain, the relative deficiency during the present month being even greater than in those provinces during June. In the central parts of the country, i. e., Rajpootana, Central India and the Central Provinces, though the average was not actually equalled, the deficiency was small, and in the Berars, the Deccan, and Hyderabad, the average was slightly exceeded.

In the eastern and central parts of the peninsula the normal westerly winds appear to have been exceptionally dry; and Mysore, Bellary, and the Carnatic had even less than the small average rainfall. Further north, in the Northern Circars, Orissa, Chota Nagpore, and Lower Bengal, there has also been a slight deficiency; but in Assam, Cachar, Northern Bengal, and over the whole of the North-Western Provinces and Oudh the rainfall has been excessive. During the month several small, and in general feeble, depressions have travelled slowly up the Gangetic plain,—some apparently having been formed over the Gangetic delta, others over Behar or that neighbourhood. Though very slight when measured by barometric differences, some of these disturbances have occasioned heavy falls of rain, of which the more important are as follow:—

	Inches.		Inches.
Darjeeling, 2nd	... 4.38	Dinapore, 12th	... 4.41
Bahraich, 3rd	... 4.02	Sutna, 13th	... 5.01
Mozufferpore, 4th	... 5.20	Aligarh, 16th	... 5.50
Naini Tal, 3rd and 4th	... 14.80	Benares, 22nd	... 4.68
Saugor Island, 7th	... 4.27	Saugor Island, 29th	... 8.15
Bareilly, 11th	... 4.21	Mussorie, 30th	... 5.48

On the whole, the rainfall of the month has been more favorable in many respects than that of June. The Punjab, Sindh, Cutch, the Konkan, and Orissa, again exhibit more or less important deficiencies; but in North Bengal and Behar, where last month a serious deficiency seemed impending, there has now been an almost compensating excess, and in the Deccan, Hyderabad, and Berars, though the excess of the present month does not make up for the deficiency of the last, there has at least been no further failure.

These figures for the season, up to date, show that the rains have been unfavorable in two regions. One includes the Konkan, Khandesh, and the Bombay Deccan, where the amount of rainfall for the two months, June and July, has been only from 1/5 to 1/2 of the average amount, and the other the Punjab, where (though there are some exceptions) the general rainfall of the Province has been only 1/2 to 1/3 of the normal. In all

of the country the seasonal average has been maintained. There has been retention of other elements at present stands. The application of these elements exhibit few variations were called upon. The average has been a pretty general excess of the rule over the peninsula, extending on the western side, Bothward in the Peninsula, and a general deficiency also in Northern and Central India. The temperature has been above the average in the Punjab, the Central Provinces, Central India, Sind, Gujarat, and the Konkan, but generally below it in the peninsula and Burmah. The amount of humidity in the atmosphere has been below the mean in the Punjab, and has varied irregularly elsewhere.

WILD MANGOES.

(By C. MARIES.)

The *jungli am*, which is the original stock of all our fine mangoes, is not often met with in its native habitat, and less frequently in fruit. I have just received a few fine specimens of several varieties of *jungli* mangoes. From the fruits, it appears they vary quite as much as our cultivated ones; and as to shape, they are the exact counterpart in miniature of many of our best varieties. My specimens came from the Kangra valley, and were collected by a gentleman much interested in the fruit. I once saw the true *jungli* mango in the Dooars, and again afterwards growing at an elevation of about 2,000 feet in Sikkim. It is very unlike the cultivated sort, having generally a straight trunk, whitish, smooth bark, and thin leaves, forming a fine, round-headed tree. The fruit rarely weighs 3oz.; often only one 1oz. The common country mango called "Beju" or "Desi," in Tirhoot, is really an inferior kind of cultivated mango, and not the proper wild mango of the forests.

Wild mangoes are found from India through Malay to Manila and some of the Pacific islands, and it is not really known if there is more than one species. The wild and cultivated sorts are so widely different in shape of fruit, that they could almost be called distinct species, but every intermediate connecting stage may be found to bring them under one head. The flowers of the wild and cultivated mango are exactly the same in structure, except that in the wild one there are often more stamens fertile.

It may not be known to most people that generally in a mango flower there is only one stamen out of the lot fertile; this one is curved round just over the pistil in a peculiar way, to facilitate the fertilization. The so called "nak," or nose of the mango, is the place the pistil adhered to in the flower. All this can be plainly seen with a moderately powerful reading glass or lens when the mangoes are in flower.

PROTECTING MANGO FRUIT.

A very good way to protect mangoes from the attacks of birds and insects is get a lot of very finely-woven, round bamboo baskets made, say 4 inches wide at top, 5 inches at the bottom, and as long as may be required for the fruit; see that there is not room for a fly to get in through the basket-work. Then put the mango inside as it hangs on the tree, push a long thin peg through the top of the basket by the side of the stalk of the fruit on one side, and another similar peg on the other side, and the mango will hold the basket up itself; then tie a little calico over the top of the basket, taking care not to tie the mango stalk, and also to completely shut up the top of the basket. The mango stalk must be quite free, because when the fruit is ripe, or nearly so, it will fall of its own accord, and will be found to be just fit to gather. If a net be suspended under the tree, then all danger of bruising the fruit will be avoided. Then shake the tree to gather only the ripe ones. These should be kept on a "machan" for a few days till quite ripe, as all mangoes improve by keeping a little, and should never be eaten perfectly fresh from the tree.

CATTLE-DISEASE IN THE AMHERST DISTRICT.

The supplement to the *British Burmah Gazette* of the 13th instant contains the report of Mr. R. Frost, the Veterinary Instructor, British Burman, on the outbreak of cattle-disease in the Amherst District. We have gone carefully through this report, which brings to light some plain facts that ought to arouse public attention to a matter of such grave importance. We entirely agree with the conclusions arrived at, and the reasons given by Mr. Frost in respect to the origin and spread of disease among cattle generally. That the water-supply is at the bottom of nearly every outbreak of epidemic among cattle, we have not the slightest doubt. Mr. Frost paints a true picture when he says: "What we generally find in these cases (tanks and *ins*) is that all the cattle of the locality have free access to the water; the buffaloes wallow in it, *cattle and buffaloes dung and urinate in it*. As the weather gets warmer in April, rapid evaporation takes place, and in a short time the animals are compelled to drink a concentrated solution of *feces, urine, and water*. This is not an exaggerated picture. It is a plain statement of facts as they have come under my own observation. When animals have been compelled to drink water of this kind for a short time, disease soon shows itself and spreads with alarming rapidity. Whether this was the case in the Kawkaireik township, where the disease appears to have made its appearance first, I cannot state from my own personal knowledge, but from all I could gather, I am inclined to attribute the outbreak in the first instance, to this cause." [The italics are ours]. What Mr. Frost has brought to light here is perfectly correct. We have ourselves been witnesses of scores of instances in India where a tank or *huul*, common to a village, was polluted by cattle being allowed to wallow, dung and urinate in it, and afterwards drink this *stagnant* water. It is perfectly clear that the villagers are ignorant of the effects produced by allowing cattle to drink this water, and it therefore becomes patent every day that the Government should take imperative measures to remedy this state of things. The only way to bring about an improvement is by instruction. If any further proof were wanted of the need of instruction among the ryots, we have it in the following remarks by Mr. Frost in another part of his report:—

"The effects of the conduct of cattle-owners in connection with this disease (rinderpest) are much to be deplored, and the action of the owners of diseased cattle is such that incalculable injury is done in almost every instance. A plain statement of facts will prove the truth of my remarks. Disease make its appearance in a herd in a village, the owner takes no notice of the sick beast or beasts till an advanced stage of the malady, the sick and healthy are permitted to wander about together for several days, other members of the herd contract the malady, it then spreads to the herds of other cattle-owners of the same or neighbouring villages, for it is a common occurrence for the cattle of several villages to graze on the same *koon*, each fresh herd that becomes affected becomes a fresh centre of disease. The discharges from the bodies of the affected cattle contaminate the pasturage which is enjoyed in common by perhaps hundreds of cattle, and they become infected in time. Animals are permitted to die in the jungle, and their bodies are allowed to rot where they fall, thereby contaminating the air for a considerable distance, and rendering healthy animals that breathe it liable to be attacked. In this disease the sick animals suffer from great thirst, and they generally find their way to the nearest tank, *in*, or creek. It is not an uncommon sight to find sick beasts standing in the tanks or *ins* common to the village herds, the discharges from their bodies mixing with and contaminating the drinking water, which in time produces the disease in those that partake of it. It often happens that the animal dies on the river's bank, the dead body is thrown into the water, and is carried away by the current; it is either carried out to sea, or is left high and dry on the river's bank miles away, where it becomes a fresh centre for the spread of the malady."

This is a horrible picture, but it is true nevertheless, and is as much applicable to India as to Burmah. Mr. Frost remarks that "there is no doubt that this state of things is due in a measure

to the want of knowledge of remedial agents of ordinary cultivator; but it cannot be denied frequently the result of apathy and indifference of catching the sick, and of administering nourishment, is considered too great to exert himself to such an extent." He says that it is the crass ignorance that prevails among owners of cattle generally that leads to such disastrous results. It is for agricultural departments and district and revenue officers to promulgate such practical knowledge among these ignorant people as will open their eyes to the great risks involved in permitting diseased cattle to herd with the healthy. Once they are convinced, that it is to their interests to avoid this, some satisfactory results might be looked for.

Mr. Frost's report is one of the most practical and unvarnished narratives of the kind we have read, and we have reproduced it in *extenso* elsewhere. It is very important, and should be read by every one interested in the welfare of Indian stock.

COTTON CULTIVATION IN UPPER INDIA.

It will interest agriculturists in other parts of India to learn that cotton is raised by irrigation in the N.-W.-P., where it is practically considered to be a wet crop. From experiments carried out at the Cawnpore Agricultural Station during the *kharif* season of 1884, some interesting facts may be gleaned relative to the manuring of cotton-land, sowing seed, cropping, and exotic cottons. In the first place it is necessary to bear in mind that the *kharif* are the rainy-season crops sown in June and July, and harvested in September or October. The manure used was either *cowdung* or *poudrette* at the rate of 200 manna to the acre. *Poudrette* takes the lead in productive output. It is worth knowing that *woollen refuse* from the mills has been tried as a soil improver with satisfactory results. Its price on the spot is 4 annas a cart-load, or Rs. 1-4-0 per 100 manna, which is only half the price of *poudrette* charged by the Cawnpore Municipality. But the Director of Agriculture is of opinion that *cowdung* is perhaps, after all, the cheapest and most profitable fertilizer, as it is certainly the manure most readily procurable by Indian cultivators. From published details of the ploughing done at the Agricultural Station during the past *kharif* season, we learn that the comparative value of ploughing, as done by ordinary country ploughs and with earth-turning ploughs, 5 and 9 inches deep, shows decidedly in favor of the latter, notwithstanding the fact that the ground was twice turned under the first-named implements. The advantage of a thorough inversion of the soil over mere scratching, not only implies a larger outturn for labor worked, but economy in the long run of agricultural operations. It is not a little surprising to learn that the country method of broad cast sowing produced a much larger outturn than ridge-sowing. This is attempted to be explained in the reports by the fact that when sown broad-cast, the plants being much closer when dropped in lines, keep down weeds which have more scope under the latter arrangement, and soon quite overpower the plants. It is interesting to know that sowing in ridges gave a better yield than either on the slopes or in the hollows between them. But these results cannot, from the limited experiment, be considered as final. Cropping the plants for a second year gave inferior results to those obtained from the same field in the succeeding year, and to the cotton gathered from fields sown this year, with similar varieties of cotton. It is therefore a distinct disadvantage to take two crops of cotton from the same plant; and when we consider that the value of cotton seed is so very low, and the labour so very cheap in this country, the advantage of keeping the crop on the ground for a second year, which will only give an outturn equal to one-fifth or one-sixth of that of the preceding year, is practically nil. The ground, moreover, loses considerably by the rest—so to speak. The course suggested by the Assistant Director as best is, that after raising one crop, to plough up the land, and leaving it in open furrows till the next season for sowing. The attempts made to introduce exotic cotton have not met with the success that was anticipated.

FODDER.

In this age of "silos" and "ensilage," too much cannot be said in favor of proposals to encourage the cultivation of fodder crops in the rural economy of India—particularly in those localities where there is but little pasture. Starvation and ill-regulated feeding has more to do with cattle deterioration in this country than climate; and any attempt towards improvement can only prove futile until the people learn to feed their cattle better. There is no question of greater importance, socially and fiscally, from a political standpoint, than the preservation and improvement of indigenous cattle in India—for draught and farm-work. Wholesale reform is necessary to improve the condition more than the breed of cattle nearly all over the country; and this can never be effected until it can be proved to cultivators, that it will pay them equally as well to bestow the same care in the cultivation of fodder-crops, as in that of grain. The superiority of the breed of cattle in the Punjab is ascribed to the fact that the custom is all but universal there to grow certain crops for no other purpose than for feeding cattle. The same plan followed in other provinces could only lead to that improvement which better treatment must bring about, and which is so desirable for the agricultural requirements of an agricultural population. The poverty of the ryot is the great obstructive factor, and has more to do with retarding advancement than ignorance and prejudice combined. He can ill-afford any share of his small plot of ground for "experiment,"—as raising fodder would, at first sight, appear to him as well as others round and about him. The solution of the difficulty resolves itself into one word—"encouragement." He will concede that his cattle need better food and better care; and the incumbent duty of those most concerned—responsible for his well-being, pecuniarily and morally—is obviously "concession" and "instruction." With inducements given and benefits explained him, the cultivator would not be such a fool to his own interests as to neglect the opportunity. The inducement referred to is land free, or at a reduction of rent; and the instruction necessary to enable him to "see and judge" for himself of the advantages to be derived from its cultivation with fodder, could best be imparted through model farms established at centres easy of access in every district or zemindary. He would there learn what fodder would be best to raise for his animals, or even for sale. The best suggestion that comes to us relative to teaching the people that fodder cultivation is profitable, is that for the establishment of fodder farms at all cantonments, for the wants of cavalry and artillery horses—where there would be a constant remunerative demand for a large supply of fodder of the best kind. An authority on this matter says: "Hay and artificially grown fodder in cantonments would be invaluable in supplying the wants of the cavalry, artillery, and slaughter cattle. A farm for such crops would be plentifully supplied with manure by conservancy sweepings, cavalry and artillery horse-litter, and commissariat and slaughter-house refuse." This would prevent the depredations of grass-cutters, who trespass into village lands and carry off fodder that is barely enough for the wants of village cattle. The saving that a fodder-farm would effect by a large reduction in the establishment of grass-cutters would, in itself, be a item well worthy the attention of military economists. Besides, the possibility of having to remove horses into camps many miles from cantonments, in search of grass during periods of drought or scarcity, would be averted. The present utter neglect of the military

THERE has this respect has been justly censured "not only retention open policy," but as "unworthy of a great Military it at present inducement towards the establishment of a cise appm would be, that soldiers might find it worth their were ca work in it; and that it would be a beneficial means the ruling a certain number of them to usefully occupy much Both idle time.

Miscellaneous Items.

THE mango crop at Goa was not so scarce as it was tardy. It is reported that the bazaar at Mapuca abounds with mangoes as big as they are sweet, at a hundred per rupee of the best sort.

IT is notified in the last number of the *North-West Provinces Gazette* that, subject to certain modifications, section 50 to 55A of the *North-West Provinces Rent Act, 1831*, shall be in force in the Family Domains of H. H. the Maharaja of Benares.

A NEW industry has been created at Mahé by an enterprising French gentleman. This consists in the curing and packing of small fish resembling sardines. These fish are despatched to France, and doubtless again find their way out as the genuine article.

WE hear that owing to very heavy rains in the Cuddapah district, the bund of the Cuddapah-Kurnool Canal has given way, and the water from the Canal and from the river Pennar has submerged two villages about twenty miles to the north of Cuddapah.

THE Forest Commission recently appointed by the Bombay Government will be formally opened by H. E. the Governor in the Council Hall at Poona on Thursday next. After the formal opening at Poona the Commission will re-assemble on a date to be fixed hereafter at Thane.

THE details of the reorganisation of the Veterinary Department, in special connection with the proposed Civil Veterinary Department, are now being worked out at Simla by a special committee, consisting of Colonel Hunt, Colonel Low, Colonel Bashman, Major Deane, and Messrs. Hallen and Oliphant.

THE total number of coconut trees licensed for "toddy-drawing" in the town districts of Pondicherry for the year 1885 is 4,232 and of palmyra trees 4,903, producing an aggregate revenue to the State of 26,378.54 francs, or, at 206 per rupee, Rs. 12,804. The tax on each coconut tree is 6.19 francs per year and on palmyra trees from 25 to 75 centimes per year.

THE Pondicherry Government is engaged just now in distributing small sums of money among the poor of the town and suburbs who lost their huts during the late floods. The delay in the distribution of the charity was due to the want of funds, but the late grant of the Home Government of half-a-million of francs has placed the local administration in comparatively easy circumstances for the time being.

THE cultivators, about one thousand in number, who went to Poona to lay before his Excellency the Governor their grievances in connection with the stringent working of the forest laws, have returned to their respective villages. In reply to their petition, they were informed that they will have to appear at the forthcoming sittings of the Forest Commission, by the members of which body their grievances and complaints are about to be examined into.

WE hear that the Madras Tenancy Bill, which was under consideration for several years and unfavourably commented upon by most revenue officers, has been given up, and the subject again referred to a Committee, of which, among others, Messrs. F. Webster, P. Chentel Row, and Hon'ble S. Subramania Iyer are members. We hope that the new Committee will be able to produce a Bill calculated to meet with better reception from the Revenue officers of the Government and from the public in general.

A FEW cases of cow-killing by poison have come to light at Rawal Pindoo. Some strong poison mixed either with little dough or lump of rice was given to a cow, at graze or at the cow-stall, and the consequence was that in about half an hour after the poisoned food had been eaten, the cow died from the effects of the poison. A fit of convulsion at first overtook the victim, and a quantity of bluish foam issued from the mouth before death. The cruel agents of this nefarious practice of killing cows by poison are supposed to be men employed by the contractor who had paid a certain sum of money to Government for permission to utilize the hides of dead kine. A post-mortem examination was held on one of the poisoned cows, and the poison was extracted from the stomach. Some of the culprits are awaiting trial to the Cantonment Magistrate's Court. We postpone our remarks as the case is sub-judice.

WE learn that the Madras and South Indian Railway authorities are having photographs taken of the large bridges and other large works on their respective line to be forwarded to the forthcoming Colonial and London Exhibition. Of those selected on the Madras line are the Central Station, the Bailipally and Tiger Rock cuttings, and the bridges over the Pennar, Palar, Huggery, and Chittravuthy; and those on the South Indian line are the bridges over the Palar, Gingee and Cauvery, and the Workshops at Negapatam.

THE first sitting of the Abkari Commission held lately at the Secretariat, under the presidency of Mr. J. H. Grant, Collector of Bombay. Euljee Dossabhoj, one of the representatives of the Hoensed country liquor sellers of this city, who gave his evidence before the Commission, said that the system of selling licenses by public auction was attended with great evils. It introduced an element of harassing uncertainty in the trade, and took away largely from the incentive to fair dealing and respectability, which could only be afforded by a sense of security and stability in their business. He maintained that the public sales bore heavily on the liquor-sellers, and that although there was at present an increase in the Government revenue, a reaction must set in, and in the long run the Government themselves would suffer. He suggested that the auction system should be abolished, and the license fee should be fixed on a fair and reasonable basis. There was a large attendance of liquor-sellers, who watched the proceedings with great interest.

Selections.

CATTLE-DISEASE IN THE AMHERST DISTRICT.

THE subjoined report of Mr. R. F. Frost, Veterinary Surgeon, concerning cattle-disease in the Amherst district, is published for general information. The attention of District Officers in other parts of the province is invited to the need for improving the water-supply of cattle, for insisting on the burial of bodies of diseased cattle, for restricting, as far as may be, the movement of cattle within and from tracts affected by rinderpest. The Chief Commissioner has recently advised the Government of India that a Cattle-Disease Act, somewhat on the model of the recent Madras Act, is required for Burmah. The Act would be extended to any part of the province on cattle-plague appearing, and could be withdrawn from such tract as soon as the scourge abated.

From R. F. FROST, Esq., A. V. D., Veterinary Instructor, British Burmah, to the Deputy Commissioner, Amherst.—No. 3589, dated the 3rd August 1885.

I HAVE the honour to report for your information the result of my inquiries into the recent outbreak of disease among the cattle of your district, and to acquaint you with the result of my inspection of the Veterinary Assistants employed under you.

II.—*Nature of the disease.*—The disease from which the cattle have died was true rinderpest, a disease which is highly contagious and infectious, and which plays sad havoc among the herds of this province almost every year. The terms used by Burman cattle-owners to indicate disease are "blood-purging" and "smallpox." When severe enteric symptoms show themselves, they use the term "blood-purging," and when an eruption appears on certain parts of the skin of the body accompanied by mild derangement of the bowels, the term "smallpox" is applied to the malady. Of these two forms of the disease the latter is the least fatal. Many recoveries take place when a copious eruption takes place, while only a very small percentage recover when the enteric symptoms are well marked. It is very rare that the eruptive form is met with among buffaloes, and even in cattle, only a very small proportion of those attacked show this peculiarity of the disease.

III.—*Cause of the outbreak.*—I have been unable to glean any facts that would justify a positive assertion as to the origin of this recent outbreak. Such a long time had elapsed between the first appearance of the disease and my arrival at the scene of the outbreak, the difficulty in obtaining any reliable evidence as regards facts or dates from cattle-owners, facts that would aid me in tracing the disease step by step to its origin, and the utter indifference of the people to the matter of the loss of their cattle, have rendered it impossible for me to state where the disease originated, much less to offer an opinion as to its cause. That the disease spread rapidly owing to its contagious and infectious character there can be no doubt, but there was not

the most remote chance of being able to obtain a clue as to where the disease first showed itself.

But although I am unable to enlighten you as to whether the disease on this occasion arose spontaneously and had its origin within your own district, or was introduced by foreign cattle, I may be permitted to add that I am strongly of the opinion that there are sufficient causes in operation as affecting the health of the cattle of your district, as well as almost every district in the province to give rise to this dreadful disease. If the disease may have been introduced by drovers' cattle entering the district via Myawadi is, of course, quite possible, but there is nothing to be gained by speculating on this part of the question now; there is no reliable evidence available to prove that it was introduced by them.

The conditions necessary for the maintenance of the health of cattle are very intimately connected with their food, their drinking-water, and the shelter supplied to them.

If any of these three conditions are wanting, the health of the cattle must suffer more or less. Shelter may be dispensed with without any serious injury, a scarcity of fodder may be experienced without any more serious consequences than a loss of flesh and an increased predisposition on the part of the animal to attacks of disease, but an impure or an insufficient water-supply is generally followed by the most fatal consequences.

It is a well-established fact that when animals are compelled to drink bad or impure water, they are rendered especially liable to disease of a putrid and of an enteric character. Bearing this in mind, I shall now ask you to recall to your memory the sources of the water-supply of the cattle of those parts of the province where you have served. Take Hanthawaddy, Pegu, Thongwa, Bassein, Tharrawaddy, Prome, Akyah, and Henzada districts as examples of what I wish to impress upon you. I select these districts because I desire to allude to such places only where I have had an opportunity of studying the water-supply for cattle during these months, when it is so absolutely necessary and when it is so very scarce, and that from March to the commencement of the rains. I find that cattle herded in the vicinity of large rivers and streams where the water is sweet are favourably situated, but my remarks do not point to these cases. I allude to those localities where the cattle have, owing to the presence of brackish water, to depend upon tanks and ins for the water which they drink.

What we generally find in these cases is that all the cattle of the locality have free access to the water, the buffaloes wallow in it, cattle and buffaloes dung and urinate in it. As the weather gets warmer in April, rapid evaporation takes place, and in a short time the animals are compelled to drink a concentrated solution of feces, urine and water. This is not an exaggerated picture. It is a plain statement of facts as they have come under my own observation.

When animals have been compelled to drink water of this kind for a short time, disease soon shows itself and spreads with alarming rapidity.

Whether this was the case in the Kawkaeik township, where the disease appears to have made its appearance at first, I cannot state from my own personal knowledge, but from all I could gather, I am inclined to attribute the outbreak, in the first instance, to this cause.

The Sanpannago circle of the Martaban township is one of the great grazing-grounds for that part of the country, and, in reply to inquiries of mine, Mr. Hough informed me that the description which I have given above of the drinking-water generally available for cattle describes the character of the water which is available for the herds collected in many parts of his subdivision and of the cattle in Sanpannago circle in particular.

I have only to add that a very serious outbreak of rinderpest occurred in the month of April among the herds collected in the Sanpannago circle.

The prevailing opinion with regard to this disease is that it is due to the consumption of large quantities of fresh, luxuriant, green grass, which springs up so luxuriantly at the commencement of the annual rains. Such a theory cannot be supported in connection with the recent outbreak in your district for the reason that the disease had made its appearance, and had swept away thousands of animals before the rains set in.

I could point to several other instances where outbreaks have had no connection whatsoever with the advent of the monsoon or the consumption of green grass.

IV.—Area involved in the outbreak.—The disease has extended over a very considerable part of the district. The whole of the

Kawkaeik township has been involved, and the loss has been remarkably high in this township.

The south-eastern part of the Hlaingbwe township, where there were a good deal, especially the Dawlan circle, where, I was able to either visit or send my assistants, every village suffered more or less.

Gyasing-Salween as well as Gyasing-Ataran townships have been visited by cattle, but not to the same extent. It is highly probable that the real facts of this outbreak could be ascertained, and if complete rate figures were forthcoming, we would learn that the disease had spread over a much larger area, and that a much larger number of deaths had taken place.

V.—Treatment of sick animals.—It may be said that no efforts are made by the cattle-owners to save the lives of their sick beasts, several days are allowed to elapse before any attention is paid to the sick animal. It is not till the disease has been fully developed, till purging has set in, and there is a complete disinclination to eat, or until the animal becomes so weak that he cannot stand, that the attention of the owner is aroused; even then little or nothing is done beyond bringing the patient in from the kwin, tying him under the owner's house, where the poor beast has often to stand in filth fetlock deep, and being then subjected to a most barbarous method of treatment, having a mixture of salt and chillies, or salt and onions, placed in the mouth, nostrils, and eyes. No endeavour is made to support the strength of the animal. A little grass, which the beast will not touch, is placed before him, and nature is allowed to do the remainder, which it generally does by putting an end to the poor beast's suffering.

There is no doubt that this state of things is due in a measure to the want of knowledge of remedial agents on the part of the ordinary cultivator; but it cannot be denied that it is more frequently the result of apathy and indifference. The trouble of catching the sick, and of administering medicines and nourishment, is considered too great to induce the owner to exert himself to such an extent.

VI.—Preventive measures resorted to by owners.—The effects of the conduct of cattle-owners in connection with this disease are much to be deplored, and the action of the owners of diseased cattle is such that incalculable injury is done in almost every instance.

A plain statement of facts will prove the truth of my remarks. Disease makes its appearance in a herd in a village, the owner takes no notice of the sick beast or beasts till an advanced stage of the malady, the sick and healthy are permitted to wander about together for several days, other members of the herd contract the malady, it then spreads to the herds of other cattle-owners of the same or neighbouring villages, for, as you know, it is a common occurrence for the cattle of several villages to graze on the same kwin. Each fresh herd that becomes affected becomes a fresh centre of the disease. The discharges from the bodies of the affected cattle contaminate the pasturage which is enjoyed in common by perhaps hundreds of cattle, and they become infected in time. Animals are permitted to die in the jungle, and their bodies are allowed to rot where they fall, thereby contaminating the air for a considerable distance and rendering healthy animals that breathe it liable to be attacked.

In this disease, the sick animals suffer from great thirst, and they generally find their way to the nearest tank, in, or creek. It is not an uncommon sight to find sick beasts standing in the tanks or in common to the village herds, the discharges from their bodies mixing with and contaminating the drinking-water, which in time produces the disease in those that partake of it.

If it so happens, as it often does, that the animal dies on the river bank, the dead body is thrown into the water and is carried away by the current; it is either swept out to sea, or it is left high and dry on the river's bank miles away, where it becomes a fresh centre for the spread of the malady. These dead bodies, in being carried about by currents, frequently come in contact with herds of buffaloes drinking at the river's side, and I need not add that the water contaminated by these dead bodies, if partaken of by healthy animals, is very likely to convey the disease to them.

In my recent journeys through your district this matter was forcibly impressed upon me, particularly on my way up the Gyasing river, where, in a distance of about 10 miles, I counted 33 dead bodies of animals either floating down with the stream or embedded in weeds as bait for fish.

Matters must have been even worse prior to my visit, for I was told by villagers up the Hlaingtharaw that, owing to the number

at were floating up and down that river with the had to discontinue the use of river water for some time.

THERE has been retention of the ill-effects of allowing the dead bodies to rot in it at present thereby contaminate the atmosphere, there is an- cise app. all more forcible, objection to this method of disposing were ca. Birds of prey and dogs that have feasted on the the run. a well-established fact, become powerful agents in Both the contagion of the disease to considerable distances. all people were to combine with the object of spreading the noise as much as possible, they could hardly be more successful their efforts than they have been. Not alone is nothing done to check the disease, but everything is done to facilitate its extension. Sick cattle are turned loose to mix with the village herds, the drinking-water is contaminated by them, the pasturage made a fruitful medium for conveying the disease, cattle are moved from infected to healthy localities regardless of the fact that disease prevailed amongst them. Indeed, worse than this, I have been informed by men that they have bought cattle from diseased herds for low prices, and removed them to other localities in hopes that they may escape infection, or if not that, the loss of even half the animals' purchase would leave the price of the remainder still below their market value. A remarkable example of this came under my notice at the village of Khaya. A cultivator purchased two buffaloes at the village of Pata, in the Dawlan circle, in the month of April. He was well aware of the fact that rinderpest prevailed among the herds at Pata at the time, but the low price (Rs. 30) at which the pair of buffaloes was offered to him proved too great a temptation, and he became their owner. In a week after his return to his own village (Khaya) one died, and in a few days the second was carried off. Previous to this not a trace of the disease was noticed among the herds in Khaya, but soon the disease spread from herd to herd until, at the time of my visit, not a herd in the villages of outer and inner Khaya had escaped. I have not the slightest hesitation in stating that a large trade in diseased, or perhaps what I ought to term suspicious, animals, is done during the prevalence of an epidemic of rinderpest, that this trade helps in a great measure to spread the disease, and that incalculable loss is caused thereby.

The flesh of animals that have died from rinderpest is exposed for sale, or it is cut up in strips and hung up to dry, sometimes close to where the healthy cattle are tied, and it is a common sight to behold the hides taken from the dead bodies piled up in close proximity to the living animals.

The unrestricted movements of cattle through the country during the prevalence of an outbreak must always prove a most important factor in spreading the disease. Some facts, which came to my knowledge while travelling in the Martaban township, will verify this statement. Large numbers of cattle used in cultivation on the Martaban plain are put out to graze annually in the Saupanago circle. They are brought back each year immediately before the commencement of the ploughing season. This year disease made its appearance among the herds in the Saupanago circle some time in April or early in May. In a short time the cultivators removed their herds amongst which the disease had established itself, and in a short time almost every village from Martaban to Yinuyaing was a centre of the disease.

Although I have been unable to gather any trustworthy information on the point, I have little doubt in my own mind that drovers' cattle passing through the Kawkaireik township during the prevalence of the outbreak did considerable mischief in aiding the spread of the disease. Large droves of oxen and buffaloes pass through Kawkaireik every year. They halt for some time at Kawkaireik, where large numbers are disposed of, and then move westwards towards Thabon, Kyaukse, Pegu, Hanthawaddy, and Thongwa, and other places. This year large herds were at Kawkaireik during the prevalence of the disease, and it is only reasonable to suppose that they did not escape infection. Indeed I have been frequently told that these herds suffered severely both during their sojourn at Kawkaireik and on the march through the township. That disease prevailed in these herds may be inferred from the circumstance that the drovers were willing to dispose of their animals at prices much below the usual market rates. These herds, in their progress through the province, mix freely with the cattle of the different villages, they frequent the large grazing grounds, and halt for days where grazing and water are abundant. If disease prevails among these herds, it is not difficult to understand the vast amount of harm that they are capable of doing; not alone are herds on route infected, but animals purchased from the drovers and

taken to villages at considerable distances, as is the case, convey the disease to their new homes, where it spreads with fatal rapidity.

I have here stated facts as they have actually taken place, and I think my assertion, that nothing is done to check the disease but everything is done to facilitate its extension, is fully borne out by these facts.

VII.—Indifference of Township Officers in the matter.—As a rule the Township Officers paid little or no attention to the recent outbreak. The Hlaingbwe Myook paid a hurried visit to the village of Dawlan when the disease had been raging for some months. He issued an order to the Dawlan talk-thugyi in the month of May to the effect that the bodies of all cattle that died were to be buried immediately, and that any person disobeying this order would be dealt with under section 184 of the Indian Penal Code. Putting aside altogether the legality of the order, which I believe is open to considerable doubt, I may state that no action was taken to ensure the observance of the order.

The Township Officer of Gyang-Salween seemed to take no interest whatsoever in the matter. He was aware of the fact that disease prevailed at the village of Khaya, but he had not been to the scene of the outbreak. He informed me that there had not been any sickness in his township during the year with the exception of this outbreak at Khaya. He was quite ignorant of the fact that disease prevailed among the herds at Sante and Kawiama. It appears that there was a serious mortality among the cattle in Zathabyin village about February and March, yet the Myook seemed to know nothing about it.

The Township Officer of Kawkaireik has taken no active measures to obtain statistics of the number of deaths which have taken place. This officer has directed that talk-thugyis are to submit weekly reports of the number of deaths of cattle, yet in the face of this order he accepts monthly reports instead. At the time of my visit to Kawkaireik I learned from the Myook that a large number of deaths had taken place in the Myewadi circle, and on asking for the returns I was informed that none had been received.

The same indifference prevailed in the Gyang-Salween township. Deaths were reported from Pabyank, Payogyi, and Myawadag, but a large number of animals died in the Migalon circle about which the Township Officer knew absolutely nothing. The impression left on my mind after conversing with the Township Officers on this subject was that it was one which gave them very little concern. They one and all tried to shift the blame, whenever blame was due, on to the shoulders of the talk-thugyis, and they seemed to think that all they had to do was to forward such reports as they may receive from the talk-thugyis to the district office.

VIII.—System of reporting outbreak by talk-thugyis.—I cannot write too strongly of the manner in which the present system is worked. During the whole time that I have been engaged inquiring into this recent outbreak, I have not found a single instance of a reliable report having been made by a talk-thugyi. These men, as a rule, took no action in the matter till the disease had obtained firm hold of the herds in their circles. In some instances they were in perfect ignorance of the prevalence of the disease.

I shall quote a few examples. The Dawlan talk-thugyi admitted to me that disease prevailed in about 11 villages in his circle, and that at least 1,000 animals had died from March up to the end of June. He reported 220 deaths as having occurred in the villages of Dawlan and Kyoikpaw, which almost adjoin Dawlan. He informed me that he had made no efforts to ascertain the number of deaths in the other villages of his circle.

The thugyi of the Myapadaing circle, although he resides at Kyundo, knew nothing about the prevalence of disease in the village where he resides. A large number of cattle died in Kyundo, one Karen having lost about 50, yet the talk-thugyi never reported deaths from Kyundo nor did he know that disease prevailed at the time of my visit.

The villages of Thayettaw, Kanni, and Kyalog in the Migalon circle suffered a good deal, yet the talk-thugyi knew absolutely nothing about the mortality until I enquired about the facts.

On comparing last year's return of the number of buffaloes and cattle in the circle with the return for the present year, I found that there were 482 buffaloes, cows and bullocks less in the circle this year than there were last year. The talk-thugyi explained this difference by stating that this year many natives of India came up to Migalon to purchase cattle, and that they took them away to Moumeia. I am inclined to think that he would have found a more correct explanation of this falling off of over 35 per cent. of the cattle in his circle, if he had made himself

acquainted with the number of deaths that took place during the months of March, April, and May.

I might quote several cases of a similar kind, but I shall confine myself to one other, that of the Mukyit talk-thugyi. An owner of a sick buffalo was told that, if she reported the matter to the Mukyit talk-thugyi, veterinary medical aid would be supplied by Government. The woman sent her son to Kwechan village to inform the talk-thugyi that her buffalo was ill and to ask for assistance. On reporting the circumstance the boy was told by the talk-thugyi to report the matter to the kyedangyi, and that was all the veterinary medical aid the woman received for her cattle.

Subsequent to this I visited Kwechan, where I found cases of rinderpest, but the thugyi knew nothing about the matter. He was ignorant of the fact that the disease prevailed in his own village, and he told me that all he had to do in the matter was to make an abstract of the kyedangyi's returns and submit it for the information of the township officer.

In those cases where the talk-thugyis have failed to make themselves acquainted with the state of the health of the cattle in villages in their circles, and where I found that disease had prevailed but deaths had not been reported, the thugyis invariably put the blame on the kyedangyis, who, they say, cannot be got to report deaths. I have inquired into many of these, and I have found almost in every case that the kyedangyis have never been ordered to report the deaths of cattle. They say it is their duty to collect statistics relating to deaths among the people, but that they have nothing to do with furnishing information regarding the death of cattle.

The kyedangyi of Kanni went so far as to say that he mentioned, in a casual kind of way, to the Migalon talk-thugyi that cattle were dying in his village, but that the talk-thugyi did not direct him to collect any statistics as to the number of deaths.

IX.—Value of statistics.—Much doubt has been expressed by officers as to the utility of collecting even approximately accurate figures of the number of animals that have died during the recent outbreak. In my mind it is a matter of vital importance, and

if we could collect reliable information regarding the number of deaths that have actually taken place, we would find that a very serious loss has been sustained by cattle owners generally. Taking a broader view of the matter, I am convinced that thousands of cattle die annually in British Burma from preventable disease, and that owing to the generally defective system of reporting deaths, District Officers must remain in ignorance of the magnitude of the annual loss suffered by cultivators.

From the facts which have come under my personal observation, I am deeply impressed with the great necessity that exists for the introduction of legislative measures, with the view of checking the spread of this dreadful plague among the herds of the province, but until I can prove by figures that a necessity exists for the introduction of legislative measures, my recommendation and my warnings must possess but little force. But were reliable figures forthcoming, I am sanguine that I would be borne out in my views, and that then the Government would be made acquainted with a state of affairs of which it can form no adequate idea at present.

The following figures will give some idea of the high rate of mortality. The figures show the number of animals in 12 villages of the Myapadaing circle of the Kawkaireik township, and the number of deaths reported from each village during the months of May and June of the present year:—

No.	Number of buffaloes in village.	Number of bullocks, cows, and oxen in village.	Number of buffaloes died.	Number of bullocks, cows, and oxen died.	Buffaloes, Percent- age of deaths.	Bullocks, cows, and oxen, Percentage of deaths.
1	277	80	112	34	40.43	42.50
2	75	78	45	44	60.00	57.58
3	123	87	101	36	82.93	41.38
4	397	43	106	83	31.45	88.34
5	178	..	94	14	18.54	..
6	25	273	..	245	..	88.98
7	264	116	195	95	49.40	81.93
8	606	2	176	..	29.04	..
9	329	..	57	2	17.31	..
10	218	..	190	13	37.15	..
11	208	75	202	60	68.24	80.00
12	322	..	120	7	37.26	..
Total	3,840	692	1,898	640	39.15	71.74

These figures must be considered as only approximate. The figures in the second and third columns have been taken from the return of the number of animals collected last year by the talk-

thugyi. In some villages you will observe that there were no cows, bullocks, or oxen, yet deaths of cows, bullocks, and oxen were reported during the recent outbreak. This may be due to either of two causes: one, that cattle may have been purchased by cultivators subsequent to the collection of these statistics in June or July last year; the other, and the most likely explanation, is that the annual return of animals as submitted by the talk-thugyi was not correct. I think I am right in stating that talk-thugyis take little or no trouble in collecting these statistics. They compile their returns upon the information which they collect from a few men from each village, or the kyedangyi is deputed to collect the figures. I shall give you a case in point. According to last year's return there were 25 buffaloes, two cows, and one ox in the village of Kyaing in the Migalon circle; according to the return for the present year there are neither buffaloes, cows, nor oxen in the village, yet I found 20 head of cattle there when I visited the village, and these animals had been in the village for years.

But although the figures may not be accurate, I think they are strong evidence of the fact that a very heavy burden has fallen on the people, and I am quite certain that other circles have suffered equally, but there are no figures available to show to what extent they suffered. For example, in the month of May, 1,014 buffaloes, cows, and oxen were reported as having died in the Kawkaireik circle during the month of April. Again, in the next 15 days of May, 2,310 animals were said to have died in 12 villages of the same circle. After this no deaths were reported. This shows that 3,754 animals died in the Kawkaireik circle alone. I may here add that I was informed by the kyedangyi of the natives of India residing in Kawkaireik that he had not, previous to my visit, reported any deaths from among the cattle of natives of India. He furnished me with a return which showed that 27 natives of India had lost, during the recent outbreak, 325 cows, bullocks, and oxen and 33 buffaloes. This shows that 4,122 animals died in the Kawkaireik circle alone; and if we add the number of deaths reported from the Myapadaing circle (2,038), we have a total of 6,160 deaths in these two circles. I am unable to state how many deaths have taken place in the other circles of the township, but I was informed by the township officer that disease prevailed in the other circles of his township, but that he had not received any reports from the talk-thugyis.

I would wish to allude here to some figures which I was enabled to obtain of cattle deaths in the Hialingbwa township during the prevalence of some previous outbreaks.

In the year 1882 I find that in six circles of the Hialingbwa township 2,154 animals were reported to have died between the 15th May and the 1st September.

In the year 1883 the records show that 6,415 animals died between the 15th March and 15th September.

Certain quarterly records for 1883 show that 5,161 animals died during the prevalence of a severe outbreak of rinderpest in this year.

There are no records for the year 1884. Taking the lowest figures, we find that in this one township alone over 2,000 animals were swept away in two years, 1882-83. This represents a money loss of about Rs. 2,00,000 to the cultivators of the township, and the money loss caused by the recent outbreak in the two circles of the Kawkaireik township may be said to amount to about Rs. 1,50,000.

In the absence of reliable statistics you will understand how difficult it is to even hazard a statement as to the value of the cattle that died during the present year. We know that the disease prevailed in six townships of the district, and, if we bear in mind the highly contagious and infectious nature of the malady and the facilities afforded by cattle owners for its spread, we may feel confident that the money loss has been enormous.

My object in alluding at such length to this part of the subject is to show that if reliable information could be obtained as to the number of deaths that take place on occasions of epidemics, strong grounds would be established for asking for some legislative measures to deal with outbreaks.

X.—Veterinary Assistants and the outbreak.—I am very sorry to be obliged to add that these young men have been of little or no use in connection with the recent epidemic.

The Veterinary Assistant Maung Po Khin, employed under the Assistant Commissioner, Thaton, fell sick just at the time when his services were most needed, and when Mr. Maugh ordered him to go to the scene of an outbreak in the Thaton subdivision. Notwithstanding that the Medical Officer certified that the man was fit for duty he flatly refused to obey Mr. Maugh's orders, on the plea that his constitution would suffer if he exposed himself to the vicissitudes of the season. This man has been suspended, and he will not be further employed in your district.

The conduct of Maung Shwe Dwa, employed under the Township Officer, Kawkaireik, has been most discouraging. This assistant, notwithstanding that disease has been raging all round him for months, has done absolutely nothing. For months he has been sitting in his house at Kawkaireik, and this too with the knowledge of the Township Officer. On asking the Myook why he did not order the Veterinary Assistant to go about and endeavour to induce the people to adopt some measures of precaution against the disease, he informed me that he had not seen the boy for two months, that he believed he was all the time in his house in Kawkaireik, that if he had sent him out the people would not follow his advice, that the cattle were all wild and could not be taught for the purpose of giving them medicine, and that the people would only laugh at any advice which the Veterinary Assistant may offer with regard to the adoption of preventive measures.

I think the Township Officer might have seen that the Veterinary Assistant did not idle away his time in the manner I have stated. Had he taken an interest in the boy's work, some useful information might have been obtained regarding the extent and

mortality of the disease. Besides, it is on occasions of epidemics like this, to which I allude, that these Veterinary Assistants have it in their power to bring themselves to the favourable notice of cattle owners, not so much in the treatment of sick beasts, as in the prevention of disease. But if Township Officers allow these young men to be to a certain extent their own masters, I see very little chance of getting them to do any useful work.

The Veterinary Assistant Maung Tha Dan Zin, employed under the Medical Officer of Hlaingbwe, endeavoured to do his best in connection with the outbreak at Dawlan, but he could do little owing to the difficulty of inducing the people to follow his advice. Although this boy was supported by all the influence which the Township Officer possessed, and although the Township Officer accompanied him to the scene of the outbreak, still he was able to do little or no good. The people would not go to the trouble of catching the sick cattle for the purpose of giving them medicine, they would not segregate the sick from the healthy, they would not bury the dead, or prevent the healthy animals from coming in contact with the dead bodies. In a word, the boy could not induce the people to follow his advice in even the most simple matter, and the result was the youth became quite disheartened and ceased to advise the people.

The other Veterinary Assistant, Maung Tan Baw, has not been spending his time very satisfactorily. It is true he did not hear of the existence of disease in Balagyun and Gyalang-Ataran till the disease had been for some considerable time in existence, and he could then do very little good. This young man did not impress me very favourably. He is a smart, intelligent youth, but he is very lazy, and he appears to think more of making travelling allowance than he does of his duties.

These Veterinary Assistants require to be more strictly watched by Township Officers under whom they are placed. Township Officers should, I think, be held responsible that these young men move about among the people, and that they bring themselves to the notice of cattle-owners. They should not be permitted to sit in their houses while cattle are dying in hundreds all round them, and the Township Officers ought to endeavour to induce the people to adopt such measures as these young men recommend in connection with the treatment and the prevention of disease.

I am fully alive to the difficulties under which these Veterinary Assistants labour, and I can well understand how discouraging it must be to them to find their efforts to induce the people to adopt rational measures for the protection of their cattle unavailing. Indeed, I am firmly convinced, and so must every one who cares to study the question, that little good can be done by these cattle doctors until some legislative measures are introduced to deal with this question of cattle-disease, a question which is so intimately connected with the prosperity of the province.

JARUL TIMBER.

(Indian Forester.)

The June number of the *Indian Forester* contains a report on experiments made on the Northern Bengal State Railway with sleepers made from certain Assam timbers,—among them Jarul, *Lagerstrœmia Flos Regine*, from which it appears that, after 5 years using in an unballasted siding where of course white-ants and damp would get fair play, out of 100 Jarul sleepers, 48 were found to be in good and 11 in fair condition. And in the first article in the same number of the *Indian Forester*, it is noted that attempts are being made to grow Jarul in Assam. Having had some experience at Akyab of the timber called Jarul by the Bengalees there, and *Pyumna* (not, I think, *Pyumna* as Gamble has it) by the Burmese, I am puzzled how to reconcile that with the account given by Gamble of its qualities, and with what is now reported of the experimental Jarul sleepers.

When I took over charge of the Arakan (F. W. D.) Division in 1867, a large jetty was being finished, of which the piles were all either ironwood, *Xylocarpus dolabriformis*, *Pyinkado* Burmese, or so-called Jarul. The piles were whole trees, unsquared, and the largest were over 50 feet in length and up to nearly 3 feet in diameter at the butt. The Jarul piles were all brought from up the Koladyne River, and they were I think of two kinds, known as red and white Jarul.

The white Jarul was, I believe, the same wood that was used extensively in Akyab for beams and planks in house-building, as being much cheaper than ironwood or teak, but it was notoriously a favorite food of white-ants. It had a grain like ash, and was of about the same color. Gamble says that Jarul (*L. Regine*) is the most valuable timber of Syihet, Cachar and Chittagong, and in Burmah the most valuable after teak, but he describes the wood as being light red. Not having had anything to do with the procuring of the piles for the jetty, I cannot say positively that either the white or the red wood, called Jarul at Akyab, was the produce of *Lagerstrœmia Flos Regine*, but I think there were specimens of that tree at Akyab, and that I was told it was Jarul. And I have seen the *Lagerstrœmia* in Pegu, and heard it called Jarul and *Pyumna*. At this distance of time, having left Burmah in 1870, I cannot recollect having seen the red Jarul in general use, except for the paddles of canoes, for which it was admirably adapted. The color and grain were like a darkish mahogany.

While at Akyab I had to substitute ironwood for white Jarul beams in the roof and floor of the Treasury. The earth all with which the beams had originally been smeared had lost its virtue, and the white-ants had got in. After an interval of leave and

other duty I again received charge of the Arakan Division towards the end of 1869, and was surprised to find the T-head of the jetty already extensively in need of repair. The Jarul piles, braces and wallings were rotting, and the pile heads were being eaten up by white-ants, though they stood fully 500 feet from the shore at high water! The decay extended to low-water mark, but below that the Jarul timber seemed to be quite sound. The destruction by white-ants stopped at high-water mark. It had before become known during the construction of the jetty that whereas the *Teredo navalis* freely fed on, or bored through, ironwood, it rejected Jarul as being unpalatable or unwholesome; and then, if I recollect rightly, the natives said they knew Jarul did not stand exposure to the weather, or being alternately wet and dry, as were the piles and timbers down to low-water mark. The timber of the jetty of both sorts had been carefully sheathed with tarred felt and Muntz metal, as protection from the *Teredo*, but in the case of the Jarul this proved the means by which the white-ants were enabled to effect the destruction of the pile-heads. At that distance from the shore it was of course a puzzle—first, whence came the white-ants; and second, whence they got the earth with which they make the galleries without which they cannot, or do not like to work. There is no doubt that the white-ants came from Calcutta or Chittagong, and were landed from the mail steamers, for the use of which chiefly the jetty was built. The cargo was stored in a closed shed by the T-head of the jetty until sent for by the consignees. Even ships themselves are sometimes damaged by white-ants. In 1865, I think, the Lighthouse Schooner *Alquada* was found to be nearly eaten up by them, but where the earthy medium came from in that case, I did not hear. Perhaps those interesting little creatures were then made innocent scapegoats, as in the celebrated case in which rupees were said to have been eaten by them. But in the case of the Jarul piles there was no mistake, and I got literally to the bottom of it. When making a survey of the dockage done, I stripped off the felt and metal sheathing, and found that the ants had worked their way down inside or through the felt to considerably below high-water mark. This of course they did while the tide was low, and there they found the earth they were in quest of, in the shape of silt, deposited from the muddy water of the Koladyne estuary! I saw them going down and up, and they were not there eating the timber. The galleries the ants had made through and through the pile heads above high-water mark were as usual lined or filled with earth. I estimated for cutting off all the Jarul piles down to low-water mark, and putting ironwood heads (ironwood, or *pyinkado*, white-ants and weather) on them, but the Arakan Division was then disbanded, and I was transferred to Bengal before this was sanctioned, and do not know what ultimately was done. I believe, however, that the timber jetty continued to go to grief, and that it has been replaced or superseded by an iron one. I cannot recollect whether I found any red Jarul on the pier-head thus rotten or ant-eaten, but I am under the belief that both red and white timber was used in the work.

What then was this white Jarul, that withstood the *Teredo* but was so easy a victim to the termite, and that was durable (for some years at least) under salt water, but unable to resist the weather? Was it a *Lagerstrœmia* at all? Gamble does not say whether the *Lagerstrœmia Regine*, which has a red wood, resists white-ants. I hope that some fellow-subscriber, if not the Editor, will be able to clear up this point for me, and to give some further particulars as to the merits and demerits of the red and white Jaruls.

Mussorie, June 18, 1885.

C. W. HOPE.

ON THE NECESSITY OF IMPROVED TILLAGE IN BENGAL.

Any one who has paid the slightest attention to the history of Bengal during the last century, cannot but have been struck with the extremely rapid succession of famines during the last twenty years. The following table, taken from the Famine Commission Report, 1878, shows that while from 1762 to 1865, a period of nearly 100 years, the number of famines was only two, that from 1865 to 1885, a period of only twenty years, there were no less than four:—

A TABLE OF FAMINES IN BENGAL.

	Scarcity.	Duration.	Intensity.
1769-70	...	1	...
1763-64	...	1	18
1865-66	...	2	21
1873-74	...	1	4
1877-78	4
1884-85	6

N. B.—One asterisk = Severe scarcity.

Two asterisks = A famine.

Three asterisks = An intense famine.

The asterisks against the year 1877-78 and the addition to the table of 1884-85 are ours.

The natural inference, therefore, is that during the latter period of time, there has come some change in Bengal either over its method of cultivation, its trade or its climate, which renders a famine, or, at all events, a scarcity, almost inevitable during a period of 8-10 years. The activity which the Government of Bengal has lately been showing in agricultural matters is by some interpreted as the result of strong recommendations of the Famine Commission for agricultural improvements in this country, based, chiefly, they seemed to think, on the ground that it is to agricultural improvements alone that we should look for help against the periodical visits of famine. The establishment of an Agricultural Department and the employment under it of specially trained officials, with the object of introducing scientific reforms are viewed by many people with a sort of nervous fear lest the agriculture of this country should be allowed to deteriorate too much to admit of any profitable improvement at a moderate cost; by others again, with genuine fear, but on a different ground, namely, lest the Government, by introducing unknown and unheard of reforms, should ruin the agricultural prosperity of this country. We need scarcely say that we share none of these feelings. We rejoice to think that the Government has at last thought fit to act upon the recommendations of the Famine Commission. We further rejoice that, almost simultaneously with the department, a very well-managed monthly journal devoted to agricultural subjects chiefly, has been started with the laudable object of interesting the educated public in agricultural matters, and we earnestly hope that both the department and the journal may prove a success. As yet, however, we do not think that the public at large are prepared to appreciate and profit by an exposition of the truths of scientific agriculture which have lain up to this date a sealed letter to us. A few words then on agricultural matters in these columns will not, we hope, be without some service to the public.

Notwithstanding the frequency of the famine, the periodical visits of cholera, malarial fever, and other diseases, the check given to early marriage by the gradual spread of education, and lastly, the gradual increase in emigration, the total population of Bengal is on the whole increasing. From the Census Report of 1881 we find that the total increase, all over Bengal, including the Pundatory States during the ten years from 1871 to 1881, was 6,831,143, i. e., about 10.59 per cent. Considering that the year 1876-77 was one of severe mortality owing to famine, we have no reason to suppose that the population has not since increased at more than a proportionate rate. Of this total increase, a considerably greater advance is seen on the urban than on the rural population. Setting aside the insignificant ratio of the boat population, the percentage of the urban on the rural population was in 1871, 20, while in 1881 it was 29, thus showing an increase of urban population of about 30 per cent. Assuming the agricultural population to be, as the Famine Commission Report tells us, about 80 per cent of the total rural population, and that this ratio holds good even at the present day (which however is not the case—the percentage of the urban population is every day increasing) this number, though insignificant in itself, implies that nearly 18,000 people who were presumably born to the agricultural profession had to give it up for some reason or other. It requires little argument to show that a more than proportionate number of the rural population have done similarly since 1881. For, as we take it, the laws that brought about this diminution of the rural population have operated during the last few years, and will continue to operate over afterwards with much greater intensity than they had hitherto done. It is inevitable, as civilization progresses in this country, that this diminution should continually be on the increase. Civilization has for its object the division of labor and the directing of it into different channels, and to this end establishes forms of industry other than agricultural industry. The gradual development of the innumerable and ever-increasing branches of arts and commerce, which absorb a greater and greater portion of the labour which was formerly employed chiefly on agricultural operations, is a necessary condition for the progress of civilization. Taking two of the most civilized countries of the world, we find that the urban population is in neither case lower than 30 per cent:—

India	4.96	Percentage of urban
France	31.06	on total popula-
England	61.8	tion in 1871.

If, therefore, we are to progress at all, at least on the same lines that we have been doing since the last hundred years, this diminution in the rural population (which to us is almost synonymous with agricultural population) must be continually increasing. It is true this process of replacing agricultural labor may be carried too far. Look, for instance, at the case of England, where, in 1881, the percentage of urban on the total population was about 66.6 per cent. It is well known that the remainder, i. e., 33.4 per cent, was not wholly rural, much less agricultural. It is due to these circumstances mainly that agricultural labor is so highly paid out there, being much as 3 to 4 shillings per day per laborer. The problem which a highly civilized nation like the British has to deal with, is how to so regulate the different branches of labor as to bring to the country the greatest amount of wealth without seriously diminishing the amount of agricultural labor available. But as yet we Indians are as far from that state as are the heavens from the earth. What is important to us is the recognition of the fact that, with the progress of civilization, the relative proportion of our agricultural population must diminish, and that, as with us, there is no difference whatever between the agricultural laborer and the farmer, this diminution implies the withdrawal of so many men from the agricultural profession.

Now this disproportionate diminution of our agricultural population would mean a corresponding decrease in the extent of

our cultivated land unless we supposed—first, that the efficiency was observable amongst our peasant cultivators, or secondly, that man had the machinery to the necessary extent. The first, if correct, would, of course, show that the number of agricultural holdings, due to persons holding them, or the removal of particular holding was neutralized by an increase in larger holdings, or by a better management of the land. Any one, however, who has had to deal with a peasant, knows but too well that idleness has never been his line, and that he has always had as much work to do as he could do in consistency with his strength. Greater efficiency with him, therefore, implies greater strength, better machinery, or better cattle, the latter two items implying the possession of a larger capital than before. In the face of his extremely notorious poverty and absence of any evidence whatever of an increase in his physical strength, we must dismiss the first supposition as extremely unlikely. Besides that he has never introduced any improved machinery or any better cattle is a fact of history. Under these circumstances, the possession by him of surplus hands, i. e., of labour which he could spare, seems to us to be a groundless assumption. The question, therefore, of his improved efficiency falls to the ground. As to the second supposition, it has already been shown that the Bengal farmer never introduced any machinery by which any perceptible replacement of labor could take place, so far as the tillage of the soil are concerned. Nor do we know of any such improvement ever having taken place in any other way.

It thus appears that diminution of our agricultural population has been followed by a decrease of the acreage under cultivation. We need only refer to the experience of living men to prove that the reclamation of waste land for purposes of cultivation and the formation of *churns* in river-beds, together form but a small fraction of the quantity of arable land that has gone out of cultivation in Bengal—either being allowed to run to waste, or, having houses, manufactories, or other buildings, more or less expressive of social progress, built upon it.—*Indian Mirror*, August 22.

AN ALARMING DISEASE AFFLICTING A NUMEROUS CLASS.

THE disease commences with a slight derangement of the stomach, but if neglected, it in time involves the whole frame, embracing the kidneys, liver, pancreas, and in fact the entire glandular system; and the afflicted drag out a miserable existence until death gives relief from suffering. The disease is often mistaken for other complaints; but if the reader will ask himself the following questions, he will be able to determine whether he himself is one of the afflicted:—Have I distress, pain, or difficulty in breathing after eating? Is there a dull, heavy feeling, attended by drowsiness? Have the eyes a yellow tinge? Does thick sticky mucous gather about the gums and teeth in the morning, accompanied by a disagreeable taste? Is the tongue coated? Are there pain in the sides and back? Is there a fullness about the right side as if the liver were enlarging? Is there constipation? Is there vertigo or dizziness when rising suddenly from a horizontal position? Are the secretions from the kidneys scanty and highly coloured, with a deposit after standing? Does food ferment soon after eating, accompanied by flatulence or a belching of gas from the stomach? Is there frequent palpitation of the heart? These various symptoms may not be present at one time, but they torment the sufferer in turn as the dreadful disease progresses. If the case be one long standing, there will be a dry, hacking cough, attended after a time by expectoration. In very advanced stages the skin assumes a dirty, brownish appearance, and the hands and feet are covered by a cold sticky perspiration. As the liver and kidneys become more and more diseased, rheumatic pains appear, and the usual treatment proves entirely unavailing against this latter agonizing disorder. The origin of this malady is indigestion or dyspepsia, and a small quantity of the proper medicine will remove the disease if taken in its incipient stage. It is most important that the disease should be promptly and properly treated in its first stages, when a little medicine will effect a cure, and even when it has obtained a strong hold, the correct remedy should be persevered in until every vestige of the disease is eradicated, until the appetite has returned, and the digestive organs are restored to a healthy condition. The surest and most effectual remedy for this distressing complaint is "Seigel's Curative Syrup," a vegetable preparation, sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White, Limited, 17, Farringdon-road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

Market-Place, Pocklington, York, Oct. 2, 1882.

—Being a sufferer for years with dyspepsia in all its worst forms, and after expending pounds in medicines, I was at last persuaded to try Mother Seigel's Curative Syrup, and am thankful to say have derived more benefit from it than any other medicine I ever took, and would advise any one suffering from the same complaint to give it a trial; the results they would soon find out for themselves. If you like to make any use of this testimonial you are quite at liberty to do so.—Yours respectfully,

(Signed) R. TURNER.

Seigel's Operating Pills are the best family physic that has ever been discovered. They cleanse the bowels from all irritating substances, and leave them in a healthy condition. They cure constiveness.

St. Mary-street, Peterborough, Nov. 20, 1881.

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years with dyspepsia; but after a few doses of the Syrup, I found relief, and after taking two bottles of it I feel quite cured.

I am, Sir, yours truly,

Mr. A. J. WHITE.

WILLIAM BRENT.

Hensingham, Whitehaven, Oct. 16, 1882.

Mr. A. J. WHITE.—Dear Sir,—I was for some time afflicted with piles, and was advised to give Mother Seigel's Syrup a trial which I did. I am now happy to state that it has restored me to complete health.—I remain, yours respectfully,

(Signed) JOHN H. LIGHTFOOT.

August 15th, 1883.

Dear Sir,—I write to tell you that Mr. Henry Hillier, of Yatesbury, Wilts, informs me that he suffered from a severe form of indigestion for upwards of four years, and took no end of doctor's medicine without the slightest benefit, and declares Mother Seigel's Syrup which he got from me has saved his life.—Yours truly,

(Signed) N. WEBB,

Chemist, Calne.

September 8th, 1883.

Dear Sir,—I find the sale of Seigel's Syrup steadily increasing. All who have tried it speak very highly of its medicinal virtues; one customer describes it as a "Godsend to dyspeptic people." I always recommend it with confidence.—Faithfully yours,

(Signed)

VINCENT A. WILLS,

Chemist-Dentist,

Merthyr Tydvil.

Preston, Sept. 21st, 1883.

To Mr. A. J. WHITE.

My Dear Sir,—Your Syrup and Pills are still very popular

with my customers, many saying they are the best family medicines possible.

The other day a customer came for two bottles of Syrup and said, "Mother Seigel" had saved the life of his wife, and he added, "one of these bottles I am sending fifteen miles away to a friend who is very ill. I have much faith in it."

The sale keeps up wonderfully; in fact, one would fancy almost that the people were beginning to breakfast, dine, and sup on Mother Seigel's Syrup, the demand is so constant and the satisfaction so great.—I am, dear Sir, yours faithfully,

(Signed)

To A. J. WHITE, Esq.

(A)

HOLLOWAY'S PILLS.—Enfeebled Existence.—This medicine embraces every attribute required in a general and domestic remedy; it overturns the foundations of disease laid by defective food and impure air. In obstructions or congestions of the liver, lungs, bowels, or any other organs, these Pills are especially serviceable and eminently successful. They should be kept in readiness in every family, as they are a medicine without a fault for young persons and those of feeble constitutions. They never cause pain, or irritate the most sensitive nerves, or most tender bowels. Holloway's Pills are the best known purifiers of the blood, and the best promoters of absorption and secretion, and remove all poisonous and obnoxious matters from both solids and fluids.

FOR PRICKLY HEAT, CONSTIPATION, HEADACHE, BILIOUSNESS, CHOLERA, FEVERS, &c.

The testimony of Medical gentlemen has been unqualified in praise of

LAMPLOUGH'S PYRETIC SALINE,

As possessing elements most essential for the restoration and maintenance of health with perfect clearness of body and mind.

It is Effervescent & Tasteless; forming a most Invigorating, Vitalising & Refreshing Beverage.

Gives instant relief in HEADACHE, SEA or BILIOUS SICKNESS, CONSTIPATION, INDIGESTION, LASSITUDE, HEARTBURN, and FEVERISH COLDS; prevents and quickly cures the worst forms of TYPHUS, SCARLET, JUNGLE, and other FEVERS, SMALLPOX, MEASLES, and ERUPTIVE or SKIN COMPLAINTS, and various other altered conditions of the Blood. A valuable PREVENTIVE of DYSENTERY.

Dr. FROST:—"It affords genuine relief to mankind."

Dr. MORGAN:—"It furnishes the blood with its lost saline constituents."

Dr. SPARKS (Government Medical Inspector of Emigrants from the Port of London writes:—"I have great pleasure in bearing my cordial testimony to its efficacy."

GOVERNMENT OFFICIALS AND PLANTERS caring for the welfare of their employees should note its value as a specific in Fever Cases.

Dr. J. W. DOWLING and his family to state that Dr. W. STEVENS

the treatment of forty-two cases of Typhoid Fever cured the Fatal West India Fevers were dependent on

MAJESTY'S REPRESENTATIVE the GOVERNOR of SIERRA LEONE, writes:—"I am at present in the Pyrenean States. It is of great value, and I shall rejoice to hear it is in the hands of all Europeans visiting the Tropics."

RAHUL PINDER, PUNJAB, INDIA.—"We firmly believe that the use of your Pyretic Saline will do more to prevent fever than all the Quinine ever imported can cure."

Dr. TURLLEY.—"I found it act as a specific, in my experience and family, in the worst forms of Scarlet Fever, no other medicine being required."

Dr. B. GIBSON (formerly Physician to the London Hospital).—"Its usefulness in the treatment of disease having been confirmed by medical experience."

To be obtained of any Chemist or Drug Store, in Patent Glass-stoppered Bottles, at various prices. Please note in connection with the recently observed effects of the use of Citrate and other preparations of Magnesia that LAMPLOUGH'S PYRETIC SALINE is warranted not to contain Magnesia or any substance which would cause calculous or other earthy deposits.

H. LAMPLOUGH, 113, HOLBORN HILL, LONDON, E.C.

HEALTH FOR ALL!!!

HOLLOWAY'S PILLS & OINTMENT.

THE PILLS

Purify the Blood, correct all Disorders of the

LIVER, STOMACH, KIDNEYS, AND BOWELS.

They invigorate and restore to health Debilitated Constitutions, and are invaluable in all Complaints incidental to Females of all ages. For Children and the aged they are priceless.

THE OINTMENT

Is an infallible remedy for Bad Legs, Bad Breasts, Old Wounds, Sores and Ulcers. It is famous for Gout and Rheumatism. For disorders of the Chest it has no equal.

FOR SORE THROATS, BRONCHITIS, COUGHS, COLDS,

Glandular Swellings, and all Skin Diseases, it has no rival; and for contracted and stiff joints, it acts like a charm.

Manufactured only at THOMAS HOLLOWAY'S Establishment,

78, NEW OXFORD STREET (late 533, OXFORD STREET), LONDON.

And are sold at 1s. 1d., 2s. 6d., 4s. 6d., 11s., 22s., and 36s. each Box or Pot, and may be had of all Medicine Vendors throughout the World.

purchasers should look to the Label on the Pots and Boxes. If the address is not 533 Oxford Street, London, they are spurious.

INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.] CALCUTTA:—SATURDAY, SEPTEMBER 5, 1885. [No. 36.

Health, Crop and Weather Report.

[FOR THE WEEK ENDING 26TH AUGUST 1885.]

General Remarks.—Except in Malabar and Travancore, the rainfall during the past week in the Madras Presidency has been very slight. In Bellary heavy rain is urgently wanted for the dry crops, which are generally withering and are in a critical condition. More rain is also wanted in Ganjam, Kistna, Coimbatore, Tanjore and Madura. In Mysore little or no rain has fallen since the date of the last report. The young dry crops are reported to be withering, and agricultural operations have been retarded. Prospects are unsatisfactory in Tumkoor, Kolar, Kadur, Shimoga, and Mysore.

Good rain has fallen in most districts of the Bombay Presidency, but in Nasik, Poona, Ahmednugger, Sholapore, and Dharwar more is needed. In Sholapore especially the situation is unsatisfactory; very little *khari* is sown, and the season is now over. Fodder is scarce in several districts. In the Berars and in the Nizam's territories the season is favourable, and crop prospects are good. Rain has fallen throughout the Central India and Rajpootana States, and agricultural prospects are on the whole very satisfactory.

In the Central Provinces the weather continues favourable for the crops, which are progressing satisfactorily. ~~much needed in Saugor and Hoshungabad.~~ Except in two districts, rain has been general in the ~~United Provinces~~ *khari* prospects are favorable. Heavy rain has fallen in many districts in the North-Western Provinces and Oudh, causing injury to crops on low lands. Agricultural prospects are fair.

Rain has been general throughout Bengal, but excessive in Moorehobad, Burdwan, Haoribagh, and Midnapore. Considerable injury has been done to both *aus* and *aman* crops in Burdwan, and to the *bhadoi* crops in Moorehobad and in parts of Behar. Elsewhere agricultural prospects are favourable, and the *aus* harvest is yielding a fair outturn. The weather is reasonable in Assam, but in Sylhet more rain is wanted. Transplanting of *sali* crops continues.

Heavy rain reported from British Burmah, where ploughing and transplanting continues.

Cholera is chiefly prevalent in the Madras and Bombay Presidencies, and in Raipore in the Central Provinces. Elsewhere the public health is generally fair.

Prices are generally steady, except in the Punjab, where they are fluctuating.

Madras.—General prospects fair, improved in Bellary and Anantapore; crops are in very critical condition and in some villages already past revival; in Madura and Coimbatore reported to be discouraging.

Bombay.—Good rain in most districts, more wanted in parts of the Deccan and Southern Mahratta Country, especially in Sholapore. Crops withering for want of rain in two talukas of Sholapore and injured by excessive rain in parts of Gujarat and by insects in parts of Kurrachi and Upper Sind Frontier; fodder scarce in parts of Khandesh, Sholapore, Ahmednugger, Nasik, Bijapore, and Belgaum. Cholera general; fever and cattle-disease in parts of eight, and small-pox in parts of three districts.

Bengal.—Rain has been general throughout the province, but excessive in some parts. In places in the Burdwan division floods are doing considerable injury to both *aus* and *aman* crops; much damage has also been caused by floods to *bhadoi* crops in Moorehobad, and on low ~~Deccan~~ lands, and in parts of Behar; elsewhere agricultural prospects are favourable; *aus* harvest is promising and is yielding a fair outturn; transplanting is still progressing in Behar. Prices of rice continues high. Public health generally fair.

N.-W. Provinces and Oudh.—Rainfall general, except in Dera Ismail Khan and Peshawar districts. Fever in the Peshawar district, elsewhere the health is good. *Khari* prospects favourable. Prices of food grains rising in the Blakot and Shahpore districts, falling in Hissar and Ferozepore, and generally stationary elsewhere.

Central Provinces.—Except in Saugor, where a break is much needed, the weather has been very favourable for the crops; showers alternating with bright sunshine. Cholera continues severe in Raipore.

British Burmah.—Cholera prevalent in one district, slight in three districts, elsewhere health good, cattle disease severe in two districts, slight in five districts, elsewhere health of cattle good. Ploughing and

transplanting progressing. The rain has been exceedingly heavy in all districts, except Promo, and slight damage to crops from floods is reported in two districts.

Assam.—Weather reasonable. Transplantation of *sali dhia* continues; prospects of tea good. Fever and bowel-complaints prevalent, otherwise public health good.

Mysore and Coorg.—Young dry crops reported to be withering; agricultural operations retarded and uneasiness prevalent; in Tumkoor prospects reported as critical in Kolar as uncertain, in Kadur lowlands as unfavourable, in parts of Sholaga lowlands rice crops need heavy rain; water and fodder becoming scanty. Coffee and cardamom crops in good condition. Prices of food-grains slightly fallen. Prospects of season and public health good.

Bevar and Hyderbad.—*Ahi* sowing concluded; weeding of *khari* crops commenced. General health good. Prices—wheat 14½, coarse rice 12½, white *juari* 19½, yellow *juari* 22½, and *tur* 15½ acoers per current siona rupee.

Central India States.—Prices falling. Crops thriving. Weather clear. Health good.

Rajpootana.—Weather cloudy and rainy. Crop prospects good. Slight cholera and fever prevalent in parts; otherwise health good.

Nepal.—Weather cool. Prospects good. Cholera disappearing.

Editorial Notes.

THE question of the possibility of Artesian wells existing in Vizianagram having been re-opened, Dr. Wm. KING, of the Geological Survey of India, has been deputed to report on the subject for the Madras Government, and he leaves Calcutta for Bimlipatam on the 5th instant (this day).

**

THE prices realised at the Opium Sale on the 2nd instant are considerably above the budget estimates. The prices were as follow:—

			Average.
Behar	...	Rs. 1,255 to Rs. 1,295	Rs. 1,287
Benares	...	Rs. 1,255 to Rs. 1,270	Rs. 1,262

The general average upon the 4,166 chests sold was Rs. 1,274.

**

IN another column will be found the orders issued by the Government of India, in respect to the rules to be observed generally during the prevalence of scarcity. Paragraph 3 of the Government of India letter is important, inasmuch as it recognises the Government responsibility for the measures taken to meet famine or scarcity.

**

THE supplement to the last *British Burmah Gazette* contains a valuable paper by Mr. J. E. Bridges, Director of Agriculture, British Burmah, on sugarcane and sugar trade in that province, and brings to light some facts not previously known on this subject. We have read the paper with much interest, and reproduce it *in extenso* elsewhere for the benefit of our readers.

**

IN the same issue of the *British Burmah Gazette* is a report on minerals in Tenasserim by Mr. R. Romanis, the chemical examiner, which we also reproduce, as the mining industries in Burmah are attracting much attention just now. A company has already been formed to work the lead mines of the province, and others may soon be following suit to work other mines.

The quantity of cotton exported from British Burmah during the month of July 1885 was 7,035 cwts, amounting in value to Rs. 1,57,406. The export was confined to the port of Rangoon, and the destination was chiefly to foreign ports out of India. These figures show that the cotton trade of the province is no insignificant factor.

.

SOME time back we noticed an American invention which claimed the merit of refining sugar by electricity. We did not quite believe in the *bona fides* of this novel process, but gave the information for what it was worth. We now see from an article in the last number of the *Sugar Cane* to hand, together with the connected papers on which the article is founded, that the invention may be regarded as a *fait accompli*. This will certainly create a revolution in sugar-refining; and if the whole thing is not a gigantic fraud, this is another triumph for the inventive genius of our trans-atlantic cousins. The article from *Sugar Cane* will be found among our selections.

.

We regret to say that a mistake unfortunately crept into our columns in the issue of June 20th last, with respect to the grant of a C. I. E. to Mr. C. K. Mudilair of Madras. On looking over the list of birthday honours distributed last June, we find that it is Mr. P. S. Ramaswamy Mudilair, Avargal, of Madras, upon whom the honour has been conferred, and not Mr. C. Krishnaaswamy Mudilair, the recipient of the gold medal from the Government of Madras for agricultural improvements. The error should have been rectified before had we known it. Only within the last few days it has been pointed out to us, and we hasten to make the correction.

.

The total imports entered at the several ports of British Burmah, during the month of July 1885, amounted in value to Rs. 48,26,554, divided as follows:—

Foreign ports out of India	...	25,66,343
British " in other provinces	...	18,63,921
" " within the "	...	3,05,417
Indian " not British	...	49,473

There were no importations of gold, but of silver there were:—

For Government	...	60,000
" private parties	...	20,600

The exports during the same period amounted to Rs. 77,01,049 in value, and were as follows:—

		Rs.
Foreign ports out of India	...	51,83,866
British " in other provinces	...	13,75,974
" " within the "	...	3,63,399
Indian " not British	...	1,72,810

There was no gold exported, and the silver, which amounted to Rs. 1,15,413, was entirely confined to private parties. It will thus be seen that the exports of articles exceeded the imports by Rs. 28,74,495, and the silver exports over imports amounted to Rs. 44,613.

.

We understand that his Honor the Lieutenant-Governor of the N.-W. Provinces and Oudh has sanctioned a proposal to have an Exhibition of Arts and Manufactures in Lucknow during the last week of November. It is intended to collect the best specimens of the principal art manufactures of the united provinces, and the local Government has not only been liberal in making a grant for prizes, but has expressed its intention of purchasing the best articles for the Indo-Colonial Exhibition, London, 1889. These specimens will be the principal features of the Exhibition, but a section will be added for Oudh arts and industries of a humbler description. The addition of a Loan Exhibition of articles of Oriental Art complete the scheme. The Municipal board has placed Rs. 5,000 at the disposal of the Exhibition Committee, and we believe the British Indian Association will not be backward in contributing to so useful an undertaking.

.

A MEETING, consisting of the leading ryots of Atur and surrounding villages, together with the taluk officials, was held

recently at the public chattram, for the purpose of establishing an agricultural farm, where agricultural pursuits may be tried on new and improved methods. The Tehsildar, Mr. Ram Seshya Iyer, B.A., was voted to the chair. He explained the advantages to be derived by the introduction of European ploughs, irrigating machines, &c. He also earnestly desired his hearers to give the innovation (for they deemed it nothing else) a fair and efficient trial, and judge the results by the material advantages accruing therefrom. The address had the desired effect, for many ryots expressed their willingness to join, and were enrolled as members. Great credit is due to Mr. Ram Seshya for his endeavours to establish this association, as Atur is a taluk in the Salem district where agriculture is the main pursuit of its inhabitants, so it presents a fair field for the development of the new method.

.

About three weeks back we noticed Mr. Cabaniss' note on cigar-making in Burmah, and thought it a very practical paper. We now read the following paragraph in the *Rangoon Gazette*, from which it would appear that much success has attended the growing and curing of tobacco on the Government farm at Kyouktan:—“We are indebted to Mr. Cabaniss, Assistant Director of Agriculture, for a sample tin of cut tobacco grown at the Government farm at Kyouktan from Havannah seed, which has a fine delicate aroma and smokes very mild. It shows what can be done in Burmah for the development of the tobacco industry by adopting proper systems of cultivation and curing. It will take many years, however, to get Burmans to adopt European ideas and methods which, though yielding a better return and a finer article, are yet too troublesome to the Burman mind. But Government should direct its efforts to inducing Chinamen, who are more patient and painstaking, to go to the tobacco cultivation.”

.

The Director of Agriculture in Madras has received the sanction of the local Government to the publication of forecasts of the harvest prospects of certain food-grains and special crops. We suppose these forecasts will be somewhat on the lines of those published in respect to wheat by the Director of Agriculture and Commerce, N.-W. Provinces and Oudh. To sum up briefly, it is intended that each year four forecasts should be issued detailing the area sown, as compared with the average area of the previous five years' sowings, and also four condition and outturn reports dealing with the state and expected outturn of the crops, valued in annas. The first reports are to be issued as soon as possible after the first day of September, December, March, and April, respectively. These reports would deal with the sowings of the early crops, such as paddy, cholam,umbu, ragi, and indigo; the second and the third with the sowings of the later crops of paddy, cholam, ragi, cotton, and late indigo, and the last with sugarcane. The condition and outturn reports are to be issued after the 1st of October, January, April, and May, dealing principally with the crops mentioned in the area report of the previous month; but the June report would also contain the final summary on the harvest of the year for all crops.

.

The methods by which the Director proposes to calculate the standard of the different crops are, in our opinion, somewhat round-about. We would recommend the Southern Presidency to take the wheat forecasts of the N.-W. Provinces as models to work upon. A review of the last and final forecast will be found in the *Indian Agriculturist* of June 27th, 1885, page 305. We may observe that these forecasts are thoroughly practical, and what is of much more importance, reliable. The Government of the N.-W. Provinces and Oudh is remarkable for the accuracy of its agricultural statistics, and the advanced stage of its agricultural operations. But anything that the Madras Government may undertake in this connection will be a happy change, and an improvement upon the season reports and telegrams issued at present. The chief point, however, to be borne in mind is punctuality, and unless issued at the earliest possible dates, the forecasts will lose half their value.

The outlook of the wheat crop in America has been one of anxiety, but from the last report (July) of the Department of Agriculture, we see that the month has been favourable to the development of winter wheat, and a slight improvement is indicated which advances the general average two or three points, i.e. from 62 to nearly 65. The corn crop, however, which is the great crop of the country, shows an increase of 6 per cent. Very few States show any decrease. In many cases the failure of wheat has been made up by the planting of corn for the winter supply; wheatlands have therefore been largely utilized. In fact, the condition of corn is reported as being higher than in any year since 1880, except the last. The condition of oats continues high and promises a large crop. The average is 97, an increase of three points since the last reports. Potatoes show the same condition and average; while the area under sorghum has declined in nearly all the States where it is grown, the low price of sugar and syrup are said to have had a discouraging effect. Cotton has shown an improvement since June, and the average condition has advanced from 92 to 96. The condition of grasses and pastures is reported as favourable. The fruit crops encourage a hope of a favourable season. On the whole, prospects now look hopeful.

.

The following remark by Mr. R. Romanis, Chemical Examiner, British Burmah, on the state of agriculture in Tenasserim, is worth reading. It is *multum in parvo*, and contains a whole mine of important information:—"The most remarkable feature of the province is the large proportion of land under garden cultivation. The orange gardens of Kyaukse on the Gyaling are noted for their fertility, and for the Salween and Gyaling are lined with plantain, areca, palm, and coconut. The oranges and durians exported to Rangoon and elsewhere are grown principally along the road between Moulmein and Amherst. The small export of rice from Moulmein, in proportion to the area under cultivation, is explained partly by this great proportion of garden ground. It is said that a good deal of rice goes in cargo boats and small country craft along the coast, of which no note is taken. The large population engaged in the timber trade above the frontier must absorb a certain proportion. I noticed a large quantity of tobacco growing along the banks of the Doudami river. The soil here probably resembles that in which the Kyaukkyi tobacco is grown. On the whole I think the Tenasserim province a more favourable field for agricultural experiments than Pegu. The Shans and Taungthas are accustomed to grow a variety of crops, and are more likely to adopt new things than the Burmans of Pegu."

The concluding paragraph we regard as most important, and hope soon to hear that the Chief Commissioner has taken steps to initiate agricultural experiments in this *El-toronto*, somewhat on the principle of those carried on in Mergui and the Arakan Hill tracts, which were noticed by us very recently.

.

A short time back we noticed the energetic enterprise of the proprietors of the Murree Brewery Company in opening a Brewery in Ceylon. We now learn from the *Times of Ceylon* that the alterations and extensions which have been going on upon the brewery buildings and premises for some months past are now nearly completed, and the manager confidently expects to begin operation within a month from the present time. All the works are being fitted up with the latest improvements known to the trade, similar in fact to those large establishments in various parts of India which have been of late years worked so successfully by the Murree Brewery Company, of which this is a branch. This Company has given the Indian military authorities so much satisfaction that it has now the practical monopoly of the beer supply for the troops throughout the presidencies. The Company hope to obtain the contract for the supply of the troops in British Burmah, for which application has been made; and it is their intention, if successful—as there is very little doubt they will be—to supply that place from their brewery at Nuwara Eliya. About 3,000 hhd.

would be required annually, so that the railway would directly benefit by the traffic of the raw material up and the manufactured article down. When Mr. Whympere was in Ceylon recently we believe he interviewed Mr. Pearce, with a view to obtaining some concession in the way of transport, but without success; that rigid red-tapist as usual not seeing his way to make any relaxation in existing rates. We hope, however, that the "careful consideration" into which Mr. Pearce recently stated he had taken the question of these self-same exorbitant rates will have the effect of producing an extensive lowering thereof. Such an enterprise as a local brewery at Nuwara Eliya, should be encouraged as much as possible, and we have no doubt that a proper representation on the subject will have due effect. Mr. Howard, the local manager of the brewery, has not all the machinery and appliances up in Nuwara Eliya, but most are in position, and we hope to hear that the first brew shortly to be undertaken is a successful one, for no pains or expense have been spared by the Company to provide for all contingencies.

Forest Conservancy in the Bombay Presidency has formed the subject of much discussion lately, and the appointment of a Forest Commission to enquire into the grievances of the people has been the result. From a telegram received in Calcutta we learn that Lord Reay opened the Forest Commission on the 27th ultimo at Poona with a very remarkable address, in the course of which he laid down the lines upon which the Commission would have to work. The members of the Civil Service, on Commission, he said, were not acting as Government representatives, but had been appointed to give their own views and the result of their own experience. He would not enter into the causes which had led to the appointment of the Commission, but it was a remarkable fact that both the late and the present Secretary of State had approved of the institution of such an enquiry, and that the sanction of the Viceroy had also been obtained for it. Since he had been charged with his present duties, the matter had been a constant source of anxiety to him. Agricultural problems had always struck him as peculiarly interesting, and the more one looked into the agricultural systems of various countries, the more one became convinced that over-legislation in agricultural matters was a mistake. Agricultural centralization would certainly lead to disastrous consequences. Local wants, customs, and systems, and village tenures had best not be wantonly disturbed, unless very good cause was shown. He approached agricultural questions with a strong bias in favour of the agriculturist, as every Scotchman would have been accustomed in Scotland to give the most respectful consideration to the experience of shrewd farmers, shepherds, and farm servants. He believed that if the forest conservancy tended to increase the supply of fodder and fuel for the people of the country, the enterprise would meet with support and have their sympathy. He also believed that hardships could be mitigated. His chief object was to substitute co-operation for antagonism, confidence for distrust, contentment for disturbance. The Commission, he had no doubt, would assist the Government in its endeavours to remove legitimate grievances. They would assist the Government in preventing the wanton destruction of timber,—a proceeding utterly unwarrantable, and most demoralising and injurious to national interests. A strong Government did not stand in need of exceptional measures to put a stop to such vandalism. The Commission would strengthen, not weaken, the ultimate action of the Government.

.

Mr. Cabanis, Assistant Director of Agriculture, British Burmah, has been trying his hand at plough-improving in Burmah with much success, according to the *Rangoon Gazette*, which says:—"We have seen a model of an improved Burman *Ton-kan* or plough (used for ploughing paddy fields) devised by Mr. Cabanis, who, in watching the working of one of these primitive implements, observed that a very great deal of time was lost by the ploughmen having every now and then to stop and clear the prongs of his plough from the long grass which

clogged or entangled the prongs of his plough. Mr. Cabaniss' *Tone-don* has a reversible row of prongs, set in a roller made of wood. When one set gets clogged, by raising the handle of the plough the roller goes round, and the spare row of prongs takes the place of the other, which gets cleaned during the change; the handle of the plough is lowered and the ploughing continued without more than 3 seconds' loss of time. Mr. Cabaniss' invention, or rather improvement, is as ingenious as it is simple; and the Burmese who tried two or three of the ploughs constructed on the improved plan are quite charmed with them, as they not only saved much time and trouble, but they are able to adjust the prongs to any angle by means of the plough-handle as the plough journeys along.

In *Cassell's Popular Gardening*, we came across the following practical instructions for raising orchids by seed:—The seeds of orchids are sown in pots filled with crocks and growing sphagnum, or better still, upon the sphagnum growing about other orchids. It is necessary that the seeds should be sown immediately on their becoming ripe as, owing to their smallness and extreme delicacy, they do not retain vitality long. They should be scattered upon the sphagnum and then left to themselves, the treatment required by the plant about which they are sown being such as will afford them all they need. To prevent the risk of washing the seeds away with water, the top and sphagnum upon which they are sown should be dipped a little way in water so as to allow it to soak upwards, and not watered over-head. The time seeds of orchids take to germinate varies, according to the species, from three to twelve months. Seeds of *Disa grandiflora* are perhaps the easiest managed among orchids; they may be sown upon a mixture of chopped sphagnum and peat. Numerous varieties of this beautiful orchid have been obtained from seeds raised in this country. Germination having taken place, and the seedlings being large enough to handle safely, they may be removed from the seed-pot and planted in tiny pots of chopped sphagnum and crock-dust. To guard against drought and danger to the seedlings, it will be found a good plan to place a number of these tiny pots together in a flat pan, filling up between the pots with sphagnum; these pans may then be suspended near the glass in a shaded house of the temperature suited to the requirements of each kind of orchid. Patience of no ordinary kind must be possessed by anyone attempting the raising of orchids from seeds, as it takes a very long time for most of the kinds to arrive at a flowering condition. In the case of cattleyas, for instance, it generally takes from seven to ten years, and sometimes even longer, to grow a plant from seed on to its first flowering.

Ceylon teas hold a high place in the English markets, and the following remarks by Mr. H. K. Rutherford on the yield of acreage under tea in that island, will be read with interest:—“This subject has not, as far as I am aware, been entered into by others, at least I cannot find any record of it in the tea literature of Ceylon. Many individual estates have been quoted as producing heavy crops, and proprietors and superintendents have vouched for the large yields which are being obtained per acre of certain estates. When however we compare the acreage under tea in the island, with the amount of our exports of the product, it does not up to date show that the average yield of our estates is likely to exceed that of India for many years to come. The last published returns of Indian Tea Companies, representing 42,355 acres, showed a return of 311 lbs. per acre, and it will be seen with reference to the following statement that we have only reached an average of 210 lbs. per acre, and will not exceed this before 1888. This of course we attribute to our trees not being matured, but look forward to, at any rate, as good a yield per acre as India in the future. In my opinion, it is doubtful if our average yield will exceed that of India to any appreciable extent. I think, we can, with a fair amount of correctness, foretell what the yield of our acreage will be up to 1898, but any calculations going beyond that date would not come within the pale of accuracy or practical usefulness. I have for the year 1888 estimated a yield of 20½ million lbs., and I think it is reasonable to suppose that we shall obtain in that year an

average of 210 lbs. per acre off 90,000 acres in bearing. Mr. W. Anderson in March last published a statement showing that there were 85,800 acres under tea in Ceylon at the end of 1884. I am of opinion this is somewhat in excess of the actual acreage at that date, and I prefer to take 72,000 acres as being nearer the correct amount.—No statistics are yet available for the acreage planted this year, but I think in taking the total at 102,000 acres to the end of 1885, I shall not have exceeded the actual amount planted. With regard to the local consumption there is no data available to enable us to say with certainty what quantity is consumed, but I find in 1861 there were 87,000 lbs. of China tea imported into the island, and when it is considered, that the burgher and native population, who a few years ago drank coffee, now consume tea, I think it is reasonable to suppose that the local consumption will rise to 200,000 lbs. by 1888.”

It seems to have been fully proved that experiments with fibre in the Madras presidency have, in the majority of cases, resulted in failure. The report of Mr. Price, the Acting Director of Revenue Settlement and Agriculture, Madras, bears out this conviction. It appears that in 1883 a sum of Rs. 2,000 was provided for the “improvement of agriculture and trade,” more than half of which was devoted to experiments with fibres. In five different districts attempts were made to extract fibre, and in each case they proved financial failures. The fibres experimented upon were *aloe*, *sun hemp*, *sansiviera zeylanica*, *agave vivipara*, *agave Americana*, *helicteres isora*, and *lasiosiphon erioscephalum*. It is needless to go into details, as in every single case the fibre was collected and prepared as valueless as valued in the markets. We took occasion to observe a short time back that it was a waste of time, labour and money to attempt to get at any satisfactory understanding of the value of these fibres, as the experiments were conducted with thoroughness. In this opinion we are fully borne out by the testimony of Mr. Price himself, who concludes his report with the following very sensible remarks:—

I take advantage of this opportunity to submit, for consideration, the futility of the amateur experiments with fibres which are, from time to time, carried out by Revenue officers in different parts of this presidency. The results, as far as my knowledge goes, have, invariably, been financial failures. It could hardly be otherwise when the fibre has to be prepared by hand and by unskilled workmen. * * * We know most of the fibres: we know the value of a large number of them. What is now required is certainty as to the supply—naturally or by cultivation—of the raw material and means for the cheap, rapid, and efficient preparation of the fibres. As regards the former point, it is, in the case of certain fibres, e.g., *aloe*, the *calotropis*, *fourcroya*, *sansiviera*, &c., assured. The latter is that which still awaits a satisfactory solution. Until this is arrived at, it is, I submit, throwing away time, trouble and money to produce by hand indifferent samples of fibres which are, owing to the method of their preparation, costly, and which being indifferently got up, are priced at considerably below their proper value.

There is, no doubt, a mine of wealth in the fibres of this presidency if properly worked. I venture to throw out the suggestion that the time has arrived when the subject might well be placed under a specialist, and be taken in hand as that of mineralogy has recently been. The most energetic and zealous of Collectors can really do very little. They are overburdened with other work, and have to leave details much with subordinates, and few, if any, have any but the most superficial knowledge of fibres and the proper methods of preparing them, even after the native fashion.

The head of the Agricultural Department, a gentleman of much varied experience, expresses himself as above, and it is therefore somewhat disappointing to find that the Government of Madras, with Mr. W. Wilson (the late Director of Agriculture) as Revenue Secretary, should take a different view of the question. This is what the Government says:—

With reference to the concluding paragraph of Mr. Price's letter, the Government observe that the problem of cheap, rapid, and efficient preparation of fibres is not one which can be solved by the creation of a special Government agency apart from the Agricultural Department. It is a question for inventive genius

and engineering skill, and the prospective profits of a successful invention seem sufficiently bright to encourage private investigation in this direction. It is noted that the prize of Rs. 2,000 offered last year by the Government of Bengal was awarded at the Calcutta competition to Messrs. Deane and Ellwood's Universal Fibre-cleaning Machine, the working of which was found to be "rapid and efficient." The Government concur in the opinion expressed by the Bengal Government that the further question, whether this or some other machine can be profitably introduced into this country, "may well be left to be decided by the commercial public."

To this we reply that, if the introduction into this country of a fibre-decorticating machine "may well be left to be decided by the commercial public," what need is there of experimenting with fibres, spending large sums of money on them, taking up the time of Collectors and other officers unnecessarily, sending specimens to England for valuation, &c., all with ultimate loss? To ascertain the market value of any particular fibre, it must be prepared so as to meet the requirements of the market, and at the lowest possible cost, otherwise the experiment is utterly worthless. It therefore follows that, to prepare any fibre with this end in view, there must be a specialist at the helm, and the best machinery available for the purpose. The trade requires facts and figures, and a technical analysis of experiments; and if the Government mean to encourage trade and private enterprise, it can serve no useful purpose in attempting to do so by half-measures.

THE INDIAN COAL MINES.

MR. JOSEPH CHATER, Esq., Superintendent of Messrs. APGAR and Co.'s Collieries at Setarampore, has undertaken to answer an enquiry as to the need of legislation on the part of Government, in connection with the Indian Coal Mines. His reply which forms a neat little brochure,* printed by Messrs. NEWMAN & Co., in the well-known style of the CAYTON Steam Printing Works, is the substance of a paper prepared for a meeting of the Bengal Mine Managers, held at Raneegunge in July 1884, when the subject was brought under discussion at the requisition of the executive, which called for an expression of opinion from those most concerned, as to the advisability or otherwise of enactments to regulate the coal workings. Mr. CHATER deals with the matter exhaustively, eliciting logical conclusions which we think carry conviction with them. He discusses the principal causes that led to legislative 'mining' enactments in England, and shows that they have no parallel in Indian mining. For instance, it may not be "generally known that previous to 1775, the Scottish colliers and their wives and children, if they assisted for a certain period at a coal work, became the property of the coal-master, and were transferable with the colliery, in the same manner as the slaves in the West Indian estates were held to be—property transferable on sale!" Mr. CHATER adds that it was only in June 1790, that colliers were placed in the same position as other labourers, with freedom to exercise their trade. He continues the historical notice of the growth and vicissitudes of the British industry, touching upon the exactions of the masters and the consequent revolt of the miners, which, coupled with the vast development of operations in later years, imperatively called for reform. The change was further accelerated by the disasters in mining assuming such large proportions as to enforce State intervention, with the view of preventing the then too frequent occurrence of such terrible accidents as the Hartly Colliery and other catastrophes. Mr. CHATER shows that the factors which produce such sacrifice of life, do not exist in Indian mining; that the Indian miner undergoes comparatively no risk, and is peculiarly well off. He adds, on this latter head, that the Indian miner is satisfied with his wages, which have advanced 50 per cent since mining became recognized as an industry in the country, and that he is thus able to earn considerably more than labourers in other callings, due not to his own seeking, but to the "result of competition." Mr. CHATER

attributes the present depression in the Indian coal trade, to "the unfair and continued competition of Government in the open market," because of the high freight to which Indian coal is subject, thereby rendering competition with foreign supplies impossible: because of the increasing imports of English coal into the country, which, by the liberal interpretation of a recent Government resolution, should not be allowed to enter our ports. That resolution laid it down that in future all public requirements, *re* stores, &c., should be confined as much as possible to indigenous sources. Yet what do we see? A culpable disregard of the spirit of the resolution on the part of those who have the disposal of State contracts, or power of making State purchases." This is a matter to which we would call the study of the authorities, likewise to the complaint that while every important branch of industry has received full attention by the local Government, the "mines" only receive a half-dozen lines in the Administrative Report in the place of the statistical statements called for from the owners of the collieries. This complaint is well founded. Mr. CHATER adduces facts and figures to demonstrate the inutility of the proposed appointment of a Government Inspector, and considers that the existing law is sufficient to meet any difficulties that may arise in connection with Indian mining, for many years yet to come. Similar appointments in England have not proved an unqualified success, and they would be worse than useless in this country. He says: "There being no gas in the mines of this district, and one pit to every acre of ground mined, artificial ventilation unnecessary, and inspection on that score a superfluity." The appointment would therefore be a sinecure. Speaking generally, Mr. CHATER says that legislation on the same lines as the British Mines Regulation Act, would, notwithstanding its beneficial and simple enactments, be incomprehensible to those for whom it was intended, and, if it did not "retard the progress of the industry, would do it very little good. If ever introduced, then all will be chaos and confusion." The why and wherefore are elaborately epitomised in the following excerpt, which embodies the views of the majority of those best qualified to form an opinion on the subject in this part of India:—

Considering the present harmonious relations between the employer and employed; the perfect freedom of action the latter enjoy under the former; the high rate of wages now paid for mining labour; the almost total absence of accident; and accidental deaths from roof falls, foundations, and other causes; the perfect immunity of the Indian mines from dangerous and explosive gases, rendering artificial ventilation unnecessary; the insignificance of the present Indian coal output, and the comparative nascent condition of the mining industry in the country, the time has not yet arrived for legislation in the manner proposed by the executive.

This is a forcible conclusion to a very interesting pamphlet, the practical value and public import of which cannot be over-estimated. It demands the consideration of the authorities, and will be welcome on all sides as the first attempt of its kind, and as the most valuable contribution that has yet been made to the literature of Indian Mining.

SUGARCANE CULTIVATION IN INDIA.

THE following extract from a letter received from Mr. Burrows, of Behen, has been courteously placed at our disposal by the Director of Agriculture, Bengal, and we publish it, as it will be found very useful at the present time:—

The usual Indian method of cane culture may be called *broadcast* as opposed to *planting*, as the term is understood by European and American planters. The difference in results may be approximately obtained by asking any ryot the difference in produce between *chattera* and *roap dhun* (broadcast and planted.)

The root of the sugarcane is a small collection of thin fibres or rootlets, there is no tap root. On these depend the health and vigour of the plant with its long succulent stem and succession of long broad leaves; it should, therefore, be placed in the best possible condition to enable it effectually to meet the heavy demand on it.

By the native method the root is on or near the surface of the ground. The field gets 12 or 14 surface ploughings giving

* The Indian Coal Mines: Is legislation necessary to regulate their workings? By Joseph Chater, F.S.S., APGAR's Collieries, Setarampore. Calcutta: W. Newman and Co. Ltd. : 1885.

a seed bed only four or five inches deep. The little manure (if any is given) is scattered irregularly over the surface, a plough goes round the field in a continually decreasing circle, and the cuttings are dropped into the shallow track so made. There may be a little manure where they fall, or there may not be any. The cuttings are covered with about three inches of earth by a piece of wood drawn over the surface, a man or two standing on it, each supporting himself by holding the tail of the bullock in front of him. This surface covering soon dries; the surface is then loosened a little by the hoe, the roots being carefully avoided. A little manure may now be placed round each plant by hand, and water is let on till the field is submerged or water-logged, thus sealing up the roots from air in plastic clay or loam compressed by the downward course of the water, and hardening as it dries. As the hoe avoids the roots, the compression of the soil around them increases just where it should be most friable. The hoeing is repeated about three times, followed by a *melons* watering, that is, till the ground is water-logged each time. When the plants reach a certain height, and the leaves begin to shade the field, hoeing is stopped, and as they grow, being close together with no regularity, a thick jungle is the result excluding sun and free circulation of air. Considering the nature of the plant and the work its root has to do, this treatment of it is most irrational.

In Mauritius, West Indies, and other places where cane cultivation is under European supervision, the cuttings or seedlings are laid at least nine inches under the surface of the ground, either in carefully-made rectangular oblong holes in rows three and-a-half or four feet apart, or in continuous channels or furrows made by hoe; or double mould board plough, the bottom being flat, and eight or nine inches wide, that is, wide enough to receive three cuttings placed some distance from each other. A field planted in this way will take as many cuttings as are usually put in by the native method. The space between the rows need not be ploughed, only cleaned of weeds by hoe, these are left on the ground, and are covered by the earth from the channels or holes.

Previous to planting the cuttings, manure in proper quantity is spread over the bottom of the channels and mixed with a little earth. On, or in this, the cuttings are laid end to end either in single, double, or triple rows as the width of the bottom may allow, and covered by hand with about three inches of earth. The "hole" system is used in Mauritius, the ground is hilly and undulating, rain is frequent, and each hole retains what may fall into it. In India where irrigation is necessary, the channel or deep furrow method is best. After some days the surface of the soil in the bottom of the channels is loosened by hand. This may be done by women or children, whereas the hoeing of the ryot's field has to be done by men. If water is now necessary, a little is allowed to flow from one end of the channel to the other, and then shut off. As the plants rise, more earth is filled in around them with a little manure where it may be needed; the loosening of the surface, watering and filling in is repeated till the channel is filled; after which, as the plants grow, the earth is drawn from the spaces between the rows and heaped round the roots till a ridge is formed at least nine inches high over the original surface. Subsequent irrigation is given in the hollows between the ridges, the water not being allowed to reach the top of the ridges by four or five inches, which are thus left friable, and open for the action of the air and expansion of the roots.

Our ryots have for years seen and acknowledged the considerable economy of labour, water, and manure in this method as compared with their own. They have also seen the common *mongra* cans of the district so improved that they had to be assured it was nothing else, yet none of them have had the enterprise to adopt it, though several among them have been at work on the cane fields of the West Indies and Mauritius, and know the method and its results.

Cane culture should be more of the nature of garden than field cultivation, and if done with a reasonable consideration of the nature and necessities of the plant, a third of the land, now yearly devoted to cane, could be put under other crops with no falling off in the weight of sugar produced.

The industry, as a whole, and in its details, from the preparation of the land till the crude produce is ready for the market, is in a very backward and wasteful condition; there is no reason except the inertia of the ryot why this should be so. This might be overcome, and a better rate opened out by some sustained effort on the part of Government, probably a graduated set of prizes for the best cane fields cultivated with reference to the nature and requirements of the plant. We know by experience they understand what this means, when explained to them in terms with which they are familiar.

THE VALUE OF EXHIBITIONS.

ACCORDING to some poetical thinkers, Exhibitions are the "Festivals of Peace," while the matter-of-fact are disposed to view them as gigantic "shows" of varied interests. Be that as it may, there can be no doubt that these institutions are now a recognized necessity of the times. Notwithstanding their recent growth, they already embrace a very extensive sphere of utility, for all classes of the community are interested in their extremely practical and intelligible mission—to materially influence for the better the future welfare of both people and country by stimulating industrial competition. They are the means of comparing the products of manufactures and for general instruction. They offer very substantial encouragement to the inventor, and exercise a very powerful influence on trade. They have an educational effect upon all classes, and as a medium of publicity, are immeasurably more efficacious than newspaper advertising. They were inaugurated in 1851 the Great Exhibition of that year being the forerunner, and the leader of all those which have been held since. In regard to that "show," it was asserted that it would have been the study of a life-time to see all that it contained. From general subjects, these objects have now commenced to be devoted to special aims;—hence, we find, "Naval," "Fisheries," "Health," and "Forestry" exhibitions occurring in England alone, but of an international character, and a host of minor ones repeated *ad nauseum*. Without going far for the practical results of such gatherings, we have the wonderful success of the Calcutta International Exhibition of 1883-84 fresh before us, due to the energy and intelligence of a stranger, M. Jules Joubert. This Exhibition opened the eyes of the world to the immense resources of India, and to the enormous requirements of the country previously unknown or neglected. And this success of the Calcutta Exhibition has awakened the enterprising community of the metropolis of Western India to the advantages of following suit. Exhibitions draw— attract a large number of people from far and near; holiday seekers and business men; *reis* and *ryot* and all classes are in attendance; and such a gathering can only be "good for local trade." This aspect of the immediate effect of an exhibition must not be forgotten while we subscribe to, and acknowledge, their wider scope and cosmopolitan advantages. The new Premier, Lord Salisbury, declared in a public speech delivered in connection with the opening of one of these undertakings in 1882, that—"It is due to efforts of members of the Royal Family in this country (meaning England) that exhibitions have been introduced as part of the commercial apparatus of the world, and no one who has watched the effects of the successive exhibitions that have been held, can doubt that they have powerfully stimulated the enterprise and intelligence with which the various branches of industry and commerce are conducted." The feeling is, however, that large International Exhibitions are too colossal for the busy people of to-day, with whom time is money. A confused panorama means seeing everything and learning nothing. Whereas, in this age of competition, the value of recurring changes in methods of manufacture, and the development of new trades and processes, can only be understood by "comparison." By restricting the field of observation, the mind is better enabled to grasp the industries represented, and to sift, weigh, and retain the information available regarding them. Hence technical exhibitions are advocated as the best means of training, instructing, and interesting manufacturers and merchant-buyers in particular domains. In technical exhibitions there is more

opportunity and greater facility for makers and users or producers and consumers to be brought into closer relation, which helps greatly in an interchange of ideas. This better enables one section of the community to meet the wants of another. The good-will engendered enlists sympathy, obtains encouragement, and commands success—even without the incentive of prizes and awards. For, in technical exhibitions, the scope of work is limited, there is more concentration of inquiry and observation brought to bear on the exhibits, which under the principle of "seeing and judging," would soon evolve the best by a process of consultation and comparison. Economy of production, advanced ideas, correct proportion, and good design could be easily detected by the experienced and interested without recourse to *practical* "testing," which may mean much or nothing at these shows—the honors of which are, we regret to say, very often acquired by special preparation, inducing abnormal conditions, which anticipate the best results. We have been unconsciously drifting into moral views relative to exhibitions which, perhaps, would be well left to the judgment of the reader. Whether general or technical, there can be no question as to the advantages of Exhibitions. Their good to the community at large is incalculable, and the possibilities in this respect might be exemplified by a single incident:—When the Swiss visited the exhibition at Philadelphia, and saw, to their astonishment, that the Americans were, in watchmaking and other mechanical productions, far in advance of themselves, they at once accounted for their own manufactures being at a discount in the American markets, and immediately turned their attention towards improvement, in order that they might not be behind their own specialties. This is one way in which an exhibition could operate in good effect. The best argument, however, of the benefits derived from exhibitions lies in the fact that they occur over and over again, and are still coming.

Miscellaneous Items.

TAKEN appears to be a demand for cattle and potatoes at Sumatra, and a Madras merchant has made a shipment of these from Negapatam, and similar consignments will shortly be made.

ANTHRAX having appeared among the horses of the K. D. Guards, it has been requested that Government Cattle should not be driven along the road from the Fort, leading through the Fort Lines, until further orders.

The Soldiers' Industrial Exhibition at Poona was opened on the 24th ultimo before a large gathering. There was a variety of exhibits, comprising articles of almost every description, which were so tastefully and attractively laid out as to draw the admiration of the visitors.

On the 25th ultimo was the great Hindoo holiday of coconut day at Poona when the monsoon is considered to be at an end, and coconuts are thrown into the sea to gain its favour. All the banks, Government offices, &c., was closed. In Bombay a large fair is held on the esplanade.

The pioneer efforts of Messrs Parry and Co., in the direction of expressing oil by steam at their factory at Cuddalore, have proved so successful that the firm are setting up two additional mills, one for pressing castor oil, and the second to meet contingencies such as breakage, accidents, &c.

The out-going traffic on the Madras Railway, from Mangalore, is very low just now, but an increase is observable in the import of goods, probably owing to the past very indifferent season, and the drought now threatening. Prices, too, are already rising, and altogether, prospects are anything but bright and encouraging.

The Government of India have, we learn, called for the records of the cases in which the two Judicial Commissioners of Oudh have differed in the construction of the law relating to the resumption of vested rights in that province. It may be hoped that this way will be found out of the unsatisfactory situation which was brought to notice in these columns on the 29th of July.

The Board of Revenue have issued a circular to the Collectors of all Districts except Cuddalore, directing them to forward a statement of the area to which each of the officers in the Revenue Department belongs, and the names of his relatives (any, employed in the same district) such a statement had already been received from Cuddalore during the vigorous regime of Mr. H. H. Farmer.

The steamer *Panama* has just arrived with a cargo of brick coal for the Administration and the machinery for the new oil press mills. The *Panama* met with very heavy weather in the late cyclone off Ceylon, and sustained damage to the extent of Rs. 20,000, and had to throw overboard some 50 tons of Government coal: the cargo generally, especially the machinery, was much damaged.

A MOVEMENT is on foot, the *Pioneer's* Bombay correspondent telegraphs, among the Exhibition guarantors to urge the Governor to abandon the project definitely. The Exhibition is now hardly likely to be a success. Its postponement in the first instance, and the doubts that have since been thrown over it, have affected its prospects irretrievably. And the guarantors very naturally desire to face the prospect of having to pay up their guarantee for the sake of an enterprise that would not bring credit to the city.

NEAR the village of Pusapatiraga, in the Virajapatnam district, a spring lately made its appearance, the waters of which were reported to possess great curative properties. News of the discovery spread rapidly, and natives for miles around flocked in numbers to the spot, with the view of being cured of the maladies under which they were suffering. A rough analysis of the water of the spring was made by the medical officer attached to the local dispensary, with the result that it was found to be highly charged with carbonic acid, and it is considered that it might consequently be beneficial in certain forms of disease. Some of the water has also been sent to the Chemical Examiner for further analysis.

Selections.

RULES TO BE OBSERVED DURING PREVALENCE OF SCARCITY.

OFFICIAL PAPER.

From C. S. BAILLY, Esq., C.S., Under-Secretary to the Government of India (Revenue and Agricultural Department—Famine)—To the SECRETARY to the Government of Madras, (dated Simla, 23rd June 1885, Circular No. 90-P.)

Now that arrangements have in almost every presidency and province been completed for the promulgation of a Famine Code, I am desirous to communicate to all local Governments and Administrations the character of the information which the Government of India is desirous of receiving in respect to any tracts in which there is, or is likely to be, any failure of harvest sufficient to give rise to serious apprehension.

2. The Government of India has not overlooked the provision in the Bombay and Madras Famine Codes of rules prescribing certain reports to the Government of India. To these rules, of which a copy is appended to this letter for easy reference, it has already accorded its approval in sanctioning the codes of the two presidencies. Some matters, however, with respect to which his Excellency in Council would be glad to receive information from affected tracts still remain, which are not sufficiently covered even by these codes, and I am therefore to communicate the following rules (in which the provisions of the Bombay and Madras Codes are as far as possible incorporated) for general observance. The essential difference between the instructions now issued and those contained in the Madras and Bombay Codes is that the latter provide only for a single report, whereas the former provide for periodical reports. But the modification which may be caused from time to time by change in prospects due to fall of rain, or increasing drought, &c., makes it necessary to provide for periodical reports during the continuance of scarcity.

3. In issuing these rules, the Government of India wishes it to be understood that it is constrained to consider itself ultimately responsible for the measures taken to meet famine or scarcity, and is at the same time obliged to keep itself acquainted with the financial prospects which any serious failure of harvest may involve. It is hoped that the Government of Madras will not find the instructions conveyed in the rules productive of material inconvenience. Any suggestions which can be made for their improvement will at once receive the consideration of his Excellency in Council.

ENCLOSURE No. 1.

Extract from the Bombay Famine Code.

2. The Governor in Council will, as soon as the approach of famine becomes definite, communicate to the Government of India all available information concerning it, stating the area which is likely to be affected, the economic condition of that area in

ordinary times, the number and class of persons likely to require relief, the crops affected and the extent to which they may be expected to fail, the contingencies on which the probable duration of distress depends, the position of the affected area as to local trade, food supply and communications, the arrangements proposed for famine relief administration and relief works, the extent to which suspension of land revenue may be necessary, the possible requirement of the services of officers from other provinces, and the financial position of the Local Government.

ENCLOSURE No. 2.

Extract from the Madras Famine Code.

When the season and rainfall returns received from the districts indicate the approach of scarcity, the Government will at once report the fact to the Government of India, and when the prospect of famine is imminent, they will further state the anticipated extent of failure of crops, the contingencies on which the probable duration of pressure depends, the area and population likely to be affected, the circumstances of the locality as to trade and communications, the probable numbers that may require relief, the general arrangements to be adopted, the relief works to be opened, the extent to which it is proposed to suspend revenue or to make advances, and what additional officers of different grades and departments may have to be called for from other provinces.

2. The Government at the same time will forward an estimate of the total expenditure likely to be required during the financial year, together with an application for a special grant of funds, when the Provincial and Local resources at their control are considered insufficient.

Rules to be observed in reporting to the Government of India the conditions of tracts suffering from failure of crops.

I. The first indications of failure of harvest or scarcity should be communicated to the Government by telegraphic reports.

II. When the indications are sufficiently serious to cause apprehension that, from continued want of rain or other cause, relief measures may have to be undertaken, the weekly reports should be supplemented by monthly written reports.

III. The reports should give as distinct information as possible regarding the areas affected (or likely to be affected) and should be accompanied by a sketch map on which such areas should be indicated by colours. A revised sketch map should be submitted whenever the area of scarcity expands.

IV. So soon as the information is available, there should be entered in one or more of the monthly reports—

(a) a list of the larger relief works which may, in case of need, be made available for each affected tract or district. If such relief work is one which would ordinarily require Imperial sanction, a separate report should be submitted for communication to the Public Works Department. A rough estimate should be given of the maximum number of people for which, in the event of scarcity becoming famine, relief might be required, and the number which will be provided for by the relief works, of which a list is given.

(b) an account of the economic condition of the tract in ordinary times, the crops affected and the extent to which they have suffered, the contingencies on which the probable duration of distress depends, and the position of the affected area as to local trade, food supply, and communications.

V. In the event of relief works or poor-houses being opened, or gratuitous relief being afforded, a summary of the numbers relieved by means of each agency during the month under report should be given. Information should also be given regarding the extent, if any, to which private charity and relief are being afforded.

VI. The rise or fall of prices should be specially noticed in every monthly report.

VII. When any material expenditure has been or seems likely to be incurred, the monthly report should give a brief statement of the amount spent or granted up to date, and an estimate of the available funds from which it is proposed to meet expenditure. If there is any reason to believe that the Provincial funds will prove insufficient to meet the exigencies of famine, the extent to which Imperial aid is likely to be demanded should be estimated.

VIII. The extent to which suspension of land revenue may be necessary should be stated whenever the adoption of such a measure is contemplated.

IX. In the case of serious famine being apprehended in a presidency or province, an estimate of the number of officers of different grades and departments likely to be indentured for from other provinces should be given.

X. When in any affected tract cause for anxiety is removed, a request that the tract may be removed from the list of affected areas should be included in the monthly report.

NOTE.—As a rule it will suffice to give information under IV (a) and IV (b) once for all, but whenever information is furnished under IV (b) heads, it should be distinctly stated that the information is afforded under IV (a) and IV (b), as the case may be. During the progress of events for better or for worse, the forecast originally given will doubtless be subject to occasional modification.

SUGAR-REFINING BY ELECTRICITY.

In the March *Sugar Cane*, page 116, we called attention to a Company which had just been started in New York for refining sugar by electricity; and we also gave a report, taken from a contemporary, of some sugars which had arrived in this country, and which, it was stated, had been refined by this process. We gave the account as a curiosity—no more believing it, than if we had been told that some one had arrived in Liverpool that morning having left New York the previous day in a balloon.

Experiments with this new process have continued to be made, with results, as reported, which are simply astounding.

Within the last few days we have seen Mr. Robertson, of Liverpool, who is interested in this company, and represents it in England. No one, we think, can converse with this gentleman without being persuaded that he most thoroughly believes in this invention, and that it really does what is reported of it.

He told us that a gentleman, residing in New York, in order to test the matter, had 3 cwt. of raw sugar taken to the inventor's room, for the purpose of being refined; he satisfied himself that there was no other sugar in the room except that which he had brought with him, and that there was no way by which the sugar could be replaced, except through the door, which he had securely fastened and sealed upon leaving. Within two hours he re-entered the room—during his absence the raw sugar had been passed through the machine by the inventor, and converted into refined sugar, the weight returned being within 1 per cent of the saccharine contents of the raw sugar.

An experiment upon a much larger scale has within the past three weeks been made under conditions set forth in Mr. Robertson's Circular, dated July 17, which we give at page 439, together with the report of the five gentlemen who were selected to certify to its genuineness; we notice that two out of the five gentlemen are the president and vice-president of the company. Assuming, as we do, that all is perfectly square, we think the company would have done better to have obtained the services of five well-known gentlemen who were perfectly disinterested.

The quantity of raw sugar to be refined was 80 bags—producing 40 barrels of refined sugar of "12 different sizes, from the finest granulated up to about the size of a small bird's egg" the time occupied in the process was seven hours. These gentlemen did not witness the operation itself, but they conclude their report as follows: "We have no reason whatever to doubt that the aforesaid refined sugar was produced by the said (Professor) Friend by his said process on the said 14th July from the aforesaid raw sugar."

The conclusion that one is driven to, with this information before us, is, that it is either a great fact, or it is a great fraud. The company are about starting some works to refine, by this process, 500 tons per day. We shall therefore know in a little while which of these conclusions is the correct one.

IF IT IS A FACT, it means that we are on the eve of a revolution in sugar refining, without a parallel in its history; it means that planters in all parts of the world can, if they choose, and have the capital, refine their own sugars on the spot. It opens up besides, a market for refined sugar with millions of people in India, who, from religious belief, are now debarred from its use on account of the animal charcoal employed in refining under the old system.

The particulars of the invention may be stated to be as follows:—

"The process is an electro-chemical one, which is worked by a machine, automatic in its action to a very great extent. Boiling and animal charcoal are entirely dispensed with. No syrups nor soft sugars of different grades are produced, the entire product being hard sugars in whatever forms or sizes which may be desirable to produce, that is, from finest powdered up to and including cut and pressed loaf. One valuable feature in this mode of manufacture is that all the saccharine matter in raw sugar, whether crystallisable or non-crystallisable, under the old system of boiling and filtering, is by this system rendered into hard sugar, with a small fraction of a loss—less than one per cent of the whole quantity. The cost of refining by this process is 2s. 4d. per ton (2d. per cwt.), and the time occupied not more than four hours."

By the favour of Mr. Robertson we have been furnished with samples of sugar refined by this process, and which are to our office, 37, Market-street, Manchester, for inspection.—*Sugar Cane*.

GERMAN BEET SUGAR CAMPAIGN, 1885-86.

[COMMUNICATED.]

Referring to the figures given to cane planters by Mr. Russell, of Demerara, in his pamphlet in the *Sugar Cane* for April last, "Reflections on the relative positions of Beet Sugar and Cane Sugar, as produced in the West Indies for refining in Germany and Demerara," it may be uninteresting to your readers to learn what the fabricants in Germany are doing for the 1885-86 crop. As an example I give some particulars of a factory—not a large one—which works up from 1,500 to 2,000 tons of beet sugar for refineries during the season.

The work in question belongs to the Peiner Sugar Manufacturing Company, which is under the management of the Technical Inspector, Mr. E. Riscke.

The Peiner Sugar Company have their work in the district of Hildesheim, where the large molasses refinery is making white sugar from molasses only. It is one of the oldest in that locality, and has worked nearly 20 years, showing dividends from 20 to 30 per cent.

Nearly all the roots worked are grown by the Company, and on a soil not at all favourable for beet culture. The factory has paid until now from 20s. to 25s. per ton of roots, which contain on the average 11.5 per cent of sugar. We learn from reliable sources that the Company have entered into agreements with the beet growers for the next crop to pay 70 pfs. per cwt., that is 14s. per ton of beet roots, real sugar beets, healthy, without dirt, the head or tops cut off, and not green-coloured roots, containing, according to the analysis of the chemist, not less than 11 per cent of sugar; the roots to be delivered at the works, and for every 100 tons of beet roots, the farmer or contractor has returned to him up to 35 tons of slices from the diffusion battery.

This well-pressed extracted beet is considered excellent food for the cattle, and, if well prepared, invaluable to the farmer. If, however, the farmer prefers a return in cash, which is not often, he is to receive 4s. per ton. The farmer is provided with the seed by the Company, and none other is permitted to be used.

If 85% beet sugar realizes more than 24s. per cwt. (net of internal tax, then the Company is to pay the farmer 10s. per ton for his roots, in the place of seed.

These are the general terms at the present time in Germany for 1885-86. The Peiner Sugar Company is one of those that agreed to give last campaign (1884-85) the full prices before mentioned, namely, 20s. to 25s. per ton, and have settled, without hesitation, with the farmers on this basis.—*Sugar Cane*

SUGAR-CANE AND SUGAR TRADE IN BRITISH BURMAH.

Memorandum by Mr. J. E. Bridges, Director of Agriculture, dated the 12th August 1885.

The cane-producing lands of British Burmah may be roughly divided into two tracts—

(a) The tract of shifting cane cultivation, in which the cane is consumed in the raw state;

(b) the tract of permanent cane cultivation, in which the cane is manufactured into Kyautaga* (gur).

2. The first tract may be taken to include all the lands on the seaboard within the region of tidal creeks, whereas the second tract consists of the lands situated in the interior of the province. Many districts will, therefore, belong to both tracts; thus in the southern part of the Hanthawaddy district, shifting cane cultivation is found in the circles of Lawadi and Sindapura, where as permanent cane cultivation is found along the railway line in Wanetohung, Talkhyi, and Okkan.

A.—TRACT OF SHIFTING CANE CULTIVATION.

3. It consists of patches of land cleared in the evergreen jungle which fringes the tidal creeks; the land is, as a rule, poor and will not yield a cane crop two years in succession, so that this kind of cane cultivation is never found in large continuous stretches of country, but only in isolated patches.

4. Area under cultivation.—The district returns give the area under cane as follows:—

	Acre.
Basseln	320
Thongwa	349
Hanthawaddy	111
Total	780

5. *Kind of cultivators.*—The cane-cultivators in this tract are, as a rule, Upper Burmans, who have immigrated into British Burmah, and who cultivate cane for two or three years in order to save enough money to buy cattle and cultivate paddy, or to be able to trade on a large scale. They generally combine petty trading with cane-planting and can hardly be called cultivators. The area of their plantations seldom exceeds one acre.

6. *Kind of cane.*—The kind of cane grown in this tract is called kyautaga or kyautahung. It is a large cane of light colour,

* Kyautaga is the Indian gur, only it is generally made in the shape of flat cakes instead of in oblong form.

with short, thick joints, and is so brittle that when passed through a mill it generally breaks off at the joints. It is usually eaten in the raw state, but is occasionally pressed in a hand mill and the juice sold. This cane is very juicy, but the juice contains but little saccharine matter. The cultivators never attempt to make kyautaga (gur) of it, and in describing an experiment made in Thongwa district, the District Officer says: "In this district the juice at its best only yields molasses. No amount of boiling will cause crystallization of sugar. The experiment had a fair trial in the Ma-abin jail; there not only the inferior but the best kinds also of canes were used, but the result was the same."

7. *Soil.*—The sites selected for cane cultivation are the muddy alluvium on the banks of tidal creeks, and they are chosen more with reference to the nature of the timber growing on the land and the facility of cutting it down than to the fertility of the soil. This soil is not generally suitable to sugarcane, but it is sufficiently fertile to grow one crop of the coarse cane cultivated, and cane is seldom or never planted two years in succession on the same patch of land.

8. *Mode of cultivation.*—The timber on the plot of land selected is cut down at the beginning of the dry weather and burnt in March. Vegetables, such as rice and Indian corn, are planted amongst the ashes and afterwards sold at a small profit. In September, after the land has been cleared of weeds, cane-pieces are planted in holes at a distance of two or three feet. These holes are in rows three or four feet apart; the cane-pieces are fastened down by a piece of bamboo lashing, to prevent them being washed away. In January and February loose soil is thrown up round the young plants, and in May and June supports are placed near each cane stool and canes tied to them with fastenings made of creepers. About August and September the canes are cut and sold in pieces.

9. *Irrigation.*—In some parts trenches are made to admit water during the dry season and drain the land during the rains. In other parts the plants are watered at spring tides by bamboo water-lifts; but as a rule, the water from the creek overflows the banks at high tides and no irrigation is necessary.

10. *Cost of cultivation.*—As a rule the cane plantation is cultivated by the owner with his family and no hired labour is employed. The following is an estimate of what the cost of cultivation per acre would amount to if only hired labour were employed:—

	Rs.	A.	P.
Clearing jungle	7	0	0
Price of plants at Rs. 6 per 1,000	12	6	0
Cost of planting at Rs. 2-8-0 per 1,000	7	8	0
Cost of supports at Rs. 8 per 1,000	9	0	0
Cost of creeper lashings at Rs. 5-0-0 per 1,000	9	0	0
Cost of labour for planting supports and binding the canes at Rs. 3 per 1,000	9	0	0
Total	60	0	0

11. *Yield per acre.*—The following table shows the yield according to experiments made by District Officers:—

	Area.	Number of canes.	Tons.	Cwt.
Basseln	0.29	4,904	11	9
Thongwa	1.00	16,980	28	14

The average yield per acre would, therefore, be about 17,000 canes.

12. *Price of produce.*—The canes sold at Rs. 20 per 1,000, so that an acre would give a return of Rs. 340.

13. *Estimated net profit.*—The net profit per acre would be Rs. 280, if the cost of cultivation alone is deducted. It would amount to Rs. 150 per acre if both the cost of cultivation (Rs. 60) and the cost of living (Rs. 130) of the family were deducted. It must be remembered, however, that these plantations are exposed to the attacks of rats and squirrels, and to the incursions of cattle, so that the full return is seldom obtained. It would, therefore, be safer not to estimate the net profit at more than Rs. 100 per acre.

14. *Condition of the cane cultivators.*—There is no information regarding the condition of cane cultivators as they change from year to year, and become gradually merged into the general body of cultivators or traders, when they accumulate enough money to cultivate paddy, or start as traders.

B.—TRACT OF PERMANENT CANE CULTIVATION.

15. The most important portion of this tract is situated in the valleys of the Bitta and Thabyu rivers (3,191 acres). The manufacture of cane into kyautaga (gur) is also in practice in other districts—Toungoo, Amberst, Kyauk Phyo, Sandoway; and within the last few years jaggery has been made on the railway line in the Hanthawaddy and Tharawaddy districts.* The land hitherto selected has been soil which receives annually alluvial deposits and can, therefore, be cultivated continuously without the use of manure. There can be no doubt, however, that a large area of land which does not receive any alluvial deposits could be cultivated either with the present cane or some other variety, but a rotation would then probably become necessary, and these lands are already occupied by Burmese or Karens, who show but little inclination to undertake cane cultivation.

* There are cane-crushing mills working at Wanetohung, Talkhyi, and Okkan in Hanthawaddy, and at Udo and Hrahsweyraw in Tharawaddy.

10. Area under cultivation.—The district returns of the area under cane cultivation as follows:—

Arakan	Akyah	82
	Kyauk Phyo	2,344
	Sandoway	1,044
Pegu	Prome	
	Tharrawaddy	
	Toungon	
	Shwegyin	
Toungay	Amherst	888
	Tavoy	110
	Mergui	138
Irrawaddy	Hanzada	
	Phayemyo	
Total		6,980

17. Races of cane.—The cane cultivators in this tract are generally Shan and Burman. The Burmans do not readily undertake cane cultivation, which requires constant attention and labour throughout the year and is, consequently, distasteful to them.

18. Kinds of cane.—*Madras or white cane.*—The Madras cane is said to have been brought to Bilin from Moulmein shortly after we occupied the country. It grows to a height of 11 feet and is so flexible that it requires no supports. It is the cane almost exclusively grown in Burmah for the purposes of kyanaga manufacture.

Kaungyan or elephant grass cane.—This cane is so called from its resemblance to the elephant grass. It is whitish in colour.

† The *myan* of Sandoway is probably the Madras cane, which is also known under the name of *myan*.

and grows to the same height as the Madras cane, but is much thinner. It is very flexible and does not require supports. It is indigenous to the Shan State and gives more juice (28 to 25) to each stool, but it is said to yield much less juice than the Madras cane.

Anagyan or Upper Burmah cane.—It is a reddish cane with short, thick joints.

Kyaukgahngyan.—It is a large cane of greenish colour, much resembling the Upper Burmah cane, and has short, thick joints. It is almost exclusively grown in the tidal creeks. It has been already described (paragraph 6).

Kyannet or black cane.—It is a thin cane of a dark purple colour with green leaves, and yields but little juice. Another variety is said to have purple leaves.

Kyannet or red cane.—This is a small, red cane with thin, hard stems. The Madras cane is the cane exclusively cultivated for manufacturing purposes, and the kyaukgahng cane is exclusively grown for selling in the raw state. The other varieties are but little grown, they are generally found on the outskirts of plantations, where they serve the same purpose as plantain trees to preserve plantations from the attacks of animals or the depredations of fire.

19. Soil.—The soil best suited to the cultivation of sugarcane in Burmah is that of the Bilin and Thebyu valleys. It is almost entirely grey loam mixed here and there with light clay. This land is covered during the rainy season by the river floods for a few days at a time, and a thick layer of alluvium deposited on it.

The soil on which cane is grown for manufacturing purposes in the other districts of the province is a generally deep rich loam. The cane-growing soils of the Shwegyin district have been analysed by the Chemical Examiner, Dr. Romanis, and the following is the result of the testings made:—

Analysis of Soils from Bilin.

	A	B	C	D	E	H	K	M
Soil of the cultivation most pointed out for cane-cultivation on the Bilin.	0.146	0.155	0.211	0.165	0.470	0.403	0.290	0.235
Soil taken from river opposite to where bank is lower and more flooded.	0.350	0.020	0.005	0.102	0.050	0.546	0.000	0.000
Soil of the northernmost point to which cane cultivation extends on the Bilin.	0.218	0.560	0.000	0.190	1.010	0.182	0.547	0.049

Dr. Romanis says:

"These soils are evidently produced by the decomposition of granite or some other primitive rock. In the sample of E, I found fragments of decomposing felspar, the constituent of granite that supplies potash to the soil. There is no doubt that this is the secret of the fertility of these soils. Another thing is that the soluble potash is higher than usual. They will yield several crops before they show signs of exhaustion."

20. Cane had been cut on the land from which selections were made, the juice tested, and the amount of kyanaga (gur) obtained had been ascertained with the following results:—

Name of soil.	Percentage of sugar in juice according to saccharometer.	Percentage of coarse sugar (gur) in juice according to experiment.
A	25.71	15.27
B	20.00	12.52
C	25.71	15.27
D	22.85	14.31
E	22.85	Not cultivated.
F	27.14	15.00
G	...	Not cultivated.

The percentage of juice was, however, taken from the different places at different times, and there was a month's interval between the testing of H and that of K. The cultivators themselves stated that the best kyanaga (gur) was produced by so: A and E, then by H, then D and K, and finally B. They stated that the kyanaga (gur) of B was bad owing to the land being flooded, and that the sugar of K would improve as the land was regularly cultivated year after year.

21. Comparing the result of the soil analyses with that of the testing of the juice and kyanaga (gur), Dr. Romanis remarks:

"The order of the productiveness seems to be that of the amount of phosphoric acid the soil contains. Leaving K out of account, as it was more mature when cut, it will be observed that the sugar obtained is very nearly proportional to the percentage of phosphoric acid. According to Villo, the phosphate of lime is the predominant constituent in sugar manure, but he gives no experiments to prove it. It is third in order of productiveness, and third in order of productiveness. The great amount of potash cannot be utilized by the plant for want of a sufficient proportion of phosphoric acid. K, according to the natives, comes after D, but D is a new land and, therefore, for a year or two, may yield good crops; but, if the analysis fairly represents its composition, it cannot last long."

"It is no doubt beginning to be exhausted of its soluble ingredients. What is extracted by hydrochloric acid does exactly correspond to what the plant can extract from the soil. I should say it was a fallow or change of crop."

"The soil should not deteriorate if nothing is removed from it but pure sugar, the constituents of which are entirely obtained from the air. If the crushed canes are restored to the land in any form, there is no loss, or very little, of mineral matter."

(To be continued.)

REPORT ON MINERALS IN TENASSERIM.

Iron and Manganese.—I received some specimens of iron ore from the Commissioner of Tenasserim. They had been sent in with an application for mining rights, and I was asked to report on their value. Analysis showed that the ore was free from sand and rock, but several specimens contained a large quantity of manganese—one as much as 45%. Since manganese is more valuable than iron, it was important to ascertain where were deposits of pure manganese in the neighbourhood.

I found that the specimens came from Yabagon, a few miles above Yembaling, a large village on the Salween, about 70 or 80 miles from Moulmein.

Yembaling is about two miles above the rope stations on the Salween, where the logs from the forests on the Upper Salween and Thaungyin are collected.

Above Yembaling the river flows through a gorge, where the current is interrupted by huge, rugged rocks, which must make the navigation impossible during the rains.

The iron stone deposit is seen on the east bank of the river for 300 yards northward from the waterfall at Yabagon. It was observed about two miles further up, on the west bank, exposed in a water course about 210 feet above the surface of the river, and again at Badattha on the west bank, near the flood-level of the river.

The rocks to the east of the river and in the river are composed of a poor limestone containing only 22 per cent of carbonate of lime and 78 per cent of sand. To the west the rocks are sandstones, ferruginous schists, &c. to the south-east again we have limestones containing 75 per cent of lime. The dip is 60° to the N.W.

The iron ore has evidently been deposited in a stratum of the limestone, and left a line of nodules lying along the outcrop by the weathering of the limestone.

These nodules are many of them hollow with crystals of oxide of iron lining the cavities; they frequently contain crystals of quartz and carbonate of lime.

Some nodules contain an appreciable quantity of manganese evolving chlorine gas when treated with hydrochloric acid, but not enough to be useful for making black powder. The majority of the specimens are excellent for iron.

The ore may easily enough be brought down to Moulmein in the dry weather, but the price of English iron is less than the cost of working and carrying it would be.

Thin films of a black substance are often found resting the rocks in the neighbourhood. This proves to be 'wad' or earthy manganese, in which Mr. J. T. O. White has found a trace of barium. It is probable that larger deposits may be found some day. I showed the people who guided us what to look for, and I hope we may hear of some discovery.

In the meantime manganese may be added to the list of minerals found in Burmah. The remark on page 13 of Mason's Burmah (Theobald's edition) should be expunged.

Analysis.

Black nodule from limestone, Yembaling:—

Peroxide of manganese	...	9.59
Peroxide of iron	...	11.74
Carbonate of lime	...	35.83
Sand	...	31.43
Water by difference	...	3.61
Total	...	100.00

contains traces of barium.

Manganese from Yabagon—	
Peroxide of manganese	50.83
Peroxide of iron	31.50
Peroxide of iron	7.20
Sand	3.25
Water	7.72
Total	100.00 gives 6.83 available oxygen.

Large rock, No. I—

Sand, &c.	77.25
Total	100.00

Limestone, No. II—

Carbonate of lime	89.13
Iron and magnesia, carbonates, &c.	31.87
Total	100.00

Kawkareik and Thaungyin Valley.

Kawkareik is 15 miles from Kyundo, a village on the Haung-thary where the launches from Moulmein stop. For some three or four miles from Kyundo, the soil is alluvial and occupied by rice cultivation. Then, to the neighbourhood of Kawkareik, we have undulating ground composed of a decayed metamorphic rock containing much iron covered with an open forest of trees. To the south and east of Kawkareik the country is level and under rice cultivation. The cultivators are principally Shans. To the N.W. the country is undulating and covered with forest, with tangya cultivation. The road to Myowadi runs along the channel of the Kawkareik stream—at this season a few inches deep. It is impassable for wheeled traffic. Goods are carried on elephants, or bullocks with paniers. I found it impossible to get a cart of the outbreak of elephant disease and cholera, which had entered the Karen from coming into the town. I therefore left my heavy baggage behind, and travelled with a caravan of bullocks carrying rice to Myowadi.

There seems to be a considerable trade done in this way in flinted bisulphide, shot and iron goods.

Two hours from Kawkareik the path leaves the valley and runs up a steep hill, running along the edge of a precipice. The principal trees are *Dipterocarpus* of various species, which attain a height of 150 feet. The undergrowth is composed of mass of bamboo and creepers of all sorts. The rocks are of various kinds, some metamorphic, micaceous, iron ore, &c. &c. and granitic rocks.

The next halting-place is at an old zayat (two hours' walk from Kawkareik, cattle require eight hours); after this the road is generally down hill, until we get clear of the mountains at Thungayin, 24 hours from the zayat. Here is a police station and a small settlement, with tangya cultivation on the banks of a small river, a tributary of the Thaungyin flowing north-east. The road leads almost due east to Myowadi through open forest; the soil is a decomposed ferruginous rock with bands of quartz. Near Myowadi the forest is replaced by bamboo, and traces of former vegetation in the form of briars scattered about are seen.

Myowadi now occupies about one-tenth of its former area as marked by the old walls. It is inhabited principally by Shans. The Thaungyin river is fordable everywhere in the dry weather, and does not form a natural boundary. The Dawna range seems to be the real division between the races. The Yabaling road here crosses the river from the south-east corner of the town.

There was much sickness in the place, and one of our bullock-drivers was seized with cholera. It was some time before I could get transport to the next halting-place, Dedangyi, better known as Shwe Ki's village, from a Karen chief who lives there. The road passes through a mixed forest. Near Dedangyi there are rice meadows belonging to Shwe Ki, said to be the only example of that kind of cultivation in the neighbourhood. There is also a large orchard filled with fruit trees and well kept.

The hills here are close to the river. They are composed of a very pure limestone, in some places passing into marble. Between the limestone and the river there are low hills of red clay. In the bed of the river the rocks are composed of a much decomposed granitic rock. Half-a-mile from the village, south-east, there is a section where a recent grave bed lies on metamorphic rock; above the gravel we have a red clay and laterite.

In the limestone I found marks resembling a Devonian coral, which occurs in the neighbourhood of Bristol, but the rocks have been much altered by igneous action, and the traces are faint. I found no minerals, but a piece of bituminous shale was brought to me, said to have been found in the river. It was waterworn, and could not have come far without being broken up in such a stream as the Thaungyin; but I did not find the stratum from which it came. It resembled in appearance the Lonsdale coal of Tenasserim.

About two hours from Dedangyi the river flows through a gorge between precipitous limestone rocks. The road is impassable for elephants, which here wade along the stream. The footpath runs along the riverside, then ascends and runs into a ravine; about 230 yards from the entrance the path enters the bed of a torrent, rising in the mountains beyond. This stream disappears into the ground through a circular hole between three and four feet in diameter. It no doubt enters the river below water-level.

After wading along the bed of the stream for about a quarter of a mile, we come to its source in a circular valley surrounded by steep limestone rocks called "Uya." This appears to have been a Karen stronghold. It was planted with fruit trees for the benefit of traveller by the father of the present Karen chief of the district. It is kept in order by two or three Karens, who live there and make thatch for houses. The garden is irrigated by the stream, which never dries up. The fruit trees were orange, lime, guava, jack, mayapple, mango, betel-nut, with plantains and pine-apples. The exit to the south-east is through a narrow ravine and down a dry torrent bed. The road runs through a mixed bamboo jungle and then through an open forest resembling the forest. The place of the tree is here taken by another species of *Dipterocarpus*. The soil is a red clay with fantastic blocks of limestone rising through it. The next halting-place is Koman, a large Karen village, lying at the foot of a range of limestone hills, which run parallel to the river. The low hills near the river are composed of granite and conglomerate. The open forest extends over these low hills as far as Panya. The jungle on the limestone is exceedingly dense; it is only in tangyas that there is a chance of examining the rocks closely. At Koman I found no fossils, but found pink and green shales in the limestone. This mineral often accompanies

metallic veins, but I found none here. The road runs along the riverside, and then over low hills with open forest until the Mekala river is passed; the road here divides. To the south-east it goes through alluvial forests to Panya, to the south-west it runs by the riverside to the village of Mekala. The limestone rocks disappear, and the gorge of the Mekala river is composed of metamorphic rocks like the Dawna range. At the entrance to this gorge I observed a conglomerate dipping 30° N. This is the only place where I found a good section of the strata. The rocks are generally indurated shales.

I here found a hot spring; the temperature was not over 120° F. It is about a mile from the meeting of the roads.

Towards Panya the road passes through alluvial plains covered with an open evergreen forest; it crosses the Ankaren and Ankraw streams and then the Gala, on which Panya stands. It is a small Karen village; the people are engaged principally in forest work. There are a few taungga gardens near.

Panya is the nearest village to Ankaren, where Mr. Fryer reported the existence of lead phosphate. The people could not ride me to the place, and had never heard of it. The country consists of low hills composed of red clay from the weathering of metamorphic rocks. The people said there was no limestone in the neighbourhood nearer than half-a-day's journey. The lead ore near Mr. Fryer, if it was near the junction of the Ankaren and Ankraw streams, must have been in metamorphic rocks above, and not in the limestone. There is little chance, mentioned in the search for the phosphates of lime as I hoped. I was therefore, of the opinion that the rapid rising of the river, due to the commencement of the rains. Although the primary object was not to find the first time. There remains the district has been observed in the Thungyin valley. There is a great deal of work to be done in the geological character of the country is nothing recorded of the Thungyin and Hlaingbwa. Also the between Shwegun or Yembalaw to have been geologically Haungtharaw valley does not appear over the mountains from examined. I returned to Kawkerik, a valley between Ledangyi. The road runs westward through a valley between limestone mountains, the lower part, covered with bamboo jungle, passing the sources of the Mekala and Thungyin streams. I followed the latter to Thungyinaung, where I crossed the mountains to Kawkerik. At first there are limestone rocks on both sides of the valley but going northward, we find sandstones and shaly cropping up, and the limestone forms the crests of the hills, the valley widens out, and there are rice fields cultivated by Shans; then the hills sink down into the undulating country between Myewadi and Thungyinaung. Thus we have a tract of limestone country south-east of Thungyinaung overlying the shales, schists, &c., which form the Dawna range and re-appear on the Mekala river.

From the mountains near Kemau we have a good view of Siam as far as Yahaing. The country appears a table-land, elevated about 300 feet above the Thungyin river, intersected with ravines and covered with forest resembling in forest. About 20 or 30 miles from the river is a range of mountains running north and south, parallel with the Dawna range. From the outline I judge it is of the same geological character. It appeared to be less impassable than the Dawna range, the mountains seeming to stand apart from one another.

Limestones, Thungyin Valley.

I.—Carbonate of lime	...	99.03

Dondami.

The existence of lead and copper ore near Duzinzeik on the Dondami river has been reported. The place is about five miles from the station of the Duzinzeik and Thaton railway. A precipitous limestone rock rises out of the river on the left bank.

The traces of copper turned out to be green stains produced by a species of conifer.

The rock is a very beautiful white marble and well adapted to architectural purposes. It has been proposed to use the Ataran limestone for some ecclesiastical buildings, but I do not think it can surpass the Dondami marble in colour or in the accessibility of its situation.

THAT HUSBAND OF MINE

Is three times the man he was before he began using "Wells Health Renewer." Druggists.

A. W. Mason & Co., Calcutta, Sole Agents.

Nodules of a hard stone occur here and there on the surface of the marble. These were analysed and found to be almost pure silica. They resembled chalk flints. Some were hollow, the cavity inside being filled up with limestone. The variation in the composition of the limestone from Yembalaw southwards shows it to have been deposited in a gradually deepening sea. At Yembalaw we have clay and sand mixed with the carbonate of lime; further south clay without the sand, as in the dark blue limestones of the Salween valley. Then at Dondami we have the pure carbonate, with nodules of silica representing silicious sponges living on a still sea bottom.

BOOKS ABOUT THE DAIRY.*

MANY well-educated people know next to nothing about the manufacture of cheese, and very little about that of butter; but they need no longer be ignorant on either subject, as the two books under notice will supply them with all the information that can well be learned by reading about the dairy. The big book is well worth reading both to those who keep cows and to those who consume their produce; but readers who master the contents of even the little book will know a great deal about the matter. Both works are equally readable; and, as the smaller is a sort of condensation of the larger, this is much to say in its favour, for concentrated literature is usually of the driest description.

Mr. James Long starts with the theory that, "although both corn and beef are often, very often, grown at a loss, yet milk, cheese, and butter almost always fetch remunerative prices"; and he seems to think that dairy farming is the key to profitable agriculture. In comparing the number of cows kept in Great Britain and Ireland with those of other countries, he finds that we have only 1 cow to 12 cultivated acres, whereas in Germany there is 1 to 7, in Sweden 1 to 6, in Belgium 1 to 7 or 8, in Holland 1 to 5, and in Norway 1 to 4, while even in France, the

proportion of cows to cultivated acres is about equal to our own. The author, having developed in this country, it has been calculated that our annual production of milk is worth forty-seven millions sterling; yet we import about as much butter as we produce, and four-fifths as much cheese. It is unsatisfactory to reflect that of the milk consumed throughout the country, 22 per cent is adulterated, and that little more can be said for the butter. In a Report of the Local Government Board, it is stated that Londoners alone pay "between 70,000l. and 80,000l. a year for water sold under the name of milk." Yet the percentage of adulteration is said to be higher in Salford than in London. At the same time it will be a comfort to many to know that their milk is adulterated with water, and as a rule, water only. While on the subject of the poverty of the milk sold in towns, we may observe that it is as often owing to quality of the food given to the cows as to the use of the pump. Grains and distillery wash are largely used by dairymen who supply towns and cities, for it is well known that such food makes cows produce a very great quantity of milk, and of a proportionately poor consistency. Adulterated butter must on no account be confounded with the substance known as butterine. That food is manufactured in various countries both in Europe and America, but the greater part of that which is used in England comes from Holland. Butterines and margarines consist of the refined fat of beef mixed with skim milk, the former, when prepared for use, being known under the name of oleo. It is the fine internal fat of the steer, and after being washed, ground, and thoroughly melted in large cauldrons, it is wrapped in clean white cloths, and placed in a press where a hydraulic force of many tons is brought to bear upon it, when a yellow oil, much like olive oil in appearance and consistency, exudes and runs off into tanks of hot water. This oil is still refined and further purified, and finally it is allowed to "solidify, when it is packed in casks and stored." At one large manufactory in the Netherlands as much as 50 tons of this oleo are weekly to 12,000 gallons of milk. In this particular case the butterine is improved by the addition of twelve tons of real butter, which give a "grain" to the artificial production.

An industry which has increased greatly of late is that of condensing milk. To reduce milk to about one-sixth of its bulk, and to put it in a condition in which it will keep for a length of time, is

CALCUTTA:—SATURDAY, SEPTEMBER 12, 1885.

[No 37]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING THE 2ND SEPTEMBER 1885]

General Remarks.—Very slight rain has fallen in the Madras Presidency during the past week. In Bellary rain is urgently wanted, and prospects are reported to be very discouraging. In Madras, Coimbatore, and Salem prospects are also unfavourable. It is also wanted in Kurnool, Ganjam, Kistna, and Tanjore for the standing crop. In Mysore the situation remains unimproved, as little or no rain has fallen during the week under report. Generally speaking, prospect is fair in the hill tracts, but unfavourable in the plains and it is believed that, if rain does not fall within the next fortnight, there will be a great loss of the dry crops of the province. In Coorg the season continues favourable.

In Bombay rain has fallen recently, but it is wanted in several talukas. In the Deccan and Southern Mahratta country, crops are withering in parts of Poona, Ahmednuggur, Sholapur, Dhawar, and Bijapur, and food for a scarce in parts of several districts. In the Betwa and Hyderabad more rain is wanted for the standing crop. In the Central Provinces wet weather (rains), and a break is much wanted in the northern districts. Crop prospects are favourable. Rain has been almost general in the Punjab, and the harvest prospects continue good. In the North Western Provinces and Oudh rain has fallen in most districts, causing injury to crops on low lands. General prospects are good, but a break would be very beneficial. General rain has fallen in all districts in Bengal during the week, but in places in the Rajshahy division and Behar more is wanted. Excessive rain and floods have caused considerable damage, particularly to the rice and crops in the Burdwan and Presidency divisions and the khadar crops in Behar and Chota Nagpore have also been injured to some extent. The rice harvest is progressing, and the transplanting of aman is nearly completed. In Assam the weather is reasonable and prospects generally good. In British Burmah, longline and transplanting have been nearly completed.

Cholera continues to be prevalent in the Madras and Bombay Presidencies, in Raipore in the Central Provinces, and in some districts of the North-Western Provinces. Elsewhere the public health is generally fair, and prices are fairly steady, except in Bengal, where the price of rice continues high, and in Mysore, where prices show a slight tendency to rise.

Madras.—General prospects fair, improved in Anantapur, in Bellary very discouraging, in Madras, Coimbatore, and Salem reported to be unfavourable.

Bombay.—Rain in most districts, more wanted in several talukas of the Deccan and Southern Mahratta country districts. Crops withering in parts of Poona, Ahmednuggur, Sholapur, Dhawar, and Bijapur, and damaged by excessive rain in parts of Shurab and by insects and blight in parts of Kurrachee and Hyderabad, fodder scarce in parts of Nasik, Ahmednuggur, Sholapur, Khandesh, Bijapur and Bilgaum. Cholera general, fever and cattle-diseases in parts of same, and small pox in parts of two districts.

Bengal.—General rain has fallen in all districts during the week, more rain is wanted in places in the Rajshahy division and Behar. In parts of the Burdwan and Presidency divisions excessive rain and floods have caused considerable damage particularly to the rice and crops, for the same reason the khadar crops in Behar and Chota Nagpore have been injured to some extent, elsewhere the agricultural prospects are satisfactory, the rice harvest is progressing, and the transplanting of aman is nearly completed. Price of rice continues high throughout the province. General health is good, but fever is appearing in some districts.

A. W. P. and Oudh.—Heavy rain has fallen in most districts, causing injury to crops on low lands and to houses in Farrukhabad. General prospects are good, and would be better for a break. Markets well supplied. Prices steady. Cholera continues in some places, has

abated in some, and has broken out in others; general health, of men and cattle is good.

Prajab.—Rainfall almost general. Health and harvest prospects good. Prices generally stationary.

Central Provinces.—The weather has been very wet in the northern districts, and a drier weather is much wanted. There has also been heavy rain in Chhittagurh, elsewhere the weather has been fine, with occasional showers, and has been very suitable for cotton and millets.

British Burmah.—Slight cholera in Chittagurh; small-pox slight in one district, elsewhere public health good, cattle disease severe in one district. In the other districts, elsewhere health of cattle good. Poultry and transplanting nearly completed. Rains seasonable.

Assam.—Rain good, rice suffering from want of rain in some parts of the district. Harvest of *dhawal* and *marak* crops finished. Transplanting of all crops continues. Common rice 15 acres per acre. Weather is too dry for the health good.

Mysore.—In the district of Channarayana, rain since last report. Dry crops in critical condition. No present appearance of rain falling soon. Pasture and water reported to be failing. Cattle in poor condition. Public health fair, only 2 cases of cholera reported during week. Prices show a slight tendency to rise. Generally speaking, prospects are fair in the hill tracts but unfavourable in the plains, the common opinion is that if rain does not fall within the next fortnight there will be a great loss amongst all the dry crops of the province.

Bihar and Hydrabad.—More rain needed to prevent standing crops being damaged. Cholera still prevalent in the city and suburbs but general health in the district is good. Prices—wheat 14, white musk 14, coarse rice 12, yellow rice 22, and tur 15 per current acares rupees.

Central India States.—Total rainfall 44 1/2. Flood at Rowah on night of the 24th inst., after fall of 12 1/2, considerable damage to houses property but no loss of life. Cholera still reported from several districts of Rowah, otherwise health good. Prospects fair. Break much needed.

Rajputana.—Cauks full, wells filling. Crops and health good, Indian corn and wheat in particularly damaged. Prices stationary. Weather fine, apparent break in monsoon.

Nepal.—Health and prospects good. A few cases of cholera only.

Letters to the Editor.

OUR JUTE INDUSTRY.

TO THE EDITOR,

SIR,—The state of our Jute industry, as revealed in most of the published balance sheets during the past eighteen months, is very far from being creditable. One would think in looking over these documents, that the great end of a Jute Mill was not to make money, but to lose it as fast as possible. But then of course it is other people's money, and that makes a difference. What can be the reason for the continuation of so lamentable a policy? Is it for the purpose of supplying coolies with work? Or from a benevolent desire to supply bags steadily under cost price? Or is it simply that the Managing Agents may go on receiving a handsome commission, as long as the poor goods are able to hold out under the killing process? One thing is certain, were these Mills personally owned by those more immediately responsible for their management, they would not go on falling away as at present, with a palpable loss staring them in the face, of from ten to fifteen thousand rupees a month, exclusive of tax and wear of machinery.

A Jute Mill Association was recently formed from which great things were expected, but it was speedily found that on one point—and that the most vital for the moment—the Mills would not “associate,” viz., the curtailment of production. Each therefore did that which was right in its own eyes. Some, such as Sowrah and Budge-Budge, boldly shut their doors; others, such as Champdany and Wellington, cut off one third of their production, while the greater number rattle away, shuffling out their rupees by the thousand, and the supine shareholder stands looking on, as dumb as the sheep before her shearer. I understand that although the members of the Association failed to bring about the one step which would have cured the present distress, they still meet once a week, and amuse themselves by passing harmless resolutions, fixing the minimum prices of bags, and separating with the charitable hope, if not belief, that all will be loyal to those prices until they rise again. Any attempt to galvanise prices, while production keeps ahead of demand, is an idle dream. The weekly meeting itself is a good thing, as it will enable the office *chakr* who manage the Jute Mills, to compare what they call their “ideas” together, and will leave them less at the mercy of the story which the broker tells concerning the rate which a neighbour is willing to accept, rather than lose the order. But the next time they resolve to fix the minimum prices of bags, I would recommend them at the same time to pass an order fixing the minimum height of low water at Kidderpore and they will find that the *Meoghly* will be as obedient to their wishes, as the Jute trade will be, under present conditions. The agents of the Steamship Companies met the other day in solemn conclave, and ordered freights to go up five shillings. Freight smiled when he heard the order, and putting his finger to his nose in a metaphorical manner, promptly went down half a crown. So much for the nostrums with which our modern mercantile Canutes would seek to stem the present tide of trade depression.

For the present sickly condition of the Jute trade—unless the disease is to be allowed to cure itself by the elimination of the weaker mills—I confidently affirm that there is no remedy of a feasible kind possible, except the curtailment of production within the limits of demand. Were this policy adopted at the bidding of the shareholders (it is useless to expect managing agents to do it of their own free will), then matters would speedily right themselves at both ends; the price of raw material would go down, the prices of bags would go up, and profits would be made. Will the shareholders move?

While speaking on the subject of curtailment of production, I venture to hazard the opinion that even in ordinary times, the Jute mills are run far too many hours per week. They work during all the daylight there is, from Monday morning till Saturday evening. The consequence is that it is simply impossible to keep the machinery in the state of cleanliness and repair that ought to be its normal condition for effective work. In such circumstances rapid deterioration sets in, and there are some mills at the present time whose machinery is in such a deplorable state, that as a matter of fair market valuation, it is not worth much more than 50 per cent of what it stands at, in the book account. These long hours, too, are unfair to the European assistants at the mills. If the machinery has to work six days, the majority of these assistants have to work for seven, as Sunday is the only time for cleaning and repairing. Need it be wondered at then, that many of these men break down under the exhausting nature of their work? I am firmly convinced, and I believe the more experienced of the working managers of the Jute Mills would agree with me, that these long hours are a mistake even from a profit-and-loss point of view. I make bold to affirm that if the Jute Mills had wrought only 60 hours per week, which is 4 hours more than they do at home, giving suitable meal hours during the day and stopping altogether on the Saturday afternoon for general cleaning and overhauling of machinery, not only would as much money have been made, but the mill properties themselves would have been in infinitely better condition, and more easily kept in proper order than they can possibly be at present. Thirty per cent of the workers could have been dispensed with, and the European supervision would have been much more effective. The majority of the Europeans connected with the mills would hail with delight the advent of a 60 hours' Factory Act for India, and we do not believe the shareholders would have any cause to regret its introduction. But for present salvation, I earnestly hope that common sense will assert itself, and production be lessened until demand overtakes it.

A. B.

Editorial Notes.

The latest reports from the two districts in Assam and Cachar are generally favourable, although cold nights are beginning to be complained of both in Jorehaut and the Darrjeeling districts.

**

The value of the gold imports during the first four months of the current financial year was Rs. 1,37,47,713, and of that exported Rs. 10,14,503; whilst the value of silver imported was Rs. 4,85,14,457, and of that exported Rs. 20,32,910. This leaves a balance of both metals in favour of imports of Rs. 5,02,14,765.

**

The assay value of coins and bullion received in the Indian mints in the months of April, May, June, and July last, was Rs. 4,76,81,500, and of that coined and examined Rs. 4,92,80,931. Of this latter amount Rs. 1,81,70,706 was coined at the Calcutta Mint, and Rs. 3,11,10,225 at the Mint in Bombay.

**

The salt market during the first quarter of the year 1885-86 showed considerable dulness as compared with the corresponding quarter of last year. The quantity of salt of all descriptions cleared this year was 21,29,121 maunds, against 24,78,324 maunds, and the net amount of duty levied was Rs. 41,03,558 against Rs. 47,90,905.

The exports of Tea from China and Japan to Great Britain, from the commencement of the season to the 13th of August, amounted to 84,953,534 lbs., as compared with 76,473,962 lbs. in the corresponding period of last year. The quantity exported to the United States and Canada during the same period was 25,200,148 lbs. as against 31,142,214 lbs.

**

The summer session of the Royal Agricultural College at Cirencester having come to a close, the diplomas, medals, scholarships, certificates and other distinctions won by the successful students were distributed by the Principal. Among the winners of distinctions, we note the names of Baboo Byomkesh Chakravarti, M.A. (Bengal Government scholar), and Pestonji Rastooji Mehta (Indian student), who have carried off diplomas. Honorable mention is made of Messrs. Mookerjee, Banerjee, and Khasheras, all Indian students.

**

In a despatch dated June 23rd, the Secretary of State for India acknowledges the receipt of the letter of the Government of India in the Revenue and Agricultural Department, dated 12th May last, recommending the continuance, for a term of two years, from 15th August, of the appointment held by Mr. Mills, of Cattle Disease Inspector, Madras Presidency, and Veterinary Lecturer for the Agricultural School at Saidpet. He says he is prepared to sanction this arrangement, and to assign to the post in question a consolidated salary of Rs. 800 per mensem, subject to any modifications which may hereafter be necessary on the organization of a Civil Veterinary Department.

**

We understand that, at a meeting of the Orissa People's Association recently held at Cuttack, it was resolved to address the Commissioner of the Division, on the subject of holding an Agricultural Exhibition at Cuttack during the ensuing cold season. A similar movement has been set on foot at Chintrasah. These are hopeful signs that the people are becoming alive to the importance of introducing improved methods of agriculture into their lands. It should be the duty of the Government to encourage and foster this feeling; and to place every facility within the reach of associations, and other corporate bodies, which have taken the initiative in a matter of such importance. They should not only be encouraged, but helped and supported in their efforts.

According to the quarterly return of the Registrar-General, the population of the United Kingdom in the middle of 1885 was estimated at 30,325,115 persons; that of England and Wales at 27,499,041, of Scotland at 2,907,736, and of Ireland at 4,918,338. In the United Kingdom the births of 285,612 children, and the deaths of 176,256 persons were registered in the three months ending 30th June. The natural increase of population was therefore 109,356. The registered number of persons married in the quarter ending 31st March 1885 was 105,464. The birth-rate in the United Kingdom in the second quarter of 1885 was 31.5 and the death-rate 19.5 per 1,000. The marriage-rate in the first quarter of this year was 11.8 per 1,000.

A contemporary refers to a "valuable invention" in the following terms:—The present yield of gold in the world is about £20,000,000 sterling yearly. It is computed that there must be at least 100,000,000 of tons of tailings on the different gold-fields of Australia that have had only a portion of the gold taken out. Mr. Henry Moon, late of the Mysore Gold Field, announces that after years of experiments and practical working, he has produced a machine that can, without attention, and at a cost of not over 1s. a ton, save 90 per cent of the gold in different ores, and practically the whole when the gold is free. It is to be hoped that this is true. Australian and Californian gold-seekers acknowledge that they fail to extract much more than half the gold contained in some of the gold ores.

We understand from a home contemporary that the prospectus of the Fibre and Planting Company of South India is now in circulation, and subscriptions are invited to a share capital of £20,000. The directors are Mr. C. E. Collyer, Colonel F. Henderson, and Messrs. A. R. Hindu and Mackenzie. The chief object of the company is to be the growth of tea, but this will be supplemented with that of tea, pepper, rubber, tobacco, and cocoa. A provisional contract has been made for the purchase from Messrs. A. R. Hindu and Co., of the Cannoth Estate, situated about twenty-one miles from Tellicherry. It consists of over 900 acres, including thirty-five acres on which successful experiments of the above products have been conducted. The purchase consideration is £4,000, of which £2,500 is payable in cash, and £1,500 in fully paid shares. It is calculated by the directors that they will leave a net profit of at least £5 to £7 per acre.

The harvest statistics of 1885, issued by Mons. B. Estienne, on the crops of the world, are given below. One hundred is taken as representing an average, and the figures for the corresponding period of previous years are also given for comparison:—

Years.	Wheat.	Barley.	Oats.	Potatoes.	Beans.	Peas.	Rice.	Grass Hay.	Clover Hay.
1881	90.0	110.0	85.0	98.0	100.0	100.0	80.0	85.0	65.0
1882	92.2	95.4	105.1	100.4	103.1	101.0	107.1	112.6	118.4
1883	91.8	94.0	106.0	120.6	98.7	117.8	102.4	96.1	108.4
1884	112.2	98.1	94.3	138.4	88.2	91.4	78.8	79.1	82.4
1885	101.4	99.2	99.5	92.7	84.7	81.8	30.6	98.1	100.4

The blue-book recently issued, containing the report of the Registrar General for Ireland, contains useful information regarding Irish agricultural statistics. It appears that the area of land in Ireland under crops in 1884, compared with 1883, exhibits a decrease of 63,957 acres, 91,660 acres being in tillage, while there is an increase of 30,703 acres in meadow, and clover. There is an increase of 761 acres under woods and plantations, and of 151,429 acres under grass. There is a decrease of 1,182 acres under fallow, and 9,050 under bog, waste, water, &c. The crops in 1884, compared with the previous year, show a total decrease in cereals of 79,079 acres, wheat having decreased by 26,850 acres, oats by 33,469, and barley by 18,760 acres. In green crops there is a total decrease of 8,870 acres, potatoes having decreased by 7,615 acres.

It is said that, owing to the competition of Chinese and Italian silk, the manufacture of mulberry silk in the Poona division continues to decline, but on the other hand the demand for tussar silk is steadily increasing. The output of this silk in the Poona division last year was valued at Rs. 96,030, as against Rs. 40,675 in the previous year. The higher classes of native are said to prefer the country-made cloth, owing to its being more durable than that of Manchester, but the poorer classes, with their usual improvidence, nearly all buy the latter, owing to its being somewhat cheaper. The consequence has been that many hereditary weavers have abandoned their calling, and taken to other work. Still some qualities of country cloth hold their own in the market, and it is estimated that at the Howrah Mill, the chief mart for the cotton goods of Hooghly, Howrah, Midnapore, and parts of Naddea, the sales of this cloth amount to 18 lakhs of rupees a year.

A local contemporary publishes a paragraph, stating that on the 28th March 1882, when an artesian well at Bahour, in French territory, was being bored for, a bed of lignite was met with, which was followed to a depth of 500 metres in the following fortnight. After the necessary investigations had been made, and the required authority obtained, Monsieur Francois Deloncle commenced regular boring operations in the vicinity with encouraging results. Having completed all necessary preliminary arrangements, he proceeded to Paris, and has formed there a J. S. Brock Company for working the mines. He expects to return to Pondicherry this month, and to commence active operations in October. Estimates and workings drawings for shaftings, buildings, roads, &c., are in readiness for an immediate prosecution of the work, and several superior and subordinate officials have been engaged, and are on the spot, or at Pondicherry. The promoters of the company have proved by three separate analyses the value of the material found at Bahour and its suitability for steam purposes.

The Bhagulpore correspondent of the *Statesman*, writing under date the 2nd instant, says:—

I am glad to tell you that Mr. S. Sakhatat Hossein, the Agricultural Officer for this division, is making great progress in his work. I hear he has constructed a number of silos in different parts of the division, and has introduced the improved "duplex" plough in two or three places. I understand that the manager of the Bareilly estate is about to start a "Demonstration Farm," identical to the Doonraon one in all respects except in size: the Doonraon farm is 10 acres in area, and this farm will be one of 100 acres.—Another young zemindar, Baboo Gout Chundra Roy, has agreed to place a plot of 40 bighas of land under the management of Mr. Hossein, to be cultivated according to the improved method.

It is gratifying to receive such testimony to the efforts being made by officers of the Bengal Agricultural Department to diffuse agricultural knowledge among the people. Mr. S. Hossein is going the right way to work, and there is little doubt that he will succeed in doing much good in the district to which he has been posted. We have not yet heard what Mr. A. C. Sen is doing. It would be for the public good if the Director of Agriculture were to publish a monthly summary of the work done by the several officers under him.

It has been decided to undertake the compilation of a "Special Manual of the Wynaad," and Mr. A. E. C. Stuart, Special Assistant Collector, Nilgiris and Malabar, has been entrusted with the task, for which abundant material has been got together. On this point, Mr. Stuart, in his report to Government, says:—"The materials for a manual of the Wynaad are rapidly increasing, and a vast number of original documents, which have probably never before been brought to the notice of Government, have been collected since the institution of the jannam inquiry. These documents comprise old records, both in English and Malabar, unclassified from among the archives of various public offices, and numerous entries, topographical plates, and writings on bamboo in Malayalam produced by various claimants. The principal facts relating to the amsams

which the janmam inquiry has been completed have been set forth in the various reports, &c., already submitted, and the whole are being gradually collected and arranged with a view to their ultimate publication in accordance with the instructions of the permanent Director of Revenue Settlement and Agriculture. That a compilation of the kind under reference is necessary, is evident from the fact that the district "Manual of the Nilgiris," written by Mr. Grigg, does not treat of Nilgiri-Wynaad, which was only constituted an integral part of the Nilgiri district in 1877. The district "Manual of Malabar" is still unpublished; and as south-east Wynaad no longer forms part of the Malabar district, that tract will not fall within the scope of the Malabar manual.

It may be safely predicted that a manual of the Wynaad will be of much interest, for to quote Mr. Stuart:—"The Wynaad takes an exceptional tract not only from its geographical position and past history (which has yet to be written, and the full materials for which are only now being collected, and which will doubtless be largely added to in the course of the janmam inquiry and new revenue settlement), but is important as containing the most valuable teak forests in India, and as being the seat of the principal planting operations in the presidency. Immense amount of capital has been sunk, not only in coffee, cinchona, and other special products (notably cardamoms, pepper and, very recently, fibres), but in gold-mining speculations which, however, have not yet been successful. The materials therefore for a special 'Manual of the Wynaad' which would form, as it were, a connecting link between the manuals of the Nilgiri and Malabar districts, are abundant; and if the final results of the janmam inquiry and revenue settlement were embodied in some such collection of facts, which would also contain an epitome of the principal facts of historical, political, scientific, and commercial importance, which must otherwise remain scattered in various official reports, &c., the work would, I believe, serve (to some extent at least) the interests of public utility." We are glad to see that the task of compilation has been allotted to Mr. Stuart, who is an officer of much promise, and one who takes a real interest in his work.

It has been decided by Government to distribute prizes, aggregating Rs. 19,750, at the several horse-shows and fairs to be held in Northern India during the present financial year. We note the following among the principal places on the list where fairs and shows are to be held, and the amount to be expended at each place:—

Batesar, Rs. 600; Jalahad, Rs. 700; Allgurb, Rs. 1,000; Boolundshuhur, Rs. 1,250; Saharupore, Rs. 1,000; Dehra Ghazi Khan, Rs. 2,000; Morarigurh, Rs. 1,000; Mooltan, Rs. 2,000; Jhang, Rs. 750; Navchandi (Meerut), Rs. 1,500; Gujrat, Rs. 1,200; Shahpore, Rs. 1,000; Lahore, Rs. 1,000; Rawul Pindae, Rs. 2,000; Hyderabad, Rs. 600; and Umritsar, Rs. 500.

It appears to us that it would have been more expedient (and would certainly have attracted better specimens of cattle), to have held a smaller number of fairs but of larger pretensions, and to have given larger sums of money in prizes. There is no doubt that the system of offering prizes has had good results; but it seems a pity that money should be simply frittered away in giving insignificant prizes for indifferent specimens of live-stock, when the offer of more substantial prizes, by holding out better inducements to breeders and exhibitors, would have resulted in the exhibition of better specimens.

Forestry says that "the sunflower artichoke is being extensively cultivated in Belgium, as by a new process of distillation some 8 per cent of alcohol can be obtained from its tubers. More than 3,500 acres of poor, almost waste land, around Antwerp will this year be covered with the plant. The residue after distillation is nutritious. France has thus also in the way of cultivating large stretches of her poor, thin, chalky, and schistose soils with this new crop. The cultivation of Jerusalem artichoke is very much the same as that for potatoes. February or March is the time to plant; the earlier, the better.

will be the yield. Indeed if the soil be sufficiently friable, the planting may be made even in water. Owing to the quantity of its foliage, the Jerusalem artichoke draws a great deal of its food from the atmosphere. Artichokes are now being cultivated alike in Iowa and Arizona as a material for fencing park. In field culture they are not hard to eradicate, and must be replanted at least once in two years. An Iowa farmer finds one or two acres sufficient for quite a large herd of hogs." In India this really nutritious vegetable is so common, and so easily cultivated, that it is surprising why it is not more extensively grown.

The full returns of the indigo crop for last year show to have amounted to 1,66,507 maunds, of which 19,668 maunds came from Bengal, 62,038 maunds from Behar, 35,141 maunds from Benares, and 59,660 maunds from the Doab. Upwards of 68,000 maunds from these two latter districts were of native production. The brokers estimate the Bengal crop for next season at 19,800 maunds, which is only a trifle more than last year. Manufacture from the first cuttings has been finished in Behar, and the result is estimated to be about 41,000 maunds, which is more favourable than was at one time anticipated. Khoontee Mahal is now commencing in most parts of Behar, though some factories will not begin for another week. Heavy rain in the absence of sun has done a good deal of damage to the koontee crop, which is still very backward in many parts, and, owing to the lateness of the season, is not likely to yield as much as last year. The accounts from Benares and the Doab are still unfavourable, as more heavy rain has fallen, and it is estimated that the output from these districts will not exceed 55,000 maunds, which is much less than last season.

It is very necessary that owners and breeders of cattle and horses should be able to ascertain, by the pulse, whether their animals are in health or otherwise; upon this subject, we take the following hints from the *Nation & Live Stock Journal*:—

The healthy pulse in the adult horse is from 36 to 40 beats in the minute, in the ox from 45 to 50, in the sheep from 70 to 80, and in the pig about the same as the sheep. In young animals the pulsations are faster, and in old ones they are slower than those in their prime. In very young ones they are of course, very much faster. The healthy pulsations may also vary in the same class of animals according to breed, temperament, or even individual peculiarities, and a very slight cause, such as a sharp word or a "start" may increase the beats in an excitable horse 10 or 15 beats per minute. The frequency of the pulsations may be taken anywhere that an artery can be felt, by light pressure on it with the finger, or the beatings of the heart may be felt on the left side, just back of the elbow. But were our knowledge as to the state of the pulse to be limited merely to the frequency of the beats, it would be small indeed. The tone, volume, and force, have also to be taken into consideration. A very frequent pulse often indicates great weakness. The pulse in the horse, ox, and in most of the lower animals, is most conveniently felt at the angle of the under jaw, where the submaxillary artery coming from the inside, passes under the lower edge of the jaw-bone, and mounts up towards the face, just in front of the large flat muscle that closes the jaws. The frequency of the pulsations varies so much in different animals, according to the disease, its stage, its severity, etc., that a detailed statement as to its beats would be too long and would be of little service to the reader. We will merely say that few horses will survive long, with a continuous pulse of 100. A continuous pulse of 60 to 65 in abdominal disease, lingering colic, etc., would indicate danger, and a pulse of 80 to 70 is not uncommon in favorable cases of influenza, or other lingering or debilitating diseases of the organs of respiration of the horse.

The following is a summary of Messrs. Wm. Jas. & Hy. Thompson's fortnightly circular of Indian Tea, dated London, 13th August, 1885:—"The auctions during the fortnight have comprised 22,000 packages, including 3,900 from Ceylon and 300 packages of reprinted and second-hand tea. The porters have shown a general disposition to realise rapidly, and with this in view some have resorted to sales without reserve. An improvement has taken place in the tone of the

market, but competition has not been strong enough to do more than harden prices. The trade, however, holds reduced stocks, and as soon as larger supplies of good qualities come forward, business is likely to be very brisk, judging from the prices paid for some fine Assam teas in to-day's sale. (Quotations for low and medium grades are now fully on a par with prices at the same time last season; but the rates recently obtainable for teas classed as 'fine' have been disappointing to exporters; and it is evident that the probable effect of low stocks has been over-estimated, and that insufficient allowance was made for the power of the dealers to keep out of the market when it suits them to do so. The latest samples sent from most parts of Assam give promise of a really good crop, and a general improvement is noticeable in numbers from Darjeeling and adjacent districts. In Cachar and Sylhet growths, there is much variation, and only a few invoices giving complete satisfaction have so far been seen. The shipments from 1st May to 31st July were 9½ million lbs., compared with 7½ million lbs. to same date last season. At last week's sale in Calcutta about 12,000 packages were offered: prices are reported to have declined, the average obtained being 9½ annas against 9½ annas and 10½ annas at the sales of 30th and 23rd July. Ceylon Teas maintain their character and sell readily, the average price standing at 1s. 3d. per lb. The new Kisoows having arrived, it is possible to form a fair estimate of the China crop and of its influence upon the value of the Indian. Opinions differ about the Kisoows, but the general impression is that they are barely of average quality, while the Monings are distinctly inferior. The supplies will, therefore, be mostly of low grade, and the effect upon Indian, broadly speaking, will be to keep down the price of inferior teas of all makes, and to enlarge the demand for fine liquoring qualities, irrespective of leaf. The shipments from China are heavier than they were last season, and the visible supply of Tea is only from 9 to 10 million lbs. less than last year, although on 1st August the stock was 20 million lbs. lighter. The deliveries were again small in July, but the daily duty payments are beginning to increase somewhat, a sign that the trade is coming to the end of the surplus stocks cleared in the spring. The exports to the Continent, &c.—which mainly affect the China market—were below last season.

We have before us the results of the trials made with the Manila plantain hemp and the wild plantain stalks by the Glenrock Company, Pundich. As might have been expected, the experiment has virtually proved a financial failure. Our readers may judge for themselves by a perusal of the following extracts, which we quote from the papers placed at our disposal. Mr. Minchin, the manager of the Glenrock Company, in his report, says:

A trial in the treatment of Manila plantain hemp was made here in the Death and Killwood machines, belonging to the Company, on 31st January last. Mr. Guard sent from Captain Cox's Nalken Shola estate well grown Manila plantain stems obtained from Manila hemp stock received from Mr. Ballard, Collector of Malabar, in 1863-64, and since growing on that estate. One hundred and seventy-nine large stems were delivered at the mill, which weighed 10,073 lbs., or about 60 lbs. each stem, and after passing these through the Death and Killwood machines, there was produced 159 lbs. of clean fibre, say 1.49 per cent of the green stuff. The cost of treating this fibre, drying, sorting, and preparing for market, was Rs. 4-3-0, or at the rate of Rs. 63 8 0 per ton of clean fibre, valued in London at £28 per ton at present depressed rates. There is 90 per cent of water in the green plantain stalks; of the remaining dry vegetable matter, we saved 15 per cent of good fibre.

In the Philippine Islands the cost of preparing the fibre is estimated at one-half the value realized on the coast, and the people employed at this work are paid accordingly, an expert being able to prepare about 12 lbs. of fibre per day; and the average produce is one pound of fibre from each stem sold at average 100 pounds in weight.

Wild plantain stalks have also been treated here at the Company's mill; some being sent to England with the Manila plantain fibre from Nalken Shola estate for valuation and comparison. The stalks of the wild plantain are not so large and

well grown as those of the Manila plantain, very few attaining to 50 lbs. in weight; but there seemed little difference in the texture or appearance of the two fibres.

I had the Rhea fibre most worthy of consideration, and hope to have 50 acres under this cultivation shortly.

The Acting Director of Revenue Settlement and Agriculture Madras, in reviewing the result, says:—

The account of the experiment, though interesting, contains no details of the number of the plants sown on an acre of ground, or of the number of cuttings which can annually be made, or of the cost of carriage of the raw material from the place where it was grown to that where it was prepared, or of the charges connected with the carriage, &c., of the fibre to England.

The valuation of the Manila fibre is given at not more than £10 per ton, say Rs. 12½. The cost of treating, drying, sorting, and preparing it for the market was, at the place of manufacture alone, Rs. 61 8 0 per ton, or rather more than 1/2 of the value of the fibre in the English market. When other charges come to be deducted, there would be, if any margin of profit, but a very small one indeed.

Although the stems used for the experiments were evidently of considerable age, the plantations from which they were obtained having been put down so far back as 1861-4, the pattern of fibre, as compared with the standard, was not quite 1/2 per cent, and this is described by the experts who examined it as containing a very considerable proportion of exceedingly indifferent stuff, as poor as the under the price per ton of the whole far below that mentioned by Mr. Minchin. The wild plantain fibre was still worse.

It seems clear that unless much improvement, both in the method and cost of preparation of this fibre, can be made, cultivation of it cannot possibly be made remunerative.

A copy of the report of Messrs. Collyer and Co. on the fibres transmitted to them by the Glenrock Company is enclosed.

The following reports by Messrs. Collyer and Co. speak for themselves:—

Wild Plantain.—Very mixed and irregular, mostly very weak, a strong portion fairly strong, a good deal being flaggy refuse, with scarcely any fibre in it. When the fibre is fairly strong, it is fairly well cleaned, but apparently a good deal is intrinsically too poor to bear cleaning efficiently. The proportion of stronger fibre may be too small to be worth separating, otherwise it would appear desirable to ship that portion only in future, and then it might realize £15 per ton and upwards, mixed as it is. The bulk is too poor for use alone, and for mixing purposes, it will only realize very low prices, say £7 or £8 per ton.

Manila Plantain from Captain Cox's Nalken Shola Estate.—A somewhat similar fibre to above, with a larger proportion of strong, a small part being good, useful, clear fibre of good color, somewhat approaching ordinary Manila hemp; but the great bulk is poor, weak, flaggy stuff; the same remarks as to cleaning apply. Where the fibre is sufficiently bold and strong, result is satisfactory; on the whole, unless the stronger fibre can be kept separate, the price must be very low, say about £10 per ton; the best alone should be worth £25 upwards.

ENSILAGE vs GREEN FODDER.

II.

We have been unable to take up this subject earlier, owing to other pressing matters requiring attention. In our last article under this heading, we expressed our conviction that ensiled fodder, when properly prepared, was superior to fodder in its green state, so far as its nutritive qualities were concerned. In support of our view, we quoted the testimony of General Wilkinson, as bearing most directly upon the question under discussion, which arose out of our dissent from the views expressed by Mr. D. T. Allen, of the Bengal Agricultural Department, as to the value of ensilage. Mr. Allen addressed a letter to us which appeared in our issue of 22nd ultimo, in which he questioned the accuracy of the results obtained by General Wilkinson, alleging as his reason that no weights were given by the General, not the quantities of grass and ensilage upon which the cows were fed; and to further strengthen his argument, he quoted a letter, dated 28th May 1885, addressed by that gallant officer to the Government (which we regret we have not seen), in which he is said to have

written as follows :—" With this universal (but variable) daily decrease of yield, it has been found impossible to tabulate the advantage gained by the use of ensilage, for increasing the yield of milk." In fact, that General Wilkinson himself had some doubts about the accuracy of his own statements !

Now, without going any further, we have again glanced over General Wilkinson's report ; and we can hardly believe that he deliberately mis-stated facts in order to demonstrate the superiority of silage over green grass. In all ages, innovations and inventions have had supporters and opponents ; but when it is taken into consideration that the system of ensilage is, and was at the time General Wilkinson reported the result of his trial, in the experimental stage, it can hardly be said that he was carried away by his enthusiasm for the new system to give such a colouring to his results as to actually misrepresent facts and figures. Admitting for a moment that he omitted to note certain minor points, which Mr. Allen thinks entirely vitiate these experiments, the main fact remains unaltered, viz., that certain cows fed respectively on silaged and green fodder, showed an increase of yield and in richness of milk when fed on the former. We are not disposed to discredit General Wilkinson's statements. Should the lines be read by him, he will no doubt take an early opportunity of setting us right.

With regard to the opinions of scientific gentlemen in Europe and America on the value of ensilage, it may be well to make a few prefatory remarks before venturing on the subject. In India it seems to have been generally understood that any sort of receptacle will serve the purposes of a silo. Nothing could be more erroneous. We are favoured, from time to time, with reports of experiments in ensilaging fodder in various parts of the country. They are, without exception, not of much value, and we have frequently had occasion to point out the bald and worthless character of these reports. The results of such experiments prove *nothing*. They are wanting in every item of detail upon which a correct and reliable opinion could be formed. Not one of the so-called experiments have fulfilled the necessary conditions. The *idea* seems to have been misunderstood, and there is an amount of ignorance prevalent as to the nature of ensilage, that positively staggers us. As an instance, we may mention that unused limekilns, old 'blind' *kutcha* wells, and the like have been used as silos, from which satisfactory results have actually been expected ! As a rule, experiments have been conducted in a most perfunctory manner, without any regard to details, no care being taken to note the temperature, or other important items necessary to demonstrate the value or otherwise of the system. It appears to have been thought sufficient to state the size, cost and nature of the silos used, the weight and variety of fodder silaged, and whether cattle ate it freely or not on the silos being opened. On one occasion the writer (Deputy Commissioner, Amherst District) in his report, said : " I find that two silos were made in October 1884," and then proceeded with the stereotyped description on hearsay evidence, not having actually seen the silos. We have digressed from the subject-matter of this paper, but we have done so to point out how impossible it is to arrive at a strictly accurate estimate of the relative value of silage and green fodder in this country under the present slipshod methods of conducting such experiments.

To return to the point. The evidence taken by the Royal Ensilage Commission is conflicting. Some scientific men maintained the superiority of ensilage over ordinary fodder, while others were of a different opinion. It would be tedious to quote at length, but by following the evidence closely, we find that the consensus of opinion is on the side of silage. Professor Sheldon, in a paper on "Sweet Ensilage," published in the *North British Agriculturist*, and in which he reviews Mr. Fry's valuable work on this subject, writes as follows :—

Many would-be reformers are carried off their feet by enthusiasm that is wanting more or less in discretion ; but this is not the case with Mr. Fry, who may be regarded as the original pioneer in the domain of sweet ensilage in this country, and his book is the rolled-down result of much study and experiment. Mr. Fry regards the question as beset with difficulties, which can only be met by intelligent attention to details, which are constantly varying, and he declares he has ' neither seen nor heard of a silo which perfectly fulfils the necessary conditions ' ; he also declares that even

if such a silo were in existence, it would not be ' possible to ensure results always good alike.' This is, of course, obvious when we reflect that the result depends on the quality of the grass or other raw material used for the purpose, on the amount of moisture it contains, on the degree of maturity at which it has arrived when it is cut, on the peculiarities of its growth and structure, on the weather at the time, and on other conditions which provide plenty of scope for the exercise of ability and judgment.

The foregoing passage needs no comment. Further on, the Professor says :

Mr. Fry is more cautious than some writers have been on this topic, when he says that the silo does not render the ensiler absolutely independent of weather and other circumstances ; and in giving this timely warning to farmers who may haply have been carried away by what they have read elsewhere, he is not only doing the best service to ensilage as a system, but is lessening the volume and risk of oral disappointment. At the same time, the difficulties spoken of may be overcome by careful and intelligent attention, and success is within reach of every man who will take the necessary pains. These points are definitely laid down, viz. (1) A perfect silo must be air-tight, water-tight, and ' heat-tight.' (2) The forage put into the silo must not contain more than 75 per cent of moisture. (3) The temperature of the silage must rise above 122 Fahr., or it will be sour. These points are clear enough, but they require the exercise of care and judgment. To a man whose mind has seized the principles of the system, there is no more difficulty, all things considered, than in hay-making ; but even in hay making, we see a great deal of non-success, which is the result not of bad weather only, but also of carelessness and ignorance on the part of farmers, in so apparently simple a process.

The necessary requirements of a proper silo are, according to Professor Sheldon, as follows :—

A silo must have even and perpendicular sides, in order that the weighted covering may follow the silage closely as it sinks. The form of it, however, may be round, instead of square or oblong, but in any case the inner surface must be smooth, straight, and perpendicular. Stone or brick walls are plastered with cement ; concrete walls, may, perhaps, be made to do without a plastering of cement, and in this event they are probably the best walls that can be used for a silo. It is obvious that the walls, whatever material they may be built of, must be strong enough to resist any pressure that may come against them from the inside ; this pressure, however, is not very considerable. There is no need for a ' drain or other outlet for moisture at the bottom ' of the silo. If a doorway is left in the wall for convenience of emptying the silo, it should be made perfectly air-tight before the silage is put in. This may be done without much difficulty, providing the door is well made and strong, the framework properly constructed and the packing even and sufficient. Perhaps the best way is to break up the doorway when the silo is empty, plastering it inside with cement, like the rest of the inner surface of the silo. The roof of the silo must be high enough above the square to admit of having the ensilage trodden evenly around by the walls and close up to them.

It will thus be seen that it is not every hole dug in the ground that will answer the purposes of a silo. The Professor winds up his paper in the following terms :—

The temperature at from 4 to 6 feet from the surface should reach at least 122° Fahr. in two or three days after filling. Even if it reach 140 to 160° so much the better ; if it do not reach the desired height, this may be regarded as proof either that the stuff is too wet or that the filling and compression have been going on too quickly. As there is no fear that spontaneous combustion will ensue, the temperature may be ascertained closely enough by the aid of an iron rod, simply thrusting it down into the mass and trying its heat by hand when it is withdrawn. Ordinary British crops do not need chaffing for a silo, but they should be evenly spread in it, and well trodden down, specially near the walls.

Our author, who has produced a valuable book, advises farmers to try ensilage at first on a small scale, until they have learnt to make it properly ; then they may extend the system as much or as little as they think proper. The crops, earliest should be of good quality, and in a proper state of maturity, for the ensilage, excellent, placid herbage will produce silage of a quality unsuited for the production of good milk. The system of ensilage adds one more resource to the farmer, but it is not calculated to supersede either hay-making or root-growing in any very marked degree. It is obvious that while hay must contain only some 15

percent of moisture, and silage may contain 75 per cent, the crop preserved is more easily digestible in the one case than in the other, and silage may be made when hay would be spoiled by the weather. It is easy enough to make good hay in fine weather, and silage can be made when it would hardly be considered fine, though, as it would seem, wet weather is suitable for neither process, though less so for hay-making than for ensilage.

In the *North British Agriculturist* of 22nd July 1885, we find the following remark :—

An experiment with ensilage against hay and roots shows that five cows, receiving ensilage only, consumed 349lbs. per day, at a cost of 5s. per week. The same number consumed 400lbs. of roots and 5lbs. of hay daily, at a cost of 7s. 9d. per week. In thirty-seven weeks a balance of £25 8s. 9d. appeared in favour of ensilage, and the quality of the milk was good.

Turning now to America, we find the following in a leading article in a recent number of the *Farmers' Review*, one of the most ably conducted agricultural journals we have seen :—

It is claimed that fermentation is desirable for the reason that all green food taken into the stomach of the animal shortly becomes sour, and that the souring in the silo is really the first stage of digestion, but performed before it enters the stomach of the animal, instead of after its introduction; certain it is that animals feed upon this sour silage with a relish, and it has proved a most valuable food whether for milk, beef, or simply a sustaining ration, as the testimony of hundreds of intelligent farmers in this country, Great Britain, and on the continent of Europe proves. Under this system of producing sour silage, the method has been to fill the silo as rapidly as possible, usually cutting the material fine with a cutting machine, tramping as closely as possible while filling, covering with boards and weighting at the rate of from 100 to 200 pounds per square foot with stones, boxes of sand, or other heavy material; or applying an equivalent pressure by lever or screw force. Within the last two years a new theory of ensilage has been developed, which promises, as we think, to supersede the old theory and practice. It is this: that the germs of fermentation are destroyed by a heat of 122° degrees Fahr. And that these once being destroyed and the air excluded, no further fermentation or change will take place in the mass, and the result is sweet instead of sour silage. To develop the requisite degree of heat to destroy the germs of fermentation, slow filling in place of rapid filling is adopted. Two or three feet in depth is filled in, spread evenly over the bottom and allowed to heat up till the requisite temperature (above 122° degrees) is developed, when another layer is put on and left to heat up, and so on, until the silo is full, or the material all in. The heating of each layer destroys the germs of fermentation in it. The addition of the next layer excludes the air from it, so that no more germs can be added to it, and the temperature gradually subsides. As each addition becomes heated up, the fibrous material becomes softened, and each addition made above acts as a weight to closely compress it, so that when the filling is completed, at the end of two weeks or more, it has become so solidly compressed that but little weight is needed on the top.

It is the first process of digestion which takes place in a silo; hence the superiority of silage over fodder in a green state. It loses but an infinitesimal portion of its solid feeding qualities by this change. But it follows that good, wholesome food, which can be easily digested and assimilated, must be superior to food not possessing this quality, notwithstanding that the latter may contain somewhat more solid feeding-matter. It is the chemical change that takes place in a silo that enhances the value of silage.

We agree with Mr. Allen that the superiority of ensilage has not yet been entirely proved. As we have said, the system is yet in its experimental stage, and it will be years before it can be so proved. The broad fact, however, remains that, in the great majority of cases the experiments with ensilage (when properly conducted) have demonstrated its superiority over ordinary green fodder.

With reference to the concluding words of Mr. Allen's letter of 10th August, "that as long as certain butchers and dairymen in England object to receive the produce of cattle fed on ensilage," we note he has omitted to state that it was only in the case of cattle fed on garbage and vegetable refuse of the most abominable kind which had been ensiled, and of which "certain dairymen and butchers came to hear," that they refused to accept "produce of cattle fed on ensilage."

MUNICIPAL FARMS.

We have been favoured with a mass of correspondence between the Government of Bengal and the Municipal Commissioners of Howrah, on the question of the disposal of the night-soil of the Municipality. We cannot possibly publish the correspondence, but the letter, dated the 30th June, from Mr. Forbes Mitchell, Municipal Commissioner, to the Chairman of the Municipality on the subject of a Municipal Farm, seems to us to be valuable. We can make but a few extracts from the remainder of the correspondence. We note then that the Magistrate of Howrah, in a letter to the Commissioner of the Bardwan division, alluding to a former report from Mr. Forbes Mitchell, on the Bantra night-soil trenching ground or depot, writes as follows :—

The inspection report of Mr. W. Forbes Mitchell is especially valuable, and brings clearly to light the real causes of the difficulty. The depot, if the trenching ground deserves the name, is much too small for existing requirements, and the result is that the conservancy department of the Municipality is forced, for want of space, to return to used-up land, and to re-open old trenches much too soon. Mr. Mitchell notes this fact very emphatically.

The authorities thus clearly see that the whole difficulty as to the disposal of night-soil arises from the want of space, and unless the Government is prepared to assist the poorer municipalities by grants or loans, the present system of wasteful and dangerous nuisances, misnamed night-soil depots, or municipal trenching grounds, must continue. We see from the annual report of the Municipality of Howrah, that the municipal authorities have to provide for the disposal of 60 tons of night-soil daily, which, by the present system, is not only wasted, but converted into an offensive and dangerous nuisance. Now Mr. Forbes Mitchell's scheme means that one ton of this night-soil manure is ample for manuring 30 square yards of land per annum to grow the most exhausting class of crops. The whole quantity would therefore suffice for richly manuring a farm of 650,000 square yards, or 136 acres of land per annum. A successful Municipal farm means both health and wealth to the Municipality; but to initiate it, a large outlay is required, much larger than the Municipal income can afford, and unless the Government comes forward with funds, either as a grant or a loan, the scheme must fall through, and the people of Howrah and Seebore continue exposed to disease and death in their midst, from causes such as are described in the following extract from a letter by Mr. O'Donnell, the Magistrate of Howrah :—

I observed that the trenches in process of being charged with night-soil were shallow for the purpose, and far too much filled with it. The fecal matter was poured in a semi-fluid state into the trenches, to the depth of six to eight inches, and then reached to within the same distance from the surface of the ground. It seems to me that no soil could absorb and assimilate such a quantity of excreted matter except in a period measured by years. The shallowness of the trenches in use was explained on my viewing the trenches just being re-opened for the reception of night-soil a few days hence. I found Mr. Forbes Mitchell's strictures on their condition more than established. The trenching men told me they could not dig deep or stand in the trenches whilst digging, on account of the underlying abomination which one of the men showed me was still soft and unabsorbed by the surrounding earth. The smell from these trenches was very bad, and after months of decomposition, the gases rising from their contents must be noxious in a very high degree. How far the influence of these odours reaches, I cannot say, nor what effect they have on public health round. I am fearful of using language which might be hereafter described as exaggerated, but I must say that I cannot imagine, and have never experienced a more noxious stench arising from fecal matter.

We have here an official description of what exists at our doors, and we beg our readers to note that it is not the Municipal Commissioners, who are responsible for this condition of things but the Government of Bengal, under whose administration it was established, and who are morally bound to find the funds for reform. Reverting to Mr. Forbes Mitchell's scheme for a Municipal farm, about 550 to 600 acres of land would be required, which the Municipality would have to

acquire under the "Land Acquisition Act." For properly and profitably working such a farm, it would be necessary to lay it out in a regular system of fields separated by accommodating roads, either semi-pucca for the light cart traffic on the farm, or by the system of light tramways, and each field thoroughly fenced with barbed steel wire fences, which are light, strong, and durable, and do not occupy too much ground. After laying out each fence and road, the whole ought to be lined with fruit trees of superior quality, mango, lichee, guava, jack, coconut, &c. &c., with plots of the best plantains—all of which would be most remunerative, and require but little cultivation after the first cost, and if the plants were carefully propagated by an intelligent *mull*, even the first cost would be small. This scheme of Municipal farms will, we hope, command the attention of Government and of the Municipal authorities.

The Banra people have certainly been very long-suffering and patient under a condition of things almost incredible, when we remember that it has existed within sight of Calcutta. The Lieutenant-Governor deserves our acknowledgment for the response made by him to the remonstrances which have appeared in the public newspapers upon the subject, but Mr. Ware Edgar might, we think, have assumed a different tone towards the Municipality from that which pervades the final paragraph of the letter of 8th June, to the Commissioner of Burdwan on the subject. It is admitted that the defect which has so long marked the administration of the township has been that of the Government itself, and that the Municipality simply inherits the present condition of things from its civilian predecessors. Surely, then, the tone which characterises the following paragraph might have been somewhat different:—

The Lieutenant-Governor is aware that the present Municipal Commissioners of Howrah are not entirely responsible for the objectionable state of things at Banra. Its origin dates from a period anterior to the present condition of the Municipality. It rests with them, however, to remedy the evil; and appeals to Government are useless, &c. &c.

The Municipality is in no way answerable for a state of things which prevails all over Bengal, and would have prevailed till doomsday, but for the resolution of the Supreme Government, that its intensely centralized system of rule shall give place to the government of the people by themselves. It is not the Howrah township alone that wants the very elements of Municipal administration. It is the same everywhere, and will remain the same while the Government attempts the impossible task it has set itself, and the curtailment of which it is so disposed to resist. It will be time enough to speak of the responsibilities of the nascent municipalities of the province, ten years hence, when they have been fairly put upon their trial, and failed. One would really imagine from the tone in which the Government addresses these new-born institutions, that they were loaded with the sins of years, and had grown hoary in neglect and iniquity. What we see all over Bengal to-day, is a total and almost incredible want of local rule of any kind, through the determination of the Government to engross all powers in its own hands. In pointing out to the people the very task that lies before them of making up for past neglect, we might have expected that the Government which is chargeable with this neglect, would have expressed some generous regret at the nature of the inheritance they are bequeathing the people. The attitude of the Secretariat reminds us of that of the dying spendthrift who, having wasted his son's estate, calls him to his bedside, only to reproach him with the fact that he has made its redemption nearly hopeless, and dies with a malediction on his lips, for the broken fortunes and wasted estate to which it is his misfortune to be heir.

MODELS OF INDIAN AGRICULTURAL IMPLEMENTS AT THE LONDON EXHIBITION.

The following Circular Memorandum, dated 15th May 1885, has been issued by the Government of India, Revenue and Agricultural Department, to all Local Governments and Administrations:—

The Agricultural Court of the London Exhibition should contain a set of typical agricultural implements and machines or models thereof from each province.

After correspondence with the Directors of the Agricultural Departments in all provinces, it has been determined that models of large machines should be constructed of the full size, and that small implements should be shown full size. The decision whether in individual cases the former or the latter scale should be employed, is left to the discretion of the provincial authorities, subject to the suggestion that all hand implements, such as bill-hooks, saws, &c., should be sent full size.

The main object of the collection is that English manufacturers should be made aware of the character of agricultural machines and implements used in India. For this purpose it is not necessary that specimens of every kind of implement or machine used in each province should be shown. This is especially the case where large and heavy implements, such as ploughs, harrows, and the like, are concerned, of which one model of the kind of plough, harrow, &c., most commonly used is thought to be sufficient. Varieties may be described by diagram or letter press.

It is more desirable that a complete set of small implements, such as saws, small and large, or tools commonly used by carpenters and blacksmiths for cutting wood and other work, which requires the tool to have a strong steel edge, should be sent to the Exhibition, as it is not unlikely that English manufacturers will succeed best in finding a market for this class of implements. Care should at any rate be taken not to omit any implement of the kind which is largely used in any part of the province. It is suggested also that an implement which has been in use will be preferred to a new one made for exhibition.

The collection should be accompanied by a list, of which 500 copies may be printed. In order to ensure some uniformity, a specimen form is appended, the general size and arrangement of which should be followed. The type used is somewhat large, as it may be found convenient in some cases to paste cuttings from the list on the specimens, and should therefore be easily read.

It has been suggested that each implement, machine, or model should have firmly attached to it by wire a label such as is used by gardeners on which the name of the province and the number on the list, the name of the implement, and a statement that the model is of full or $\frac{1}{2}$ size, should be written in indelible ink. As it is intended that the collection should remain permanently in London after the close of the Exhibition, it is necessary that measures be taken to prevent any chance of the identity of the exhibit being lost. The label should, therefore, if the above plan is followed, contain the information given in columns 2, 3 and 4 of the form as in the sample appended,* and should bear

*PUNJAB List of Implements and Machines.

No.	NAME OF MACHINE OR IMPLEMENT		Use for which used.	Whether extensively used in what Districts and by what class of people.	Particulars as to Manufacture.*	Local Price.
	Ver-nacular.	English.				
1	2	3	4	5	6	7
1	Damr or Dech.	Bill-hook.	Lepping branches and cutting down brush wood.	Extensively used by the villagers of the Western Himalayas.	Made by every village blacksmith in the hills; of native iron, not of steel, seldom with steel edges, and the hard wood of the handle.	Rs. 2 0 to 3 0

* NOTE.—If possible, place of manufacture, character of wood or metal usually employed, and where materials are usually obtained.

Label suggested.

PUNJAB.			Full size.
1.	Damr or Dech.	Bill-hook.	Used for lepping branches and cutting down brush wood.

conspicuously the name of the province from which the implement is forwarded. The question as to the best form of permanent label will be subsequently decided, and further instructions on this point may be therefore awaited.

As the collections are intended to be of permanent advantage to the Agricultural Department, it is hoped that funds may be provided for them from provincial sources. It is impossible to allot any portion of the Bombay loan grant for the purpose, and the limited funds at the disposal of this department will make it difficult to provide any sufficient sum for the preparation of anything like a complete collection. All charges for carriage will, however, be paid by the Imperial Government. Early information is requested whether sufficient funds will be forthcoming for the purpose.

In addition to a set of purely agricultural machines and models, it is proposed to supply models of some of the machines used in trades connected with agriculture, such as oil presses, silk winders, cotton looms, &c. Funds for this purpose will be supplied by the Government of India.

A list of the latter class of machines of which it may be suggested that models should be constructed, should be forwarded to the Exhibition office at Calcutta at a very early date with a rough estimate of cost. The models should ordinarily be one-fourth of the full size. In some cases it will be desirable to have clay or wooden figures of the labourers or cattle employed to work the machines. But questions of this kind will be determined in direct correspondence with the Exhibition Branch of the Revenue and Agricultural Department, which is immediately responsible for the preparation of the collection referred to in this paragraph; although it is hoped that every reasonable assistance will be given in the matter by the provincial authorities.

If the officer to whom this circular is addressed is not the officer in charge of the Agricultural Department of the province, it is suggested that he should place himself in communication with that officer for such instructions or advice as may be required in connection with these collections.

Miscellaneous Items.

THE Mysore Excise Department is busy collecting information regarding the local manufacture of beer, with the view of bringing the said manufacture under the same supervision and regulations as attack.

A CORRESPONDENT, writing from the province of Shansi, says the increase in the cultivation of opium this year is very striking. The former Governor of the province, Chan Chih-tang, vigorously repressed the growth of opium, crowding it back into secluded fields, but this year the farmers make no attempt at concealment, and the poppy flourishes apace.

MORE walls have reached Bombay against the Forest Department, this time from Satara and Sindh. The Forest Commission will doubtless hear all and sundry of the aggrieved. It will be a fresh consolation to the latter to know that H. E. the Viceroy watches over their affairs with special care, because they are so especially poor and unrepresented.

THE partial destruction of the rice crops in China, consequent upon the recent floods, continues to attract large supplies of Burmah rice to China. The Chinese have chartered the S.S. *Somalia*, a vessel of respectable dimensions, for the transport of this cereal from Rangoon to Canton. Reports of a deficiency in Rangoon has stimulated large exports from Bangkok also.

IN connection with the Lucknow Exhibition of Arts and Manufactures to be held in November next, to which we drew attention in a recent issue, it might be advisable for the Local Committee to entertain the services of Mr. E. Doyle, O.E., as this is a department in which that gentleman would prove useful. Mr. Doyle would lay himself out energetically in furtherance of plans for carrying the success of the Exhibition.

COLONELS FRENDECAST and Hastad, R.E., Irrigation Department, and the District Engineer of South Arcot, arrived in Pondicherry recently, for the purpose of holding a conference with the French Government officials regarding certain irrigation works of importance, to both the French and British Governments.

THE total cost of the administration of the small French Indian Colony of Yanam for the current year of 1885 is 47,575 francs, equal to Rs. 23,094, or fully 25 per cent less than the pay and allowances of a single collector in British territory. The amount includes (1) chief administration charges, 4,391 francs; (2) public instruction 10,531 francs; (3) Judicial and Police, 10,002 francs; and (4) Medical services 6,614 francs; the balance being for Public Works, &c.

THE order of Mons. F. O. Regel, the Governor of the Dutch Settlements on the Coromandel Coast, dated 15th March 1819, and addressed to the inhabitants of Sadras and Mayur, has lately been produced on an enquiry made as to the taxes on certain poramams or back-yards in Sadras and Mayur. It recognizes the poramams as tax-free *inams* to be held in perpetuity, and the Government of Madras has decided to confirm these *inams* as tax-free grants in perpetuity.

ARRANGEMENTS have been made by the Survey Department for carrying out the survey work necessitated by the re-settlement of three districts of the Chittlagurh division—Raipore, Sambalpur, and Belaspore—the last of which yet have a full cadastral survey, with record of rights on the North-West Provinces system. Three full field parties will therefore be employed, one being brought from Malwa, another from Barmah, and the third from the Revenue Survey which has been going on at Ajmere.

THE *Japan Herald* states that the almost unprecedented quantity of rain which fell in Japan during the month of June has been the cause of widespread disaster, a large tract of country in the neighbourhood of Osaka having been inundated. No reliable estimate has yet been made either as to the number of lives lost or as to the extent of the damage. A high official estimated on Saturday, 27th June, that the number of bodies recovered was one thousand, but the number of lost is now roughly placed at fifteen thousand. The damage done was put at \$10,000,000, but now one would hardly care to suggest any sum that would cover the total loss of property.

THE lighthouse tender *Ceylon* has left Colombo for Minicoy, taking as passenger Mr. Rossett, the German scientist and explorer, who hopes to be able to collect a mass of information and objects such as were never before brought before the public. Mr. Rossett will be the first European who has made any thing like a complete exploration of the Maldive atolls. He takes introductory letters to the Sultan and his Prime Minister, Ibrahim Didi, and should he be successful, the Ceylon Court at the Exhibition will gain by the addition of a portion of his collection. The *Ceylon* will land him at the Male atoll, the most northern and approachable island, and nearest to Minicoy. Thence he will make his way southwards in native craft, passing from one atoll to the other. The *Times of Ceylon* remarks that as he is conversant with the Arabic language and is provided with ample means, and is moreover most courteous and agreeable in his manners, he will experience no difficulty in his labour of love, for such it is to him, though engaged in the services of others. He hopes to be back in Ceylon in about three months from the present time.

It would appear that the natives are awakening to the necessity of making some provision against the disasters of a future famine. The last dearth appears to have taught them that it is not wise to depend wholly on Government aid which in nine cases out of ten is misdirected, for we hear that a movement is on foot to organize in all outlying villages in the Mysore province funds to be utilised in relieving the needy during a famine. The fund to be raised will not consist of money alone, but grain also will be received as gifts towards it, and stowed away in granaries to be built for the purpose. Raggy will probably be the grain required, as it is the only one, as far as we are aware, that will keep for years, if kept dry, without deteriorating. It is estimated that twenty lakhs of raggy could be collected within a few years by receiving small money gifts from natives. The grain will be given away to ryots and others together with a sever of raggy in return for work done

by them, such as deepening of tanks, &c. This is the merest outline of the scheme, but it is proposed to ask some leading native gentlemen to convene a meeting for the purpose at which details will be arranged. The proposal is a benevolent one, and as such must commend itself to natives in general, and we wish the movement success.

Selections.

SUGAR-CANE AND SUGAR TRADE IN BRITISH BURMAH.

[Concluded from last week.]

Memorandum by Mr. J. B. BRIDGES, Director of Agriculture,—dated the 12th August, 1885.

22. *Modes of cultivation.*—Where new land is cleared, land already cultivated has been left fallow, the cultivator turns up the soil with a hoe at the beginning of the rains (May or June); he leaves the soil to rest until September when he digs holes about 18 inches deep and one foot wide at intervals of 1½ foot from each other. Three pieces of cane (agyaung), about five inches long, are then placed in a standing position in each of these holes, so that one end of each plant touches the ground and the other protrudes about an inch over the top of the hole. The cane-pieces are then partly covered up with loosened earth. There are generally three joints to each of the cane-pieces and each joint has one eye. Many of the young plants being, however, destroyed by the heat or other accidental cause, it is seldom that more than five or six canes are found to one stool.

23. Some cultivators plough their land three times at the beginning of the rains instead of turning it up with the hoe; but the more general practice is simply to run deep furrows through the land in September, and then place the cane-pieces longitudinally at the bottom of the breach, which is about ten inches deep and 1½ foot wide. The space left between the furrows varies from two to three feet, according to the nature of the soil.

24. Before the cane is planted, the land is cleared of grass and weeds. About 10 days after the cane-pieces have been planted, the earth is loosened in the intervals between the holes, and the cane-pieces further covered up with mould. In the month of Pyatho (beginning of January) the earth is again loosened, and the plants further covered up. About the month of Kazon (May) the land is again cleared of weeds and grass, and the plants are then left until the month of Wagaung or Tawthalin (August and September), when they are stripped of the leaves that have become old and withered.

25. After the second year's crop the land is either left fallow for a year, or again replanted with cane-tops and then left fallow the following year. Some portion of each plantation, except in very small holdings, is left fallow every year, as only enough cane is cut daily to supply the amount of juice required for boiling, and part of the land is still uncropped in Pyatho (beginning of January) when the sun is too hot to allow of cane-tops being planted. In land thus left uncultivated the cultivator often plants paddy for his food provision, after leaving sufficient space between the rows of paddy to put down cane-pieces in September.

The cane generally cultivated for manufacturing purposes is so flexible that it does not require any support; the canes are not therefore tied in clusters in these plantations in the manner described for plantations on the tidal creeks.

26. This is the system of cultivation followed in the Shwegyin districts, and the modes of cultivation adopted in the other districts differ but little from it.

27. *Area of plantations.*—The area of plantations in most districts is seldom over an acre; in the Shwegyin district, however, the area of the holdings is much larger; they measure three to four acres, and sometimes as much as 25 acres.

28. *Irrigation.*—Irrigation is seldom resorted to in the districts where cane is grown for manufacturing purposes. In exceptionally dry seasons the plants are sometimes watered in February.

29. *Rat-oning.*—There are generally three or four young shoots, or ratoons, which spring up from the old stool. Where those ratoons are sufficiently thick, no new plants are put down after the cane has been cut, but as a rule cane-tops (kyanbya) are planted (pha saik thi) in the intervals between the ratoons (kyanngat) after the land has been cleared of grass and weeds: these cane-tops are about five inches long and are planted from November to the beginning of January, when cane-pieces can no longer be planted. The cultivators state that one ta (0.23 acre) yields to

3,500 cane-tops, whereas one ta of cane yields enough cane-pieces to plant out five tas (1.40 acres). Cane sell at Rs. 20 per 1,000, whereas cane-tops sell at Rs. 2 per 1,000.

In Sandoway as many as three crops are obtained from the paungghyan, but the last crop is said to be very inferior, stunted, and contains but little saccharine matter. Two crops are sometimes obtained from the kyaung. In Mergui it is stated that the cane is only planted once every three years.

30. *Harvesting.*—In Burmah proper the cane blooms about the month of November; they are then covered with a dah from the stool close to the ground. The branches at the top are given to the cattle for food, and the top, which is cut off where the hard cane ends, preserved for planting. The canes are then divided with the dah into two pieces of about four feet each, tied up in bundles and carried by the cane-cutters to the mill, where they are bruised, and the juice extracted.

In Arakan the canes do not generally ripen until December, and the cane cutting does not begin until January.

31. *The Sugar Mill.*—The mill in general use in Burmah proper consists of two heavy upright cylinders of about one foot in length and two feet in diameter. The cogs are circular and are cut in two rollers superposed to the crushing cylinders. A shaft, about 12 feet long, is fixed at one of the upper cylinders, and is turned by a buffalo yoked to it.

32. A few improved machines are now used in Bhamo, and they consist of three upright pyingado cylinders, and the middle cylinder to which the shaft is attached, turns the other two by means of short, straight, wooden cogs: these machines have been made by a Burman, Maung San Dwa, who imitated an English machine he had seen in Moulmein. The price of the machine with two cylinders is about Rs. 50, and of that with three cylinders about Rs. 70.

33. In Arakan a mill of a much rougher description is used as its cost is given as only Rs. 5 in Sandoway, and in Kyaungpyu the til-seed mill (pestle and mortar arrangement) is in general use. In Mergui it appears that a stone-crushing press is used.

34. *Crushing.*—The canes, which have been previously cut short, are passed three times between the wooden rollers, being hauled back by a labourer, who collects them as they come out of the machine. The cane juice is received in a large bamboo frame, and thence flows through a bamboo gutter into an iron pan in the boiling shed.

35. The crushed cane (cane-trash, or megas) is dried in the sun for two days, and then used as fuel with branches of trees and dead wood brought from the neighbouring jungle.

36. *Boiling.*—The juice is carried in earthen pots from the receiving pan to the iron boiling pans, which are placed three in a row over a furnace dug in the ground. The fire is kindled at one end of the furnace and boils all the pans in succession on its way to the chimney. The liquor is at first placed in the pan furthest from the fire, and as it evaporates it is passed on by means of ladles to the next pan and from this to the pan immediately over the fire. It gets thicker as it passes along, and the impurities are removed by means of a wooden skimmer. In each pan is placed a bamboo framework to prevent the boiling juice from cascading over the sides of the pan. After the juice in the third pan has become sufficiently thick, it is taken off the fire and poured into an iron pan, where it is allowed to cool for a few minutes. It is then poured on a bamboo mat, spread evenly with a piece of bone, and then divided with a piece of pointed bamboo into small squares. After it has become hard, it is broken into cakes and packed away in bamboo baskets covered with leaves. Each basket contains about 175 lbs. of jaggery.

Cost of Cultivation.—The cost of the different kinds of labour hired for cane-cultivation is as follows:—

	Per ta (0.23 acre.)		
	Rs.	A.	P.
Ploughing	2	12	0
Clearing	1	10	0
Digging holes for plants	1	0	0
Planting	1	0	0
Loosening earth	2	0	0
Loosening earth (second time)	2	0	0
Clearing (second time)	2	0	0
Pruning	2	0	0
Cutting canes*	1	0	0
Seed	3	0	0
Total	25	4	0

* Two labourers are hired for cutting canes for each mill used; they are paid Rs. 15 each for mensem, without food, and they cut about one acre of cane a month, one-half of their hire being put down to cost of cultivation and one-half cost of manufacture: this would give about Rs. 4 as the cost of cutting canes per ta.

This hire includes the cost of keeping the labourers, which is by custom estimated at eight annas a man per sa.

33. The cost of cultivation in a plantation worked entirely with hired labour would, therefore, amount to about Rs. 100 per acre. The greater number of cultivators, however, hire little or no labour and work the land with their families. Those who work very large holdings generally hire their labourers by the year, and not by contract. The average cost of cultivation per acre may be estimated at Rs. 15 to Rs. 20.

39. The instruments used in cultivation, with their cost, are as follows:—

	Rs.	A.	P.
The plough, or sa	3	0	0
The curved hoe (dagauk)	1	0	0
The straight hoe (pauktu)	1	0	0
The da for cutting canes	0	8	0

40. Cost of Manufacture.—The cost per mensem of the labour employed in the manufacture of kyantaga (gur) is as follows:—

	Rs.
Two men cutting canes † at Rs. 5 each	10
Two buffaloes at Rs. 7 each	14
One herdman	7
One labourer to boil the juice	20
Food of labourers	15
Total	66

41. The monthly outturn for one furnace is generally taken as 1,250 viss of jaggery, and if the outturn per acre is taken as 1,000 viss, this would give us the cost of manufacture per acre Rs. 53 (Rs. 50). To this amount must be added the annual wear-and-tear of machinery, the cost of fuel, baskets, mats, &c., and the annual erection of crushing and boiling sheds.

42. The crushing machine costs Rs. 50, and it is stated to last about seven years; it works about three months annually, and takes one month to crush the cane of one acre. It, moreover, requires annual repairs, which amount to Rs. 3 or Rs. 4. The annual wear-and-tear for the machine would, therefore, be about Rs. 3.50 per acre. The boiling pans cost about Rs. 21, and are said to last about three years; as one set is used for each mill, the annual wear-and-tear per acre for boiling pans would be Rs. 2.30. Allowing Rs. 11.20 per acre for the share of other expenses, the cost of manufacture would amount to Rs. 60 per acre.

43. The labourers who cut the canes also pass them through the mill. The herd man not only grazes the buffaloes, but drive them whilst turning the mill and carries away the cane trash to dry. The labourer who boils the juice also breaks the jaggery into cakes and packs the cakes away in bamboo baskets.

44. Although the hire of these labourers is always given by the month, they in reality work by contract. The headman has to boil daily seven *kyans* (iron can containing 90 12 gallons of juice, yielding from 150 to 196 lbs. of jaggery, (according to the season), the labourers cutting the canes have to supply and pass through the mill a sufficient number of canes to yield seven *kyans* full of juice. If the full monthly outturn is not obtained, the pay of the labourers is reduced in proportion to the deficiency. Some headmen make 10 *kyans* of kyantaga a day, their pay then rises to Rs 25 per mensem, and another cane-cutter and buffalo have to be hired.

45. Yield per acre.—The following table shows yield per acre according to the experiments made by District Officers:—

	Number of canes per acre.	Weight of canes per acre. lbs.
Arakan		
Akyab
Kyaukpnyu
Sandoway (estimate)	5,000	36,500
Pegu		
Pegu (northern portion)†	3,000 (estimate)	...

The following shows the yield per acre in juice and kyantaga (gur):—

	Amount of juice per acre. lbs.	Weight of kyantaga per acre. lbs.
Arakan		
Akyab
Kyaukpnyu
Sandoway	...	2,482

† One-half of this has been put down to cost of cultivation.

	Amount of juice per acre. lbs.	Weight of kyantaga per acre. lbs.
Pegu		
Tharrawaddy
Proma
Irrawaddy		
Henzada
Thayetmyo
Amherst	11,822	2,759
Shwegyin	22,566	3,452
Tenasserim		
Toangoo
Tavoy
Mergul	10,950	2,566

46. Selling price of jaggery.—The selling price of jaggery at the beginning of the season varies from Rs. 35 to 30 per 100 viss; later in the season the price falls to Rs. 25 and 20; and for two years it is said to have fallen as low as Rs. 9 per 100 viss. The cultivators generally agree in taking Rs. 25 per 100 viss as the average price, and this price may be taken as a fair average.

47. Average profits.—In holdings worked entirely with hired labour the cost of cultivation amounts to Rs. 90, and the cost of manufacture to Rs. 60 per acre. The average outturn per acre (3,500 lbs. at Rs. 25 per 100 lbs.) is worth Rs. 87.50; the net profit per acre, not including cost of living, should therefore be Rs. 100. In small holdings the cost of cultivation has been estimated at Rs. 20 per acre, and the cost of manufacture being Rs. 60, the net profit would amount to Rs. 170 per acre. In small holdings which do not measure more than one acre, the cultivator spends all the profits in supporting himself and his family, and in the larger holdings the profits of cultivation often go to pay the interest on money borrowed.

48. Condition of the cane-cultivators.—The cultivators are everywhere the manufacturers, but in most districts they only cultivate small areas of cane and also grow paddy. No information regarding the condition of these cultivators is available, and it does not probably differ much from that of the general body of cultivators. In Shwegyin, however, where the cultivators grow exclusively sugar cane, it has been found that more than half of them are in the hands of Burmese and Chinese money-lenders, who advance them money at the rate of 48 or 60 per cent, and also compel them to sell their kyantaga in advance at 30 or 40 per cent below the market value, so that the rate of interest in reality amounts to 100 or 150 per cent.

49. Local consumption and import.—Taking the total area under cane in the permanent tract to be 7,000 acres, the average outturn at 2,800 lbs. of gur per acre, the amount of sugar produced in one year would be 8,750 tons; the whole of this is consumed in British Burmah, excepting small quantities exported from the Akyab district into Chittagong.

The import of sugar into British Burmah during the last five years has been as follows:—

	Foreign ports. Cwts.	Indian ports. Cwts.	Upper Burmah.* Cwts.
1880-81	47,636	16,008	187,551
1881-82	48,575	37,894	199,377
1882-83	37,600	26,835	231,782
1883-84	23,751	40,216	202,898
1884-85	33,310	44,772	295,285

Refined sugar is consumed only by Europeans and Burman traders in the large towns, and the imports of this kind amounted last year to 78,869 cwts.

50. Direction in which improvements may be effected.—Attempts have been made to improve the cultivation, especially in the Shwegyin division, by introducing new kinds of cane. Canes from Northern India and from Penang were imported, but none of the North India canes, and only a few Penang canes, are thriving at Billu, and the supply of them was so small that they have only been used for seed stock, and none of them have as yet been crushed.

51. Cane stock from the Billu valley was introduced into the Salween district by Government, and a small cane farm maintained at Papun for the purpose of distributing cane stock. A large number of cane-tops and cane-pieces were distributed, and it is believed that cane-cultivation has now obtained a firm footing in that district. The canes grown there were 8 feet long and about 7 inches thick, and the kyantaga manufactured from their juice was said to be better than that of Billu, and sold at Rs. 45 per 100 viss.

An attempt will be made to introduce cane-cultivation into the Arakan Hill Tracts during the coming season.

* This sugar from Upper Burmah is made from palm-are sap.

52. Four of Messrs. Thompson and Mylne's mills were sent to Billin in 1882. The cultivators tried them for some time and did not continue to use them, as they objected to the small size of the cylinders and to the shortness of the shaft. They asked for mills with hollow cylinders of a diameter of 1½ foot and a length of one foot, as they thought this would increase the speed of the mill without any additional strain on the cattle.

It was not possible to comply with the request of the cultivators until Mr. Mylne had personally ascertained the validity of their objections. Mr. Mylne visited Billin at the beginning of this year, and after examining the Shan mill in ordinary use, he considered that the Shan mill was the best Native mill he had seen in any part of India, and he attributed the inferiority of the Shan mill to the want of a better method of making the mill (phingado or iron) and to the want of the draught-power of Burmese cattle, which is not of the same kind as that of a large-sized mill. He then proposed to have made in Billin a double-flange mill of a larger size than any hitherto sent out to India, and he tried it at Billin at the end of the year.

53. Mr. Mylne was of opinion that the Shans have little to be taught in the art of planting cane, and that their mode of cultivation was superior to that generally adopted in India. He pointed out, however, that many of the canes in the plantations were laid on the ground, and this would yield a more acid juice than straight canes. He illustrated this by testing the density of the juice of three straight canes, which was found to be nine according to Reame's saccharometer, whereas the juice of bent or laid canes only gave 7½. The Shans admitted that the juice of some of the laid canes was so acid that it could not be manufactured into kyantaga; but they appeared to think that it would be too troublesome a task to tie the canes of one stool together so as to prevent them from falling.

54. Mr. Mylne considered that the Shan method of preparing and boiling the juice was defective, as the wickerwork frame used in boiling, the receiver, conductor, and receiving-pan are not kept free from the germs of fermentation, and the juice is consequently somewhat acid before it is boiled. He added that the juice is always more or less burnt in the Burmese pans, and, therefore, produces a smaller quantity of crystallizable sugar. He recommended the Shans to uncover the juice conductor, which is usually a hollow bamboo buried in the ground, and showed them how to destroy the germs of fermentation in the different implements used by fumigating them with sulphur.

55. Mr. Mylne was accompanied by a native of Behar, who showed the Shans and Burmans the improved methods of boiling the juice in a shallow pan after clarifying it with a decoction of the rind of the root of the *Abelmoschus esculentus* (lady's-fingers) and of the crushed seed of the *Ricinus communis* (castor-oil plant). Three boilings were made of—

- (a) gur (not clarified) with juice from Burman mill evaporated in Behea pan;
- (b) kyantaga (not clarified) with juice from the Burman mill evaporated—(a) in Burmese pan, (b) in Behea pan;
- (c) rab (not clarified) with juice from the Behea mill evaporated in Behea pan.

56. The jaggery thus made was afterwards analyzed with the following results:—

	Kyantaga, gur, evaporated in their pans; juice from Burmese mill.	Kyantaga evaporated in Behea pan; juice from Burmese mill.	Gur (not clarified) boiled; juice from Burmese mill.	Dry rub made by Maung San Dwa, Burmese mill.	Crystallizable sugar, prepared by Maung San Dwa, Burmese mill.	Crystallizable sugar, prepared by Maung San Dwa, Burmese mill.
No. 1	No. 2	No. 3	No. 4	No. 5	No. 6	No. 7
Crystallizable sugar	68.65	68.66	68.67	68.68	68.69	68.70
Uncrystallizable sugar	10.75	9.43	10	10.75	10.75	10.75
Water	7	6	7	7	7	7
Ash	5.1	5	5	5.1	5.1	5
Soluble organic matter	20.56	14.09	21.70	20.56	14.74	14.74
Insoluble organic matter	5	5	5	5	5	5
Non-sugar matter by Co. 1	100.00	100.00	100.00	100.00	100.00	100.00
	48.24	56.56	47.4	54.97	73.88	73.92

* No. 1 is the rub obtained by a Burman trader in his attempt to make refined sugar. This is noticed in the next paragraph.

Sample No. 6, termed "molasses," is, as will be seen from the above figures, much better than it is named. It contains a lot of crystallizable sugar freely separating out, and when freed from its moisture by drying at 100° C., becomes a fairly good "rub."

Mr. Mylne makes the following remarks on this article:

"No. 1 (Billa kyantaga) as a basis of comparison, No. 2 shows a gain of 8 per cent in crystallizable sugar; this is obtained by evaporating the cane juice in the flat, open pan with a very much larger area of evaporating surface in proportion to bulk, as combined with the small, round, deep pans at present used there. No. 3 shows a loss of 0.84 per cent in crystallizable sugar, consequent, we believe, on its being from the first trial of the open pan at Billin and before the pan had been properly cleaned by use.

"No. 4 shows a gain of only 1.44 per cent after all the expense incurred on it by Maung San Dwa.

"No. 5 shows a gain of 17.28 per cent, due entirely to the care with which the cane-juice was kept from contact with germs of fermentation, this being effected by—

- (i) crushing the cane between iron rollers;
- (ii) receiving the juice in a fumigated, portable receiver, and
- (iii) transferring it at once to the shallow pan, where it was further clarified by a cold infusion of the rind of the root and stem of *Abelmoschus esculentus* (lady's-fingers), or in short "antural," and also by a cold infusion of the bruised seeds of the castor plant.

"No. 6. This is the molasses drained from No. 5, and shows that there was 45.31 per cent of crystallizable sugar remaining in it, with rather less uncrystallizable sugar than No. 1. The last two of figures gives the crystallizable sugar in each sample. It is evident that No. 6 (the molasses of No. 5) could be made into a fairly good gur or kyantaga.

"No. 5 is a very clean, pure sugar, and till a good crystallizing rub can be produced, it might suit Maung San Dwa to make this kind of sugar to brew it down into what is known here as 'blura.'

"We doubt if a good rub, such as D, can be produced from the loose, light loam of the Billin valley. Here we get it from a good, clay, loamy soil. There are extensive areas of this kind of soil in Burmah on a slightly higher level than the stiff clay lands."

"It is not possible to say whether the cane-cultivators will follow the improved methods of manufacture shown to them. The shallow Behea pan was left with them, and next season will show whether they consider it advisable to adopt it.

"Several attempts have been made at Billin by Burmans and Chinese to manufacture refined sugar, but hitherto without success. The last attempt was made in 1884 by a Burman, named Maung S. Dwa, according to a method probably of Chinese origin. He bought large quantities of kyantaga (gur), and after boiling it again, placed the thick syrup thus obtained in earthenware pots. The sugar gradually granulated and the molasses was drained off from the bottom of the jars. The sugar then left in the jars was whitened by covering it with a layer of earth mixed with honey and herbs; the sugar was removed as it whitened and the layer of earth applied to the lower sugar until the whole contents of the jars had been treated in this manner. He was, however, unable to utilize the molasses drained off, and the sugar he obtained was very coarse and dark in colour, so that he was only able to sell it for about Rs. 45 per 100 viss, and lost a considerable amount of money in this experiment.

"Mr. Mylne visited Maung San Dwa's refinery. He attributed his failure to the want of proper appliances, and to the method adopted in boiling the juice. Mr. Mylne did not advise the establishment of a refinery at Billin, but the introduction of a mill is now in use in India. He offered to show Burmese cultivators the methods of manufacturing in India. This offer has been accepted, and Maung San Dwa and a Shan cultivator will proceed to India next year at the expense of the local Government to study improved methods of sugar manufacture.

61. Advances have been made by Government to the cultivators of the Billin and Thebyn valleys, who were found in a state of chronic indebtedness. In 1883 about Rs. 7,000 were advanced to the cultivators and fully recovered in the following year. In 1884 Rs. 20,000 were again advanced, but a sum of about Rs. 7,000 has not been recovered owing to a low yield of sugar, due to heavy floods and to a fall of about 30 per cent in the price of kyantaga. A further sum of Rs. 30,000 has been advanced during the present year, and it is hoped that the whole amount, with the arrears of 1884 will be recovered during the next season. It is believed that the result of these advances has already been a slight reduction in the rates of interest and the improvement of the condition of the cultivators. Such an experiment will have, however, to be continued for several years, if it is expected to have any lasting results, and it is as yet early to judge of the success of the experiment.

"A species grows all over this country, Beluchistan, Afghanistan, Cashmere and Western Tibet which seems to be identical with the species received.

"A species grows all over this country, Beluchistan, Afghanistan, Cashmere and Western Tibet which seems to be identical with the species received.

In Boluebia, as it is, as well as a totally distinct plant, *Periploca* *aphylla*, called *Hans*. It grows equally on exposed hills and valleys, one mass of upright twigs, each twig, if you notice, being made up of joints like the joints of the fingers. The bush (from 1 to 2 feet) is golden coloured, and the twigs are more or less so. This plant has no leaves. It is all twigs and joints.

"Owing to a general likeness of the stiff red-like growth upright and erect, of the two plants, in Beluchistan, the natives equally give both the same name.

"No one would mistake the jointed and tens, them for the non-jointed falcon," said Partridge. "The latter does not exist here at all."
"It is mythical," he here in response, to mix with snuff, being first of all a name. The names cast in and by more irritating whether they are decorative, or to the upper gum under the part of the bill, as is the rabbit here"—I turn, &c.

Vol. 2, August 29, 1825

COLONISATION IN INDIA

Before long we shall probably see an extensive emigration of the cultivating classes from the crowded districts of the Provinces to the new lands of the Punjab, or perhaps to the sparsely-populated countries of Rajputana and Central India. All experience of the process of colonisation will therefore be extremely useful to Government, for a little experience will help the authorities to avoid all mistakes and blunders which might check and seriously injure one of the most important and desirable of the economical movements of the day. In the last Report written by Sir Henry Renssley or Kamaon, a few words are said about colonisation, and they would seem to indicate in a simple manner the policy which must direct the establishment of new villages on new lands. Sir Henry writes—"As a rule, I allow a new village to have the land free for two years, that the settlers may clear the jungle, build their huts, and get the land into order. The third year four annas a bigha is charged, next year six annas, and then eight annas." And no doubt with these concessions and under Sir Henry's fostering care colonisation went on apace. But something more than revenue concessions will be wanted at first, and leaders to conduct the emigrants will be necessary. The young colony must be kept together, and must have some headman to look to for guidance; and whether this headman be an agent of Government or a man of authority from the parent village, the success or failure of the movement will almost entirely depend on him. It is the fashion to say now-a-days that the village community is breaking up, and that the tendency of the times is towards a severalty of interests. We cannot controvert this, but we do maintain that in the colonisation of new land on a large scale the village community will play a prominent part, and that the communal system will take a new lease of life, and it would be a mistake to look for any deduction on the part of the emigrants, or to ignore the element of joint dependence, which is the product of ages. The colonisation of new land will be a movement of the greatest interest, and may lead to results as yet undreamt of by the natives of India. When once the plunge has been taken, and the old district changed for a new one, there will be little hesitation in going further afield, and a mobile population will seek new provinces, and perhaps new continents. With a few black-bands and buffaloes, the sturdy cultivator of Northern India will make any land his home.

A SKILFUL SURGICAL OPERATION.

The American Ambassador at Vienna, Mr. Kasson, has lately forwarded to his Government an interesting account of a remarkable surgical operation lately performed by Professor Billroth, of Vienna, which, wonderful to tell, consisted in the removal of a portion of the human stomach, involving nearly one-third of the organ--and, strange to say, the patient recovered--the only successful operation of the kind ever performed. The disease for which this operation was performed was cancer of the stomach, attended with the following symptoms:--The appetite is quite poor. There is a peculiar indescribable distress in the stomach, a feeling that has been described as a faint "all gone" sensation; a sticky slime collects about the teeth, especially in the morning, accompanied by an unpleasant taste. Food fails to satisfy this peculiar faint sensation; but, on the contrary, it appears to aggravate the feeling. The eyes are sunken, tinged with yellow; the hands and feet become cold and sticky--a cold perspiration. The sufferer feels tired all the time, and sleep does not seem to give rest. After a time the patient becomes nervous and irritable, gloomy, his mind filled with evil forebodings. When rising suddenly from a recumbent position there is a dizziness, a whistling sensation, and he is obliged to grasp something firm to keep from falling. The bowels constive, the skin dry and hot at times; the blood becoming thick and stagnant, and does not circulate properly. After a time the patient spits up food soon after eating, sometimes in a sour and fermented condition, sometimes sweetish to the taste. Often-times there is a palpitating of the heart, and

THE HAGMA PLANT OF THE LAGOS

TO THE EDITOR OF THE "TIMES OF I. A."

Six. With reference to a paragraph in your issue of the 27th instant, on the soma plant, I think the following extract from a letter of Dr. Aitchison will be interesting to some of your readers, especially to the Parsees. The letter is dated 23th June 1886, Turbat Suika Jam, Persian territory. On learning that this eminent naturalist was engaged in making inquiries about the soma plant, in the flora of the mountain regions of Afghanistan, I sent him a short description of the *Asaorus* (soma) plant as found in the Avesta books of the Parsees, together with a few twigs of the plant used by the Parsees of Bombay. These twigs were specially sent for from Persia by Mr. Ardabeh Sorabjee Dastoor, the energetic secretary of the Persian Zoroastrian Amelioration Fund. The learned naturalist writes:—

"The specimens you sent me are the twigs of a species of *Ephedra* of the order *Euphorbia*."

the patient fears he may have heart disease. Towards the last the patient is unable to retain any food whatever, as the opening in the intestines becoming closed, or nearly so. Although this disease is indeed alarming, and runs with the above-named symptoms should not feel nervous, for nine hundred and ninety-nine cases out of a thousand have no cancer, but simply dyspepsia, a disease easily removed if treated in a proper manner. The safest and best remedy for the disease is Seigel's (Germine) Syrup, a vegetable preparation sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White (Limited), 17, Farringdon Road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

ST. MARK STREET, LONDON, E.C.

November 29th, 1891.

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years with dyspepsia; but after a few doses of the Syrup, I found relief and after taking two bottles of it I feel quite cured.

I am, Sir, yours truly,

Mr. A. J. WHITE.

WILLIAM BRENT.

September 8th, 1883.

Dear Sir,—I find the sale of Seigel's Syrup steadily increasing. All who have tried it speak very highly of its medicinal virtues; one customer described it as a "Godsend to dyspeptic people." I always recommend it with confidence.—Faithfully yours,

(Sd.) VIRGINIA A. WHITE.

To Mr. A. J. WHITE, Chemist, Dentist, Mothay's Fyall, Seigel's Operating Pills are the best family physic that has ever been discovered. They cleanse the bowels from all irritating substances, and have the effect of a healthy condition. They cure constipation.

Preston, Sept. 21st, 1883.

My dear Sir,—Your Syrup and Pills are still very popular with my customers, many saying they are the best family medicine possible.

The other day a customer came for two bottles of Syrup and said "Mother Seigel" had saved the life of his wife, and he added, "one of these bottles I am sending fifteen miles away to a friend who is very ill." I have much faith in it.

The sale keeps up wonderfully, in fact, one would fancy almost that the people were beginning to breakfast, dine, and sup on Mother Seigel's Syrup; the demand is so constant and the satisfaction so great.

To A. J. WHITE, Esq.

Spanish Town, Jamaica, West Indies, October 21, 1892.

Dear Sir,—I write to inform you that I have derived great benefit from "Seigel's Syrup." For some years I have suffered from liver complaint, with its many and varied consequences, so that my life was a perpetual misery. Twelve months ago I was induced to try Seigel's Syrup, and although rather sceptical, having tried so many reputed infallible remedies, I determined to give it at least a fair trial. In two or three days I felt considerably better, and now at the end of twelve months (having continued taking it), I am glad to say that I am a different being altogether. It is said of certain peas that they "come as a boon and a blessing to men," and I have no reason to doubt the truthfulness of the statement. I can truly say, however, that Seigel's Syrup has come as a "boon and a blessing" to me. I have recommended it to several fellow-sufferers from this distressing complaint, and their testimony is quite in accordance with my own. Gratitude for the benefit I have derived from the excellent preparation, prompts me to furnish you with this unsolicited testimonial.

I am, dear Sir,

Yours ever gratefully,

(Signed) CARRY B. LIZANT.

Baptist Missionary.

A. J. WHITE, Esq.

Henningsham, Whitehaven, October 18, 1892.

Mr. A. J. WHITE,—Dear Sir,—I was for some time afflicted with piles, and was advised to give Mother Seigel's Syrup a trial, which I did. I am now happy to state that it has restored me to complete health.—I remain, yours respectfully,

(O)

(Signed) JOHN H. LIGHTFOOT.

HOLLOWAY'S PILLS.—Wrongs made Right.—Every day that any bodily suffering is permitted to continue renders it more certain to become chronic or dangerous. Holloway's purifying, cooling, and strengthening Pills are well adapted for any irregularity of the human body, and should be taken when the stomach is disordered, the liver deranged, the kidneys inactive, the bowels torpid, or the brain muddled. With this medicine every invalid can cure himself, and those who are weak and infirm through imperfect digestion may make themselves strong and stout by Holloway's excellent Pills. A few doses of them usually mitigate the most painful symptoms caused by undigested food, from which they thoroughly free the alimentary canal, and completely restore its natural power and action.

HEALTH FOR ALL!!! HOLLOWAY'S PILLS & OINTMENT.

THE PILLS

Purify the Blood, correct all Disorders of the

LIVER, STOMACH, KIDNEYS, AND BOWELS.

They invigorate and restore to health Debilitated Constitutions, and are invaluable in all Complaints incidental to Females of all Ages. For Children and the aged they are priceless.

THE OINTMENT

Is an infallible remedy for Bad Legs, Bad Breasts, Old Wounds, Sores and Ulcers. It is famous for Gout and Rheumatism. For disorders of the Chest it has no equal.

FOR SORE THROATS, BRONCHITIS, COUGHS, COLDS,

Glandular Swellings, and all Skin Diseases, it has no rival; and for contracted and stiff joints, it acts like a charm.

Manufactured only at THOMAS HOLLOWAY'S Establishment,

78, NEW OXFORD STREET (late 533, OXFORD STREET), LONDON.

And are sold at 1s. 1ld., 2s. 6d., 4s. 6d., 11s., 22s., and 33s. each Box or Pot, and may be had of all Medicine Vendors throughout the World. Purchasers should look to the Label on the Pot and Box. If the address is not 78, New Oxford Street, London, they are not the genuine.

INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X7

CALCUTTA:—SATURDAY, SEPTEMBER 19, 1885.

[No. 98.]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING 9TH SEPTEMBER 1885.]

General Remarks.—In Madras rain in varying quantities has fallen in all districts, but more is urgently needed in several places, especially in Bellary, Coimbatore, Madura, and Salem. The reports from Bellary are very discouraging. Rain continues to hold off in Mysore; crops are generally reported to be withering, agricultural operations are at a standstill, and the prospects of the dry crops are critical, and entirely dependent on a very early fall of rain. Fodder is becoming scarce, and the migration of cattle from Kolar into British territory is reported. In Coorg prospects continue favourable.

In Coorg prospects continue favourable. Slight rain has fallen throughout the Bombay Presidency, excepting Sindh; but more is urgently required in several parts of the Deccan and Southern Mahratta country, where fodder is scarce. In parts of Poona, Ahmednugger, Dharwar, Bijapore, and Belgaum the crops are withering for want of rain. They have been injured by floods and insects in parts of Kurrachee, by blight and worms in parts of Hyderabad, and by excessive rain in parts of Surat. In the Berars and Hyderabad, rain is wanted for the standing crops, which are at present doing well. Rain has fallen generally throughout the Central India States, and the crops are doing well. In Manipore, however, rain is much wanted. In the Rajpootana States, rain has been almost general, and prospects are satisfactory.

are satisfactory. In the Central Provinces, agricultural prospects continue good; but more rain would be beneficial in Nimar and the southern districts, where the break has been of long duration. In the North-Western Provinces and Oudh, rain has fallen in several districts; but a break has set in to the advantage of the crops, which have already suffered from excessive rain. Prospects are, on the whole, good. Moderate rain has fallen in most parts of the Punjab, and *Khart* prospects are generally good.

In Bengal, rain has fallen in all districts, and a break is now much needed for the crops. Excessive rain and floods have caused considerable damage in parts of Burdwan and the Presidency Divisions, and some injury to the *Madar* crops in places in Behar and Chota Nagpore. Seasonable weather prevails in Assam, where agricultural prospects are generally good.

generally good,
In British Borneo, ploughing and transplanting have been nearly
completed.

Cholera continues in the Madras and Bombay Presidencies and in Raipur in the Central Provinces, and in some districts of the North-Western Provinces. Elsewhere the public health is generally fair. Prices are rising in Bengal and Mysore; in the Punjab they are falling, and elsewhere they are generally steady.

Madras.—General prospects discouraging in Madura, Coimbatore, and Salem, especially so in Bellary. More rain urgently needed in several districts besides these.

Summer.—Bright rain throughout the Presidency, excepting Sind ; more required urgently in several talukas of the Deccan and Southern Mahratta country districts, and in parts of Kaira. Crops withering in parts of Poona, Ahmednugger, Dhawer, Bijapore, and Belgaum, and damaged by floods and insects in parts of Kurrachee, by blight and worms in parts of Hyderabad, and by excessive rain in parts of Surat ; fodder scarce in parts of most districts in the Deccan and Southern Mahratta country. Cholera in parts of sixteen, fever in parts of ten, and cattle disease in parts of eight districts.

and cattle disease in parts of eight districts. Rainfall in all districts during the week; a break of fine weather, however much needed for all crops in many districts; excessive rain and floods have caused considerable damage in parts of Burdwan and Presidency Divisions, and some injury to *khadoi* crops in places in Behar and Chota Nagpore, elsewhere prospects of crops are favourable. Prices of rice rather higher in several districts. Public health continues generally fair, but fever is appearing in some districts.

N. W. Freeman and Co..—Rain has fallen in some districts; a frost has set in to the advantage of crops, which have already suffered from excessive heat. Provisions are, on the whole, good. Markets are well supplied, and prices generally steady. Cholera continues to be reported from a few districts.

Punjab.—Moderate rainfall in most districts. Health and harvest prospects generally good. Prices falling in the Hissar and Jullundur districts; stationary elsewhere.

Central Provinces.—Rain wanted in Nimar and in the southern districts, where there has been a long break; elsewhere there has been no deficiency. Prospects continue good.

British Borneo — Cholera severe in one district, slight in three districts, elsewhere public health good ; cattle-disease slight in seven districts, elsewhere health of cattle good. Ploughing and transplanting nearly completed. Rains seasonable.

nearly completed. Rains seasonable.
 Assam.—Weather rainy. Fevers prevalent; cattle-disease still re-
 ported from some mizalms. Transplants of tea or sub almost finished;
 prospects of all crops good. General health good.

prospects of all crops good. General health good.

Mysore and Coorg.—Rain continues to hold off and crops generally reported to be withering; agricultural operations almost at a standstill; prospects of the dry crops critical, and the future entirely dependant on a very early fall of rain. Drinking-water failing, and fodder for cattle decreasing; leaves being used as fodder in parts of Bangalore, Tumkoor, and Kolar; from the last-named district some reports are reported to have removed their cattle into British territory. Cattle poor; cattle-disease prevails in parts; cholera and fever in Mysore, but public health generally fair. Prices slowly rising.

generally fair. Prices slowly rising. *Bepar and Hyderabad.*—Weather cloudy. *Kharif* crops doing well, but require more rain. Wheat 15½, coarse rice 2½, white *mart* 18½, yellow *mart* 22, and tur 15½ sears per current stock prices. *Chann* thriving. Health

Central India States.—Weather clear. Crops thriving. Health generally good.

Rejozani.—Tanks and wells full. Prospects good; crops on low lands have suffered much from late inundations. Health good. Prices steady. Fine weather.

Nepal.—Prospects good. Cholera ceased.

Letters to the Editor:

CULTIVATION OF THE ORANGE

TO THE EDITOR,

SIR,—I shall be much obliged if you can give me any hints on the cultivation of orange trees in India. I don't want to know about the climate, because no place is better adapted to growing oranges than the place I have selected. I wish to know what distance apart the trees ought to be planted, when they will fruit, and how much fruit they will yield; also what extent of land should be planted to yield a sufficient return to pay for superintendence and up-keep, with a profit of Rs. 6,000 annually.

If you could let me know whether there is a good market for oranges in Calcutta, and what prices they fetch, it would be an additional obligation.

Vizagapatnam, 31st August 1885.

NETE.—The orange should be raised by budding on the common lime or lemon. The operation should be performed in February. In the December following, the young trees should be planted out at a distance of 20 feet apart, in large holes 2 feet deep and 5 feet diameter, filled with a rich soil composed of well-decayed cow-dung, night-soil, common black earth, and a small quantity of minked lime. The trees blossom, as a rule, in February and March, and the fruit is ripe by November, and sometimes earlier. They last till the end of January, and some times February; but the fruit should, for the sake of the trees, be all removed by January, to allow the plants to rest a little before flowering again in February. The soil should have a top-dressing of manure every year just before the trees begin flowering. We have known them to yield 3 or 4 years old, will yield from 50. to 500 fruits. We have known them to yield a great deal more. It is difficult to say what extent of land should be planted to yield the revenue our correspondent names; but we should think from five to eight acres would be sufficient. The price of labour and material, as well as the markets in different parts of India vary so considerably, that much would depend upon local conditions. Oranges certainly find a good market in Calcutta. The average price for really good fruit, during the height of the season, is the four annas per mure. They are much dearer at the beginning and end of the season. Calcutta is plentifully supplied with this fruit from Mysore, whence the season commences, and we should not think their importation from Visagapatnam would prove profitable to the growers, unless they came at a time when the existing supply was falling off. In conclusion, we may add that the orange is a good feeder, and requires to be kept well watered when the fruit is setting.—*Ed., &c.*

Editorial Notes.

AMONG our selections will be found an interesting paper on a French Open-air Silo. This is the first one of the kind we have heard of, but doubtless others will soon be following the example. Perhaps before long, the question, 'how will I build a silo?'—will cease to trouble farmers and others engaged in ensilaging fodder.

THE Government coffee crop in Java for the end of June 1885, was estimated at 611,890 piculs, or only above one half of the average yearly yield. The coffee belonging to private individuals exported from Java during the first two quarters of the year also shows a falling off of about 36 per cent, when compared with the quantity exported during the corresponding period of last year.

At a meeting of the Executive Committee of the proposed Agricultural Exhibition, held on Sunday, the 6th instant, at the hall of the Chisura Club, it was resolved that, as the greater portion of the district of Leicestershire had suffered much from the flood caused by the late rains, it was not advisable to hold the Agricultural Exhibition during the ensuing cold weather. The Committee have judiciously postponed the Exhibition, as it will take some time for the country to recover from the effects of the flood.

THE following is quoted as an instance of the great falling off in the price of land in England. At Spalding in Lancashire, a good farm of 110 acres was offered for sale, but the highest bid received £2,370, or about £21 10s per acre, and it was consequently withdrawn. This very farm when put up for auction in 1875 was bid for at £0,250, or nearly £57 per acre, but the vendor refused to sell, as he did not consider it a sufficiently high price. Since then £2,000 had been spent in protecting the farm from an adjoining river.

WE understand that the Bombay Abkari Commissioners have been recently instructed to include the item of fresh toddy in their programme of inquiry. This will give general satisfaction. What is now wanting to make the Commission a success, is to enable it to visit a few of the mofussil towns, say Thana, Alibag, Sarat, and Broach. Their tour will not cost much to speak of, and it will allay popular excitement once for all. The Commissioners, too, may enjoy a cold weather trip to Gujarat, and a flaggon of toddy may not come amiss to any of the worthy trio.

THERE is a prospect that we may soon cease to see ginger grown in Jamaica, which has so long held a high place in the market; for according to the *British Trade Journal*, "the cultivation of ginger in Jamaica is said to be dying out, on account of the persistent cultivation of the same plant on the same land for a long series of years. Only the richest and best lands are suitable for the cultivation of ginger, and, as it is a very exhausting crop, the production of the article on the island depends on the reserve of good land still available where it is cultivated."

THE Secretary to the State Board of Agriculture, U. S. A., has intimated that no report will be issued by the Board for August, but has stated that the estimate for wheat is 46 per cent of full crop, or 18,881,822 bushels. The corn is said to be doing finely, and now promises an average crop of 90,000,000 to 100,000,000 bushels. Oats are reported to cover a very heavy and large area, and may give 30,000,000 or 20 per cent above an average full crop. Hay, wheat, and oats are nearly all secured, and are in good shape; hay at a three-quarter crop, while pastures are good.

A CONTEMPORARY says:—

The Mysore Government, having in mind the famine of 1877, have taken the precautions to try and meet the impending one

with caution. We learn that two Executive Engineers proceeded the other day, one to Tankur, and the other to Kolar, to form estimates for all available relief works. Two other Engineers have also been ordered by the Dewan to be in waiting to proceed at a moment's notice, to such places as the Dewan may direct. A visitor to Kankanhully states that the crops are all withering, and the roots are very much depressed in spirits, and expects that if the rains should hold off for another week, they will have to meet the famine with a vengeance.

ACCORDING to the *British Trade Journal*, "rice occupies no less than one-half of the cultivated land in Japan, where there are 250 varieties of seed. Probably no country raises such a variety of leguminous plants for food. It is characteristic of the manner in which the French have waged the war—or, to be quite correct, the 'military operations'—against the Chinese that they declared rice to be contraband of war. This is the first time in history where provisions have been so treated, except in cases where they were being conveyed to a beleaguered city, or for the relief of an army threatened by starvation. International law will very soon have to be re-written, with annotations by M. Ferry."

WE have received, though a little late in the season, a copy of the Official Record of the New South Wales Commission for the (Akutla) International Exhibition. It comprises the report of the President, with appendices, some other reports, and an abridged catalogue of the New South Wales exhibits and list of awards. It is illustrated with photographs of the various New South Wales courts, while the frontispiece gives a general outside view of the Exhibition building. It is also accompanied by a ground plan of the New South Wales courts. The report is a comprehensive one, and is a credit to the Australians, who evidently take much pride in the excellence of their products as evidenced by the appreciation shown for them at the great show.

WE understand that a parcel of Khaki cotton, grown experimentally by Mr. A. Randle, of Wanowrie, has just been manufactured into drill at the Yerrowda jail. The cloth is said to be of a dun, or rather fawn colour, suitable for soldiers' uniforms, and of course needs no dye. Mr. Randle is of opinion that such cotton would be profitable as an annual field crop in that locality. The yield is reported as good, and the plant needs no irrigation. It seeds so freely that cultivation could be rapidly extended. It may be noted that this Khaki cotton is perhaps nothing more than the "Nankin" variety which has so long been cultivated in many parts of India. We remember to have seen, some years back, cloth of very good quality manufactured at the Jeyppore jail from Nankin cotton raised by seed on the jail grounds. The color is perfectly 'fast,' and no amount of washing will change it.

THE Foreign Sugar Bounty question has greatly exercised the English people, for we learn from a home contemporary, that at a meeting of the leading workmen of the sugar trade in Liverpool, on the 23rd July, to consider the question of a law to meet the competition of the foreign bounties system, resolutions were passed condemning the system, and agreeing to appoint delegates to accompany a deputation to the Prime Minister, to direct his attention to the urgent necessity of providing an efficacious remedy to neutralise the foreign bounties system in British markets. This means business. The question has been so thoroughly thrashed out, that it would be tedious to recapitulate here. The only community that benefits by the system are the consumers, and they are not likely to raise a voice against a cheap supply. The British trade, of course suffers, and the opponents are quite right as far as protect against the system.

THE September number of the *Indian Farmer* contains more than the usual amount of matter to be found in this useful periodical. The hint thrown out a short time back that

Indian Forest Officers should contribute more largely to its pages has had a good effect, we see. In the present number we notice the "Brandis Prize for Sylviculture," which has been founded by the great Indian forester to encourage a closer study of the subject. A sum of Rs. 2,000 has been invested in 4 per cent G. P. notes, and the interest on this sum, Rs. 80, "will be given annually for the best English essay on any subject connected with Indian Sylviculture by any past or present regular student of the Dehra Doon Forest School, or of any other Forest School in India. The essays should be clearly written, and should not contain more matter than will fill 20 pages of the size of the *Indian Forester* in ordinary type." Here is a chance for Forestry students to distinguish themselves.

Mr. J. S. GAMBLE, the Conservator of Forests, Northern Division, Madras, has been turning his attention to charcoal-making on an economical scale, and intends carrying out an experiment with a closed iron charcoal-making kiln, manufactured by the firm of Messrs. Bichon & Co., of Paris. With regard to the utility of this kiln, Mr. Gamble says: "So far as can be judged by the account of it, it appears to me to be likely to be very useful, and to save the trouble and damage to the ground which result from the ordinary system, while giving a better outturn and also a considerable quantity of tar. If it proves successful, it will make it possible to utilise the produce of forests now too distant for working, and more especially in the Nilgiris, to make the produce of the Coonoor plantations, for which there is at present very little demand, and where good flat places for ordinary charcoal kilns are very difficult to find, available for the supply of Ootacamund, and even of places in the plains." His proposal has been sanctioned, and an indent has been sent to the India Office for one of these iron kilns. We hope soon to hear more about this experiment.

The *Scientific American* publishes a novel use of toads, which we reproduce: "The latest and most ingenious way of getting rid of cockroaches and water-bugs we have heard of, is related of a citizen of Schenectady whose kitchen was infested with them. A servant, hearing that toads were an antidote, caught three ordinary hop toads, and put them in the kitchen. Not a cockroach or water-bug, it is stated, can now be found in the house. The toads have become domesticated, never wander about the house, and are so cleanly and inoffensive that there is no objection to their presence. Another use for toads is to employ them as insect destroyers in the garden. They are determined enemies of all kinds of snails and slugs, which it is well known can, in a single night, destroy a vast quantity of lettuce, carrots, asparagus, &c. Toads are also kept in vineyards, where they devour during the night millions of insects that escape the pursuit of nocturnal birds, and might commit incalculable havoc on the buds and young shoots of the vine. In Paris toads are an article of merchandise. They are kept in tubs, and sold at the rate of two francs a dozen." Farmers and agriculturists should take note of this.

A little time back, we remember to have read somewhere that long keeping of ensilage destroyed its good qualities. We learn, however, from a home contemporary, that Dr. E. L. Sturtevant has reported the result of an experiment tried at the New York Experiment Station, to determine whether fodder placed in silos, at long intervals, would keep without spoiling. In a small, well-built silo, ten by twelve feet, six tons of cut corn and sorghum fodder were placed during the latter half of August last year, filling it about three feet. It was covered and weighted. A month later it was opened, and a ton and a half of sorghum put in. On the 10th of June, this year, the silo was opened, and with the exception of six inches on the top, the ensilage was found in an excellent state of preservation. By analysis it was found to contain one and a half per cent of lactic acid. A larger mass would probably have given a higher heat by fermentation, and caused the loss. There is no difficulty, as a matter of

course, in partly filling a silo and giving it proper weighting, and adding more afterwards, and again replacing the weight. The silage should not be harmed by the added weight, and the latter condition as the first. In all such experiments the silage should be matured enough to have solid substance. Ensilage has been denounced by some in consequence of cutting it when too soft and juicy.

We have in these columns discussed at some length the system of ensilaging fodder, and have taken a warm interest in the question as a whole from the time it first began to attract attention in this country. It is needless to say that we have followed closely every phase of the question, and have endeavoured to show from theory and practical experience, what we regard as the keystone to the method. But much ignorance prevails; and there is such diversity of opinion as to the real and practical value of ensilage, that it has, from the beginning, been difficult to get at the 'rights' of the matter. That this was felt to be the case even in England, may be gathered from the fact that a Royal Ensilage Commission was appointed to make a thorough enquiry into the subject. The labours of this Commission have now come to an end for the first portion of this year, and we learn that the report containing the evidence taken so far, will be issued at an early date, while the second portion, with the evidence to be collected in autumn, will appear as soon as it can be arranged. Both publications are to be prepared under the direction of Lord Walsingham, the Chairman of the Commission. There will, therefore, soon be abundant matter on which to discuss the benefits of the ensilage system. We hope to receive these reports as soon after publication as possible, and will then give our readers the benefit of all the most important information that may be contained in them.

LORD REAY's public utterances on Indian questions are so far quite worthy of his reputed scholarship, and the good sense which preceded him in this country. We have already noticed his resolution on the inexpediency of curtailing the freedom and discretion of judicial administrators. That resolution is inspired by the true spirit of constitutionalism. Let us now turn to some very wise things which he lately addressed to the Bombay Forest Commission.

"Agricultural problems have always struck me as peculiarly interesting, and the more one looks into the various agricultural systems of various countries, the more one becomes convinced that our legislation in agricultural matters is a mistake, and that in the present condition of agricultural science, which is not by any means so far advanced as it ought to be, we must be careful to interfere as little as possible. Agricultural centralisation would certainly lead to disastrous consequences. To introduce into Lancashire the agricultural system of the lowlands of Scotland or the Ulster custom would betray rashness. Local wants, local customs, and local systems of village tenure have a right not to be wantonly disturbed unless a very good cause be shown for it. In many instances a scientific justification for local agricultural practices unconsciously observed by the population will be forthcoming. I approach agricultural questions with a strong bias in favour of the agriculturist, as every Scotsman would, who has been accustomed in Scotland to give the most respectful considerations to the experience of shrewd farmers and shepherds and farm servants."

What a waste of Indian money would be prevented if the ardour of agricultural reform in our rulers were moderated by such thoughtfulness as breathes in every line of the above extract. —*Indian Echo*.

THE extract from "G. O.," published by the Government of Madras, lays down the programme which it is proposed to carry out in respect to agricultural operations in that Presidency. In the first place, the Saidapet Farm is to be abandoned on its present scale, as a practical failure. It is considered too small for stock-breeding, and its soil is pronounced unsuitable, and "our knowledge of Indian crops too limited as yet for useful experiments." This last is certainly an admission for which we were not prepared. New farms are to be instituted, however, but experiments will, where necessary, be carried

out with the assistance of private agency under the general supervision of the Agricultural Department. This is, of course, as it should be; for, according to Mr. W. Wilson, this Department "is nothing if not practical." Native agriculture, and the analysis of districts will be carefully studied by the Agricultural Reporter, with a view to introduce better methods where they are wanted, but there only. Farther than this, the Government are not at present disposed to go. "To assist the Agricultural Reporter, in investigation, the Government propose eventually to entertain a small body of District Agricultural Inspectors whose salaries will be met from the savings which will accrue from the abolition of the farm. These men will, previous to their entertainment, have undergone a course of training at the Government Agricultural School."

We are somewhat sceptical about the 'savings,' but we may be wrong. The further proposal of the Director of Public Instruction to attach some 30 or 40 acres of land to the Agricultural College as a farm ~~manse~~, as a field for practical demonstration and training for the students of the College, is a good one; and as the necessary details of administration of the Agricultural School, and the course of instruction to be followed therein, are to be considered by the Educational Department, we may hope to see matters placed on a more satisfactory footing than appears to have been the case in reference to the now doomed Salpet Farm.

We extract the following sensible remarks on grazing grounds from the *Civil and Military Gazette*. The subject is deserving of close attention.—"The deficiency of grazing grounds in the North-West Provinces is even more marked than in the Punjab. Several district officers have dwelt upon the desirability of Government interference in this matter in their revenue administration report for the past year. 'One most important measure which might be introduced,' writes the Collector of Shahjehanpore, 'would be to insist, wherever practicable, upon a proper allowance of reserve forest or grazing lands being kept up for each village or group of villages. This would serve three purposes—prevent denudation of forest, starvation of cattle, and perhaps immoderate use of cow-dung for fuel.' In the Hamirpore district, the owners of 14 villages agreed, at the last settlement, to take certain measures for preserving the trees remaining on the waste lands situated within their boundaries; and undertook to pay a higher revenue if they should fail to keep their agreement. Probably a good deal could be done, by means of petty remissions of revenue, to encourage the villagers of the Punjab to plant and preserve trees in this village jungles; but as far as we are aware, little or nothing has been attempted on a large scale in this direction. It is almost needless to repeat that grass cannot be maintained in the plains during a drought, unless it is protected by a fair growth of trees and bushes; and that these, besides serving the above purpose, further afford considerable supplies of those make-shifts for fodder with which the cattle are obliged to be content in such seasons. From the Kumaon district, it is suggested that the preservation of ensilage would be particularly useful there, as green grass is almost unobtainable in April and May in each year." The reference to ensilage is important. It has often been urged that in places subject to severe drought, or where fodder becomes scarce from the scorching effects of 'hot winds,' the remedy is to be found in ensilaging fodder at a time when it is plentiful. The Punjab is particularly subject to hot winds, and so is Rajpootana, Central India, and Sindh. At the first approach of April, the hot winds set in, and fodder becomes scarce. It is, therefore, of importance that during the rains, and the winter months, provision should be made by ensilaging fodder for a 'dry day.'

The following notes of the annual visitation of the Highland and Agricultural Society to their experimental station, which we extract from the *North British Agriculturist*, will doubtless be read with interest here.—Dr. Aitken, along with several members of the Highland and Agricultural Society and others, made the annual visitation of the Society's experimental station at Pumphreston recently. The crop

this year is oats after beans. Owing to the excessive drought, this season the station, in common with many fields under oats, has suffered considerably, so that what is called by farmers tulip rot is somewhat prevalent. The observations drawn from this disease on the station show that where the most liberal application of manures was made, the disease was, at its lowest, while those parts of the station from which manures of a certain kind had been withheld, or only sparsely laid on, were most affected by the disease. The best plots on the station were those to which soluble phosphate had been applied. Amongst undissolved phosphates bone meal was, upon the whole, most effective; but there was little difference between dissolved phosphates from any source. Murate of potash has this year produced a better result than sulphate. Amongst other manures, fish guano, which hitherto has not been prominent, has produced one of the best crops on the station, and nearly free from disease. Dr. Aitken suggested that this was probably due to the residue which had been left in the ground from the manuring of former years, this plot having been noticed to be improving year after year. The plots manured with superphosphates show, as in former years, that it is not advantageous to use phosphates whether too little or too highly dissolved. Considerable discussion took place amongst those present concerning the disease which is so prevalent in the oat crop this year, and it was pretty clearly made out that while drought is mainly the exciting cause, the kind of manures used have some influence, and this matter will, no doubt, be reported upon when the crops are analysed. At the close of the examination, on the motion of Mr. Paterson, of Bankton, a hearty vote of thanks was accorded to Dr. Aitken for the intelligent manner in which he had explained the large and interesting experiments. These tests, he said, were of great importance and of much advantage to agriculturists, and it was satisfactory to see they were carried on in so efficient a manner.

The following circular, dated 10th September 1885, has been issued by the Indian Tea Association regarding the representation of Indian Tea at the London Exhibition of 1886:—

The General Committee of this Association have been requested by the Indian Tea Districts Association of London to bring to the notice of all interested, the arrangements that have been made by them in London as to the Indian Tea Room at the Colonial and Indian Exhibition of 1886, and I am, therefore, directed to give you the following particulars, as supplied by their Secretary:—

It has been arranged that Messrs. Henry S. King and Co., of 85, Cornhill, London, shall take charge of the Indian Tea Room at the Exhibition, under the supervision of a specially-appointed Sub-Committee of five members of the London Association.

The only name which will appear in the Tea Room will be the Indian Tea Districts Association of London and Calcutta.

It is desirable that samples of tea intended for exhibition should be prepared before the end of October, and the London Committee make the suggestion, the adoption of which is, however, optional, that the samples be limited to four kinds or descriptions, say, two of whole and two of broken leaf, as being fairly representative of the entire manufacture of the estate.

Each sample to be not less than 1lb., or larger than 5lbs., and to be packed in lead so as to travel without risk of injury. The samples should be very carefully labelled and sent before the end of December next to Messrs. King, Hamilton and Co., Calcutta, by whom, and at whose expense, they will be despatched to London. Suitable bottles and labels of a uniform kind will be provided in London for the proper display of the samples.

It is suggested that some estates may be willing to furnish neat 5lb. or 10lb. boxes, with the garden name and brand, with the view of attracting the attention of the small trader, as well as the consumer, and for competition with the slightly and attractively little China boxes. These packages can also be sent to Messrs. King, Hamilton and Co., who are prepared to take charge of any photographs, horns, spears, or other articles of interest which may be contributed by planters for the decoration of the Tea Room, and who will undertake to have them mounted in Calcutta and sent home free of expense. Those who attach a special value to any article should signify their desire as to its disposal at the close of the Exhibition.

The total receipts of Indian Guaranteed Railways, from 1st April to 15th August 1885, were Rs. 3,06,06,570, against Rs. 2,93,11,304 in the corresponding period last year; while those of the State lines were respectively Rs. 1,71,19,133 and Rs. 1,48,97,100. The total receipts of Assisted Companies amounted to Rs. 12,84,009 and Rs. 3,38,907, respectively, during the same periods. The railways in Native States show total receipts of Rs. 10,74,776 and Rs. 10,67,622, respectively, during the above-mentioned periods. Turning to estimated expenses, we find that those of Guaranteed and State lines have been included under one head, and were Rs. 3,53,85,703, and Rs. 2,14,78,118, respectively, during the periods noted above. These figures show that the net receipts on both Guaranteed and State lines exceeded the expenditure by Rs. 3,21,03,256 from 1st April to 15th August 1885, and by Rs. 3,03,79,657 during the same period in 1884. Taken at an average, these figures show a decided increase over the receipts of 1884; but, separately, the following Guaranteed lines show a falling off:—

	Rs.
Madras	43,773
South Indian	26,425
Great Indian Peninsula	3,14,495

The following State lines also show a falling off:—

	Rs.
Eastern Bengal	96,512
Nalhatti	5,839
Northern Bengal	26,191
Cawnpore-Achnera	30,108
Wardha Coal	25,657
Nagpore-Chattisgarh	1,445
British Burmah	33,614
Sindia	4,819

The seven Assisted Companies all show a remarkable increase, amounting to Rs. 9,45,102 over the receipts of the previous year. In no instance is there a falling off. Among the lines in Native States, only one shows a decrease, viz., the Bhavnagar-Gondal, amounting to Rs. 1,09,753. Out of the 20 State lines, nine show a decrease, amounting in the aggregate to Rs. 2,24,249. The greatest falling off is shown by the Great Indian Peninsula, viz., Rs. 3,14,495; the aggregate decrease in the receipts of the other two Guaranteed lines amount to Rs. 75,198. The total mean length of Guaranteed lines open during 1885 was 4,133, against 4,025 in 1884, while the State lines were respectively 4,143 and 3,764 miles. The Assisted Companies had respectively 333 and 409 miles open, and the Native States 394 and 358 during the same period, i.e., from 1st April to 15th August 1885 and 1884.

CERTAIN planters of the Nilgiri district have been much exercised with regard to the cheap sale of firewood by Government to the detriment of private enterprise, and have addressed a petition to the Governor of Madras, protesting against the action of certain Government officials in this respect. Their complaint appears to be—

(a) That the Forest Officer of the Nilgiri district takes contracts for the supply of firewood at low rates, lower than have prevailed for 40 years—and that he has taken a contract to supply dry wood at Rs. 6 7 per ton.

(b) That in order to obviate the extinction of the planting enterprise, Government must "prohibit its officers from taking contracts for the supply of firewood, and selling wood to private parties," and confine them to the supply of "Government brick-fields and other kindred requirements."

The Collector of Nilgiris is of opinion that some of the signatories of the petition are engaged in planting firewood trees for sale to the public, but that the majority have only sufficient for their own requirements; and that by the retirement of Government from the field, the price of firewood would be raised so high as to cause serious hardship to the poorer consumers. Looking, therefore, from the consumers' point of view, the participation of Government in this enterprise can only be looked upon with satisfaction. On the other hand, however, the petitioners say that "there is now a considerable amount of wood available for the public," and it may be inferred that if Government enters into competition with them, private enterprise must go to the wall. It further appears that sixteen persons obtained allotments of land aggregating 500

acres in 1869 for fuel plantation, and it is to these grants that the petitioners refer. The Collector, however, points out that the land of fourteen persons, representing 428 acres, has been resumed, in consequence of the grantees having failed to plant it; and that only two persons retain their land to the extent of 77 acres, and that even in these the planting has been imperfectly done. Under these circumstances, the Collector upholds the participation of Government in this enterprise, and denies that the rates have been unduly lowered. To our mind, the petitioners have failed to make out a strong case. If they have neglected to utilise properly the land granted to them, they cannot expect the consumers to submit to pay high rates, when, by Government stepping in, they are enabled to buy firewood at cheaper rates. The Government of Madras have, however, taken a more liberal view, and after consulting the Conservator of Forests, have issued the following order, which should meet the case on both sides:—

The Government observe that large State forests are maintained in this country for reasons of paramount importance to the community. The thinnings and lopplings of these forests must be disposed of somehow, and there does not appear to be any difference in principle between selling such cuttings wholesale and selling them by retail. The Government concur, however, in the opinion expressed by the Conservator that for reasons of departmental convenience, it is desirable to substitute sales on the plantations, if possible, for the existing system. They resolve, therefore, to direct that for the present the system of sale at the Government depot be maintained, with the modification that deliveries at houses should cease, but that after November 1st, the cuttings on plantations and sholas, in compartments to be set apart for the year, be sold by auction in the manner proposed by the Conservator. Should this experiment prove successful the depot will be closed, but a reserve of one thousand tons should still be maintained ready for sale, in case the artificial advantage now to be conferred on certain private growers should result in an undue raising of the price of fuel to the prejudice of the poorer classes. The issue of tickets for head loads to bazaar purchasers will continue as at present.

THE FUTURE OF INDIAN WHEAT.

It has often been said that the tract of country comprising the North-Western Provinces and Oudh is the 'Granary of India.' Judging from the annual trade returns, and the forecasts drawn up by the Director of Agriculture and Commerce, North-Western Provinces and Oudh, there would seem to be a good foundation for this conclusion. On the other hand, the Punjab, where almost the entire native population use wheat-flour as their staple food, may be regarded as the wheat-consuming province of India, and the importance of extended and better wheat cultivation has come to be adequately recognised by the Lieutenant-Governor of the Punjab, who has issued a most important resolution on the subject, in which the whole of the information which has been recently collected regarding the present conditions of the wheat trade of that province, and the suggestions which have been made for its improvement and development, have been gathered together. In taking up the review of a question which so vitally affects Indian interests, it will be as well to note briefly the opinions and suggestions embodied in the resolution under reference. In March 1879, Dr. Forbes Watson, in his report on the subject, considered that India was admirably suited for the growth of the finest qualities of wheat, both soft and hard, and expressed an opinion that the Punjab was probably destined to become the chief wheat-exporting province of Hindostan; and suggested that the cause of the inferior quality of Indian wheats was due to their mixed condition, which might be removed by the introduction of simple screening and winnowing machines. Later on, the question of cheap railway freight came to be considered as an important factor in the export of wheat, if it was intended that it should compete in the home markets with American wheat; and Kurrachi was recognised as the best port of shipment. Its advantages were said to be as follows:—

Situated at the extreme northern end of the Indus Delta, it is connected with the entire river system of the Punjab. It

possesses a harbour safe and easy of approach, with fairly regular soundings, and few formidable currents. It has the additional advantage of being northward of the limit of cyclones. It is less affected by the south-west monsoon than most parts of Western India. Being nearer by 200 miles to Aden, and bringing as it does the great part of the frontier 1,000 miles nearer to England than the route *via* Bombay, the importance of the port of Kurrachi, as an outlet to this province (Punjab) can hardly be exaggerated." This was said at the end of 1882, when wheat was delivered at Kurrachi at Rs. 3.2 per maund. It is now being exported at Rs. 2.7 per maund; and as the sea freight is now 43 per cent lower than it was in 1882, wheat can be delivered in England at 10s. 7d. per quarter less than it could be two years ago, which shows how the Punjab wheat trade has increased. This is further proved by the fact that, in 1879, the export of wheat to Kurrachi was valued at Rs. 74,908; and in 1882-83, exclusive of river traffic, at Rs. 51,42,886; while during the past year it had further increased to Rs. 54,71,950. Although the exports to Bombay have increased from a weight of 218,897 maunds in 1882-83 to 1,435,576 maunds in 1883-84, while those to Calcutta have decreased from 240,032 maunds in 1882-83 to 211,364 maunds in 1883-84, it is considered that there is no reason why Kurrachi should not become the natural and geographical outlet for the Punjab. Hitherto, Kurrachi has engaged but a very small portion of the trade of India, as will be seen from the following figures, which show the proportionate value of the foreign trade of each of the five chief ports during the year 1883-84:—

	Per cent.
Bombay	41.57
Calcutta	38.45
Rangoon	5.07
Madras	5.28
Kurrachi	3.27

During the past year, however, the figures for Kurrachi show a marked increase, amounting to 12.59 per cent of that during 1882-83.

The resolution notices the pamphlet entitled "Punjab Wheat," by Colonel Wace, Commissioner of Settlement and Agriculture, which gives in a succinct manner the actual conditions of wheat production in the Punjab, and which is calculated to prove of real practical value from every point of view. Having seen this pamphlet, we entirely agree in this opinion. Colonel Wace has produced a compilation which, for practical suggestions, and accuracy and clearness of detail, can hardly be equalled.

The Resolution then refers to the disadvantages under which the wheat trade of the Punjab suffers. These, for convenience of discussion, are treated as (1) economical, and (2) administrative and physical. The chief economical drawback is said to be the dirty condition in which the grain is usually purchased; and it is suggested that the first thing is to obtain, if possible, a clear wheat for export, unmixed with dirt and other foreign grain. This is a drawback from which all the provinces suffer, and which is the main cause of the depreciation of Indian wheat in the Home markets. Colonel Wace rightly observes that reforms in this direction can be looked for only very gradually from the cultivators as a body. It is, however, clearly indicated that the agriculturist has at present little or no interest in turning out a clear sack of wheat, as he gets no more from the middleman for the cleaned article, than for the uncleaned. But this is a state of things to be met with all over the country. The only part of India we know of, where a better state of things exists, is the North-Western Provinces and Oudh. Here much care and attention are bestowed upon the production of wheat, free from dirt, and in distinct varieties. The Lieutenant-Governor of the Punjab is correctly informed that these drawbacks obtain to a marked degree only when the cultivator is deeply in debt to the middleman. The middleman, then, is the real obstacle in the production of superior grain; and the only remedy in our opinion seems to be the one suggested in the resolution, etc., that the work of cleaning the grain should fall rather on the trader than on the cultivator; and were enterprising firms to establish depôts of machinery for

cleaning grain, such as that of *Stall Brothers*, referred to in the resolution as having been opened at *Umrkot*, there can be little doubt that, in course of time, cultivators would bring their grain to be cleaned by machinery, which would cost them a mere trifle, and thus obtain better prices. We have heard of some such depôts having been established in the *Bombay Presidency*, which have worked with advantage, not only to the cultivators, but to the proprietors of the machines as well. There is then the question of carriage from the place of production to the place of threshing.

(To be continued.)

LIGHTNING STROKES.

In a recent discussion before the Royal Meteorological Society, it was asserted that meteorologists generally only spoke of lightning *descending* in a careless sort of way, because it was connected with the appearance of clouds which certainly passed over our heads, and that it was always understood that describing a lightning stroke, as coming downwards, was merely the conventional style of speaking. These remarks were elicited from two leading authorities, who observed that any one who gave the subject consideration would come to the conclusion that the discharge was *double*, and that most of the damage done was due to the *upward* stroke. The fact of the matter would appear to be, according to the same sources, that no definite direction can be assigned to a lightning stroke. According to the indications of the electrometer at Kew, the earth was sometimes positive and the air above negative, and *vice versa*. The Superintendent of the New Observatory, who is one—the President of the Society being the other—of the authorities to whom we are indebted for our information, observes on this point: "It did not matter in which way the electric current passed through an object, for the effect was due to the explosive decomposition of the object through which it passes—whether it was water converted into its constituent gases by electrolysis, steam at high pressure, or vaporised metal. Under any circumstances, great force would be generated by the passage of the current." These views are somewhat at variance with hitherto accepted theories. Hence we find Colonel the Hon. Arthur Parnell, late Royal Engineers, in a subsequent paper (read on the same date) before the Society dealing with "The Mechanical Characteristics of Lightning Strokes." The gallant physicist here presents to the scientific world the results of his researches, in regard to the action of terrestrial electricity during the last five years. He says: "Having, as I believe, entered into the special study of lightning phenomena with no preconceived physical conceptions contrary to those generally held, the principal impression that these investigations have left on my mind, up to the present time, is that a lightning stroke is a manifestation of ordinary physical force effected in a highly concentrated form." He then adduces some notes and facts tending to demonstrate the mechanical nature of lightning strokes, and the direction, in regard to the surface of the earth, that is usually taken by them. The value of the results may be gauged from the fact that they are deduced from 1,117 incidents of lightning stroke action extending over a period of 219 years—from January 1665 up to February 1884! The particular conclusion arrived at is—(i). That "lightning" is not a sort of electric fluid that descends from the clouds, injures buildings and persons in the course, and dissipates itself in the earth; but that it is a luminous manifestation of the explosion caused by two equal forces springing towards each other simultaneously from the earth and the under-surface of the inducing cloud, and coalescing, or dying out nearly mid-way between the two plates of the electrical condenser formed by the earth and the cloud. (ii). That of these two forces, it is the earth-springing or upward force alone which injures buildings, persons, or other objects on the earth's surface, and which constitutes tangibly what is rightly known as a "lightning stroke." The first conclusion is confirmed by the observations and experiments of various eminent men, including Franklin in 1752; DeLava, 1764; Adams, 1764; Hare, 1842; Arago, 1835; Ganot, 1835; Tell, 1835; and

later authorities. The second conclusion, re "Upward Strokes," is equally well substantiated. The evidence, relative to the only solitary incident of alleged "down stroke," is sifted and disposed of as probably untrustworthy. The Colonel says, on this head: "That there should be difficulty after careful and close research in obtaining even one single authentic case in history, wherein the action of a downward force has been proved, is in my opinion vindication of the theory that holds these actions to be invariably upward." He has laboratory experiment and electro-static law with him, and, considering that he is opposed to a long popular notion, we are disposed to concede that the records produced demonstrate, with more or less precision, the existence of an upward direction in the force of the stroke.

In India, lightning strokes often produce disastrous results, and are attended with much loss of life. The current year has been prolific in loss of human life by lightning. A great deal of ignorance prevails in regard to the action and tendency of lightning strokes; and the foregoing hints will, we hope, remove some of the popular and generally accepted ideas on the subject, which, we fear, has received too little attention in this country. A proper study of the laws which govern electrical phenomena would show the futility of the so-called lightning conductors, that may be seen rearing their pointed heads above the roofs of our dwelling-houses, churches, and large public buildings.

Miscellaneous Items.

Information has been received from her Majesty's Minister at Teheran, of the notification by the Persian Government of an interdiction, with effect from 11th September, on the exportation of grain from Persian ports.

From Nagpore we learn that 37.13 inches of rain have fallen there, which is about 4 inches above the average, to date. Barar needs more rain for the cotton and *khary* crops. Cholera is rather severe in the Akola district (Barar.)

Efforts have been made within the last year or two in Fiji to acclimatize the tea plant in those islands, and last advices from Levuka and Auckland give very encouraging reports of the tea industry. The tea is described as being of excellent quality.

CAPTAIN B. D. PLUMMER has been appointed Chief Superintendent of Mysore and Nandydroog mines. Owing to the extensive work now being carried on at these mines, a batch of fifteen Italian miners arrived from London last month, and proceeded to the mines.

OWNERS of casuarina plantations, who hitherto supplied the railways in the presidency, not being in a position at present to supply wood, owing to their stocks being exhausted, the Railway Companies find it a difficult matter to procure wood, unless at enhanced rates.

A CORRESPONDENT of nearly 20 years' experience in Japan, who has the interests of the country at heart, writes as follows:—"There is far too much rice cultivation in this country, and it is the cause of infinite mischief to the population; as not only the cultivators, but all in the neighbourhood, have their general physique lowered by the malaria from the fields. Not only the mulberry, but all the European grain and vegetable crops could be grown in these fields, and it seems to me that Government should, by the annual distribution or sale of imported seeds, encourage the people to get out of the old routine and to grow new crops."

THE persistent holding off of the rainfall in the Deccan is beginning to cause anxiety there. With only two or three weeks of the south-west monsoon remaining, barely half the average fall has been reached. Indeed, it is feared that unless the rain comes very shortly, it will come too late to save the greater portion of the dry crops. The *Deccan Times* says that it is just possible that the scarcity anticipated in the Nizam's dominions will, if it occurs, cause that prince to postpone his visit to England. The visit, carried through in a manner befitting his rank, must entail a vast expenditure, which the finances of the State can but ill-afford.

and his Highness is very reluctant to put the country further in debt for a purpose that, however desirable in more prosperous times, is still a luxury which may well stand over.

THE question of providing funds for carrying out the Tanas water-supply scheme was further considered by the Bombay Town Council, when it was resolved to levy a tax on kerosene oil of half an-anna per imperial gallon, which will be equivalent to four annas per case. The daily local consumption is stated to be about 500 cases, and the Municipal Commissioner estimates that the tax will yield an income of about Rs. 40,000 a year. Dr. Peterson was opposed to a tax of something like 8 per cent on an article whose consumption was extensive among the poorer classes of the city, and expressed himself in favour of reducing it by half. But there was a consensus of opinion that a tax of four annas per case could well be borne by this cheap oil, and a proposition to that effect was accordingly carried. No other business of public interest was transacted at the meeting.

THE Indian trade returns for the month of July last continue to show a decrease in the value of merchandise imported; but a slight increase in the value of exports. The total imports during the current official year, up to the 31st July last, show a falling off of nearly 180 lakhs, as compared with the imports for the same period of last year; while the exports have declined by over 186½ lakhs. In the month of July there was an extraordinary falling off in the value of imports into Bengal and Madras, which quite overbalanced the increased imports into Bombay and Kurrachee. Turning to exports, we find that, in the same month, the value of exports from Bombay fell off; but there was a considerable increase in the exports from Bengal, Kurrachee and Birmah. The total value of exports from India during the month amounted to over 533½ lakhs, against less than 501½ lakhs for the same period of 1884.

THE Chamber of Commerce is now circulating a list for signature amongst its members for subscription to the fund being raised by the Planter Association to push Ceylon tea in London during the Colonial and India Exhibition, which we hope to see supported liberally by everyone. Another list, to be circulated amongst those who are not members of the Chamber and the general community in Colombo, is just being started, and it also should receive universal support from every class and interest in the island without any exception. There is no possible manner in which the public as colonists can better further the interests of the island than in subscribing to this fund. It is the cheapest possible advertisement they can get, and we shall be terribly disappointed if much more than the sum named by us is not forthcoming. Lists are also being circulated by the Secretary of the Handy Planters' Association throughout the planting districts.

Selections.

EXTRACTS FROM THE PROCEEDINGS OF THE AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.—DATED AUGUST 20, 1885.

ORANGE CULTIVATION IN INDIA.

From Dr. E. Bonavia:—

"I am endeavouring to unravel the different kinds of oranges and lemons known in India, and to find out all about them. Can you or any other member of your Society help me in the following:—Calcutta is supplied with the Sylhet orange. What do natives in Sylhet call that kind? Does it grow wild, that is, self-sown, without any cultivation, or is it planted regularly and cultivated, or both? Does it belong to the Simlana variety or to the Keosika variety? Are there any other varieties of orange or lemon or lime belonging to Sylhet, besides the one sent to Calcutta? If so, what are their names? Is the trade in Sylhet oranges extensive? Can you give me any idea of its annual extent in rupees, or boat-loads, &c.? Are Sylhet oranges ever washed down by floods into the rivers, and do they float? Perhaps you may have some members in Sylhet, who could kindly give me the information."

"If you make known to your members that you have the Malta lemon, you might disseminate it readily."

A copy of this Society's Journal, Vol. I, No. IV, New Series, containing an account of a visit to the Orange Groves of Shalla,

by Mr. Brownlow, was sent to Dr. Bonavia, who again wrote on the subject as follows :—

"I have to thank you for so kindly sending me the volume containing an account of the 'Orange Groves of Shalla.' It is exactly what I wanted, only it was written in 1869. To save you trouble I will write directly to any one in Sylhet, who can give me a little more recent information; if you know any one, his address will oblige. Lime is a large constituent of the orange tree wood, and I fancy Mr. Waldie did not get a 'typical sample of soil, or only a sample of surface soil.' One of the exports is limestone, and it is hardly possible that in a region where limestone rock is so plentiful, that the detritus should not reach the alluvium in larger proportions. Do you know any other part of India beyond Sylhet and Nagpore where oranges are largely grown? Have you any account of the Nagpore (Satpura range) Orange Groves in any of your journals? The Orange merchants in Calcutta will be able to inform you about how many 'Sons' (3,000 oranges) reach the capital in a season or perhaps how many boat-loads. Are they sent now by country boats or by steamer. I have a notion than the Mandarin orange, considered so choice in the Mediterranean, would do well in Sylhet. Have you got it in your Calcutta garden? If not you can get it either from me or Lucknow; the Malta egg, and blood, and common round, ought to do there also, could not you get them to try them? The Malta egg and blood, orange, are exquisite, and have not a very thin skin and therefore would travel well to the capital. It is my firm belief that the fruit trade of India is capable of great expansion with benefit to every one."

Some members have been addressed on the subject and with their sanction, Dr. Bonavia will be put into communication with them. Any information as to the disposal of members will be welcome.

SILK.

From Mr. Natalis Rodot, Paris, Honorary Member, who writes to the President of the Society as follows :—"I have the honor to have been for the last 3 years an Honorary Member of the Society."

"I have just completed the first part of a work on the silk industry, which I wrote by the invitation of the Minister of Commerce of France. The first volume just issued, will be kindly handed to you by H. E. the Viceroy, and I beg you will present it to the Society on my behalf."

"The first volume is regarding the domesticated silkworm, and the second will refer to the semi-domesticated and wild silks, and will be finished during the year. I of course mention in this volume the Indian silkworm, and have done my best to state their condition."

From Mr. E. A. Manuel, Rangoon, forwarding a paper on the Silks of Burma. Acknowledged with best thanks, and transferred to Journal, Vol. VII, Part IV.

CULTIVATION OF THE PATNA ONION.

An application was received from the Secretary of the Eurasian and Anglo-Indian Association, Royapetta, for seeds or bulbs of the Patna Onion of the large white-skinned variety. In the letter the Secretary says :—"I may mention that the Association has successfully established a Colony in a most favourable locality for the benefit of Eurasians and domiciled Europeans, where a number of families have been already settled in the pursuit of rural occupations. Among the settlers are men of education and intelligence, and it is one of the aims of the Association to place within their reach the means of entering into new enterprises."

Mr. W. B. Careshore, a Member of the Society, was communicated with on the subject, and gives the following information as to the cultivation of Onion in the South of the Tirhoot District :—"I think I can get you some Onion seed now, it is sown in February and when about 8 inches high, transplanted into convenient plots for irrigation; these plants die down in June, when they are taken up. Those who require Onion seed, plant out the bulbs in August, and the seed will be ready in May and June, at about the same time as the new crop sown in February."

CEARA RUBBER.

Messrs. Begg, Dunlop and Co. applied for information regarding the Ceara Rubber for a correspondent enclosing the following extract :—

Extract of a letter from a Terni Tea Planter, dated 3rd August 1885.

"As far back as April last, I wrote you asking for information regarding the growing of Ceara Rubber; you very kindly sent me a printed paper by J. F. William Brothers, Ceylon, on the subject

and quoted price of seed, &c. Now for the last two years, I have been planting rubber in different places as an experiment, and have now got some trees over 11 feet high and 7 inches and more in girth, a foot from the ground, they are by no means weak, nor are they wanting in milk, i.e., rubber; the least scratch causes it to rush out of the tree. I am convinced that this rubber, not only grows and thrives as a tree in this district, but that it would give a very large yield of dry rubber."

"What I write you about now is, can you inform me positively how much does it yield in its 5th, 6th, and 7th seasons, and what has its produce been sold for per lb., in London, or any other market."

The following reply was sent :—

"The planting and cultivation of Ceara Rubber are in such an early stage that sufficient data is not available, to admit of your enquiries being answered fully."

"From the extract from your Manager's letter, I should imagine the trees, he mentions, are as yet too young to be tapped profitably; as they are only 7 inches in circumference at a foot from the ground, they can hardly bear more than two years' growth; probably five or six years would be the earliest at which they should be worked."

Mr. Cross, a great authority, says, in a letter to the *Tropical Agriculturist* (November 1st 1884),—"The plants should be allowed to attain a good size before being operated on, they will then bear to be tapped or milked every day for nine months of the year. If the wood is not much injured in this operation, they will bear working for 20 or 30 years."

In Mr. Robert Cross's account of his discovery of the Ceara Rubber tree, he mentions the largest trees he saw tapped were some 50 feet in height, with trunks 9 inch to a foot in diameter. So it would appear either that the tree, when tapped, is not very long-lived, or that the climate of Ceylon is more suitable for its development. Dr. Trimen in his administration report of the Royal Botanical Garden, Ceylon for 1894, mentions having cut down a Ceara Rubber tree, of nearly eight years' growth, that was 14 inches in diameter. As the plant was only discovered in 1876, this is one of the oldest of the trees of which a record has been kept. Dr. Trimen alludes to it as one of the original plants and says :—"This tree was thoroughly drained in 1882, but on now repeating the operation nearly 1½ lb. of dry rubber was obtained." This answers your Manager's query, as to what is the yield in the 8th season, and although this is not enough for calculation, is the only data we have. Messrs. J. P. Williams and Brothers of Henderagoda, Ceylon, in one of their recent circulars, state as follows :—

"We have tapped a Ceara Rubber tree of six years' age at the beginning of April; three days' successive tapping, with an ordinary knife, gave 8½ oz. of dry rubber." The operation can be done twice a year. They further state that Ceylon Rubber has been valued in London at 3 to 4 shillings a pound.

ACCLIMATIZED MAIZE.

Messrs. Lloyd & Co. exhibited some fine samples of maize grown in the Terai. These cobs were grown from the seed of last year's crops, which again was the product of Australian seed. The cobs, as regards size of grain, bear comparison with the American Maize imported by the Society for seed, but are not so regular. The standard, however, is very high, as the American Maize in question is especially grown and cultivated for seed. Messrs. Lloyd & Co.'s experiments prove that a very superior class indeed of seed Maize can be grown in the Terai, the distribution of which in various parts of India would have a marked effect on the quality of this staple. The following are extracts from their Manager's letters on the subject :—

From Mr. Monypenny :—"I am sending you to-day by post a parcel containing cobs of Australian corn. These may be of some interest as they are from the third sowing. The cobs are not quite so large as those grown last year, but I do not think the grain has degenerated much. I hope shortly to send you some grown by natives. I have been shown some very good ones, but they are not yet ripe. As far as I am able to judge, the introduction of the Australian corn is a complete success, and likely to prove of great benefit to the natives." And in a later letter, he says :—

"I am to-day sending you by parcel post two cobs of Maize grown by natives in the service of the Company. The largest of the two is the finest I have yet seen, and hence anything I have been able to grow myself. It is some satisfaction in distributing the seed when they are able to grow such produce as this." *General Terai Tea Company.* Extract from Mr. A. Curry's letter, dated 13th August 1885 :—"The corn you are sending me from the United States is too late for sowing this year, as

* An analysis by Dr. Waldie of Soil from the Orange grove, is given in Mr. Brownlow's paper.

May is the month in the Terai, it has not arrived yet, but when it does, I shall have it carefully dried and put into bottles for next year. The four cobs I sent you from this year's crops were partly grown on the same land as last year, and partly on new, and the only cultivation I gave it was that I thoroughly cleaned the land first for sowing and then hand-weeded it twice; nothing more was done to it."

Messrs. Lloyd & Co., are to be congratulated on the success of their experiment, and their coolies, no doubt, fully appreciate the fine quality of the seed thus placed at their disposal.

THE FRENCH OPEN-AIR SILO.

Manson has several times been made in the *Review* of the latest French idea in ensilage, that of simply building up the material in the open air and weighting it. A correspondent of a French agricultural journal describes his method of making a stack silo of green corn which we consider of sufficient interest to condense for our readers. Beams or sills are laid upon the ground at about a distance of two feet from each other, their length being according to the desired width of the silo and the number of beams according to the length desired. Each of these has a mortice near the end to receive the bottom of uprights, which pass through far enough to admit of an iron pin through a hole under the beam or sill. The corn fodder was laid crosswise on these beams, and built up as solidly as possible till the mass is built up. Boards are then laid on the top, uprights are placed in position in the mortices in the sills and secured by the pin underneath. A second set of beams morticed like the bottom ones are slipped over the top of the uprights which have holes for quite a distance down from the top for inserting a pin above the top beams. This, as will be seen, gives the mass of green fodder inside of the framework of sills, uprights and overhead beams. The pressure was produced by the common lifting jack, a pin through the top of the upright, forming one point of support and the top of the beam the other. As the jack is worked, the beam is pressed down upon the mass: when sufficient pressure is produced it is held in place by a pin slipped through a hole in the upright. Each beam on a side is treated in this manner, and then the opposite ends, bringing them down to a level. Pressure was applied in this manner daily for eighteen days, after that time only once a week. The ensilage was removed in sections, taking off one beam at a time and cutting down, leaving the pressure upon all the rest of the mass. The ensilage came out in a perfect state of preservation, with the exception of three or four inches around the sides which was black and mouldy. The silo thus described was a small one holding but 2½ tons. But the principle is just as applicable to larger masses, provided the requisite pressure can be obtained. Some improvements upon the above described plan suggest themselves, which we give: First, we would put the uprights in place before beginning to build the mass, staying them across the top to keep them at the proper distances, or the top beams could be slipped over the ends and held in place by a pin, the uprights being stayed to keep them in a perpendicular position. Then place boards inside the uprights, which would enable the packing of the outside much more solid than could otherwise be done. These boards could remain in place or be raised up as the filling proceeds, as in building a concrete wall. No mention is made of filling in with earth between the sills, but this should be done so as to leave no air space below. In regard to width of silo, for obvious reasons it should not be made very wide, not to exceed 6 feet, as a narrow one is more easily compressed than a wider one. No mention is made of the size of the timbers used for sills, uprights and beams. For the sills and beams they should not be less than 6 x 6 inches, and for uprights 2 x 4, though possibly 2 x 4 would answer. The hole in the bottom of the latter should be at least six inches from the end, and large enough to take a five-eighths or three-quarter inch iron pin. It would be well to put a three-eighths iron bolt through the bottom flange to strengthen it, as the strain upon it will be very great. From the description above given any farmer who wishes to experiment this fall on the French plan of an open-air silo at but little expense. The lifting jack or two of them would be essential for securing the pressure unless he can devise some other plan equally efficient for producing it. The success depends upon a sufficient amount of pressure being brought upon the mass. This might, perhaps, be obtained by the use of a chain and lever, a loop in one end of the chain being slipped around the end of the sill, and the other over the end of a lever, working over the top of the upright beam, the pressure gained being secured by inserting the pin in the bottom of the upright, as the beam is forced

down, and new purchase obtained by shortening the chain. With a sill not more than four feet wide, a leverage so worked might secure all the pressure needed. We do not assert that the result of such experiment would be entirely satisfactory, but it is one of those cases where the injunction of the apostle to the Gentiles is applicable: "Prove all things, hold fast to that which is good."—*Farmer's Review*.

GIGANTIC FLOWERS.

Certain localities seem particularly adapted for the development of both animals and plants, and in the region including India, the islands of the Indian Archipelago, and outlying Australia, certain forms of the latter are found, that in the size of their fruit and flowers, excite the greatest wonder in those who have beheld them, and not a little incredulity in those who have not been so fortunate. In the southern continent of our own hemisphere is found the great lily *Victoria regia*, that created the sensation of the time when discovered. The *Victoria regia*, however, is dwarfed by several flowers that have since been discovered, and, indeed, in South America there are one or two that equal, if not exceed it. The most wonderful discovery in plant life in recent times is a gigantic drum. It was found by Beccari in Sumatra, and the plant, which has been named *Amorpha phallus titanum*, has an ally in northern countries in the little "wake robin" common to English hedgerows. The Sumatra arum is a wake robin of mammoth proportions, and it is said that the first European that observed it at first refused to believe that it was a flower. This was before the time of Beccari, who brought the plant before the scientific world. A party was travelling through Sumatra with native guides, when one of the latter brought into camp a huge object of evidently vegetable structure, at least six feet in length, and endeavoured to make the white men believe that it was a flower, or part of one. The story, however, was not credited, and was forgotten until the real discovery was made by the Italian botanist mentioned. He found the plant growing in secluded parts of the country, and considered it to be a most remarkable example of vegetable growth. Imagine, if you can, a tuber five feet, and sometimes more in circumference; from this growing leaves on foot stalks, ten feet in length, divided and torn by the wind, yet covering an area of forty-five or fifty feet in circumference. Above this towered the gigantic flower, impressing the beholder not only with its size, but by its peculiar colouring. The central column or spadix, that in the wake robin is used as a button-hole bouquet, is in this tropical cousin, six feet in height and proportionally stout. The spadix from which this rose was about three feet in diameter, of a bell shape, the edges richly crumpled and toothed in a fantastic manner, and coloured a pale greenish tint upon the inside and a rich, black metallic purple without. A group of these plants would present a remarkable sight, their enormous leaves, the large masses of colour and the huge waving central column resembling more the creatures of some vivid imagination than the reality. If we consider diameter, the discovery of Sir Stamford Raffles in the same country is indeed a greater marvel. The plant now known as the *Rafflesia arnoldi* is an enormous parasite uncouth and fleshy, seemingly attaining its huge dimension by literally absorbing the juices of its neighbours. It is invariably found growing upon the roots of other plants, leafless, rootless itself, represented only by the gigantic flower, from which rises an odour sickening and foetid in the extreme. The plant first observed was considered an enormous fungus or agaric, but it was soon shown to be a flower. Imagine a rose blasted and swollen, weighing fifteen or twenty pounds, its petals reduced to five in number, the thickness of each being over an inch, each one measuring a foot from the base to the apex, and some idea can be gained of this monstrosity of plants. It measured over three feet across the surface, and the neotary, a vessel capable of holding six quarts, was filled with a reeking fluid, that gave out an odour like tainted beef, and was a trap, containing the bodies of myriads of insect victims. The flower was first discovered on the Manna River, Sumatra, where it is known as the "Devil's Sign Box," and is calculated to create a decided impression on the mind of the observer. Dr. Arnold, after whom it is also named, says of the effect it had upon him when coming suddenly upon it—"To tell the truth, had I been alone, and had there been no witnesses, I should, I think, have been fearful of mentioning the dimensions of this flower, so much does it exceed every flower that I have ever seen or heard of." In the island of Java another of these giants has been found, differing but little specifically, and being nearly as large as the Sumatran ally.—*Scientific American*.

FARMING IN AMERICA.

THE annual report of the American Department of Agriculture, just issued, has its special feature of interest in a very able paper entitled 'Agricultural Graphics,' by the Hon. J. R. Dodge, the famous statistician. It is thought with facts and figures which cannot fail to interest people in this country, and especially the landowning and farming classes. Mr. Dodge's pictures of American farming not only show American themselves the progress they are making, but they show us also how it comes to pass that our English markets can be filled with American goods to the disadvantage of our own farmers, but to the advantage of our large and thick population. The facts given are instructive and curious.

It is curious to know, for instance, that the land surface of the United States makes an aggregate of 1,859,108,800 acres, exclusive of Indian territory and Alaska. Of this area 536,081,835 acres are in farms. The farm area of the United States has nearly doubled in thirty years, increasing from 293,560,614 to 536,081,835 acres. During the first ten years the taking up of Government lands in the west and south and the State lands of Texas was active. The most fertile areas, little encroached upon in the newer settlements, were taken possession of with a certainty of appreciation in value that added intensity to the pursuits of homes obtainable at insignificant prices. The absolutely free homestead had not at that time been guaranteed by law. In the next decade the disturbing element of civil war prevented aggregate increase, the States within the theatre of actual warfare declining in area, some farms being abandoned and hence not counted as farms. At the same time many of the Western States showed a considerable increase—Kansas, for instance, with 1,773,400 acres in 1860, had 5,656,879 in 1870. Between 1870 and 1880 the new lands taken into the farm area exceed 1,128,000,000 acres. Of this, no less than 49,000,000 were in divisions between the Mississippi and the Rocky Mountains. The increase was large in the south, especially in Texas, where it was nearly 18,000,000. The proportion of unimproved land, notwithstanding the new land taken up, has been constantly decreasing. It was 61.5 per cent in 1850, 59.9 in 1860, 53.7 in 1870, and 46.2 in 1880. The aggregates are:—

Years.	Farm Land.	Improved Land.
1850	293,560,614	113,032,614
1860	407,212,528	163,110,720
1870	407,735,041	188,921,009
1880	536,081,835	284,771,042

A very curious fact in relation to other industries is also shown, and this is the values in agriculture are everywhere enhanced by the increase of the non-agricultural populations. Thus, where the agricultural population is 77 per cent of the whole, farms are only worth 5 dol. 18 cents per acre; where it is 58 per cent, farms are worth 12 dol. 53 cents per acre; where it is 42 per cent 30 dol. 55 cents per acre; and where only 18 per cent they go up to 38 dol. 55 cents per acre. Of course this was a result only to be expected, but still the figures put the subject in a very pertinent and striking manner. The above figures are averages for groups of States, but it may be added that values of farms are as low as 4 dol. 19 cents per acre in Alabama, where there is an agricultural population of 77 per cent, and as high as 200 dol. 15 cents per acre in the district of Columbia, where only 2 per cent of the population are engaged in agriculture.

Similar influences are at work also in reference to wages for agricultural labourers, and these wages per month are given. As this is a matter of great interest to those who may be thinking of leaving this country for the United States, we give these wages for 1879 and 1882:—

Group of States.	1879.				1882.			
	\$ c.	d.	s.	d.	\$ c.	d.	s.	d.
California	41	0	8	4	38	25	7	15
Eastern States	20	21	4	0	26	61	5	8
Middle States	19	69	3	18	22	24	4	10
Western States	20	34	4	1	23	63	4	14
Southern States	26	81	2	13	15	30	3	1

In this table the dollar is turned into English money at 1s. to the dollar and a half penny to the cent.

The total value of farm animals is shown to be 2,467,859,924 dol., and of this 44.6 per cent represents that of cattle, 23.5

per cent of horses, 10 per cent of swine, 5.5 per cent of mules; and 4.9 per cent of sheep.

Other diagrams deal with the wheat industry, and one of these shows that the principal wheat region of the country is the Ohio Valley, and not the North-West or the Pacific States. This is a fact not generally appreciated. The difference in rate of yield of the States and Territories in 1879 is shown. The Ohio Valley makes the largest yields, New England about the same as the Pacific coast, and the spring-wheat region much less. The average rate of yield is small in the south, though there are instances of very heavy yields, indicating the possibilities of certain soils in that region from wheat production:—

States.	Yield per Acre. Bushels.	States.	Yield per Acre. Bushels.
Maine	15.2	Texas	6.3
New Hampshire	15.6	Arkansas	6.2
Vermont	16.3	Tennessee	6.1
Massachusetts	16.4	West Virginia	10.9
Rhode Island	14.1	Kentucky	9.8
Connecticut	17.6	Ohio	16.0
New York	15.7	Michigan	19.5
New Jersey	12.7	Indiana	18.0
Pennsylvania	13.5	Illinois	15.8
Delaware	13.4	Wisconsin	12.6
Maryland	14.1	Minnesota	11.4
Virginia	8.7	Iowa	10.2
North Carolina	5.2	Missouri	12.0
South Carolina	5.6	Kansas	9.3
Georgia	6.6	Nebraska	9.4
Florida	5.2	California	22.0
Alabama	5.7	Oregon	15.8
Mississippi	5.0	Nevada	16.8
Louisiana	3.4	Colorado	18.9

The production of wheat per head shows also some curious facts. In Louisiana this is little more than half a pint, while in Minnesota it goes up to no less than 44 bushels. On this subject some most instructive statistics are given, comparing the figures for the United States with those for European countries. On this subject Mr. Dodge says:—Russia, the principal competitor of this country in wheat exportation, has only 2.1 bushels per head, while the United States had 9.2 in 1879, the census year. The reason is Russia exports wheat and eats but little of it, using rye instead. Germany has the same relative supply, and she uses rye rather than wheat for bread. Hungary, France, and Spain stand in the front rank as to supply per head. The following table shows the quantity produced, the population, and rate of supply in the States of Europe:—

Countries.	Wheat. Bushels.	Per head.	Population.
Austria	44,543,126	2.0	22,316,507
Hungary	131,746,878	8.4	15,642,102
Bolivia	24,900,030	4.5	5,535,846
Denmark	3,102,821	1.5	2,018,432
France	294,400,346	7.8	37,672,048
Germany	83,823,048	2.1	45,213,297
Great Britain	82,265,783	2.7	30,189,220
Ireland	3,674,155	0.8	5,697,730
Greece	4,370,649	2.8	1,560,800
Italy	155,012,168	6.4	23,459,451
Netherlands	5,439,533	1.3	4,172,971
Portugal	7,579,088	1.0	3,906,183
Roumania	25,000,000	4.7	5,376,000
Russia	171,389,866	2.1	81,660,349
Serbia	4,066,720	3.3	1,259,000
Spain	117,563,372	7.3	16,000,000
Sweden	3,106,779	0.7	4,579,115
Norway	234,703	0.2	1,518,853
Switzerland	2,145,828	0.8	2,693,129
Turkey	40,867,200	4.2	9,800,000
Total for Europe	1,215,809,793	3.7	327,020,132
Total for U. S.	559,453,187	9.2	50,154,758

A most interesting series of diagrams is also given showing the production of maize, which proves that this is the staple of wheat, though the exports are not so large. Thus in 1882 the production of maize amounted to 1,531,000,000 bushels, of which

SKINNY MEN.

"Wells Health Renewer" restores health and vigor, cures Dyspepsia, Impotency, Debility,
A. W. Mason & Co., Chicago, Sole Agents.

40,338,000 were exported. Of wheat 421,086,180 bushels were grown, and of these 111,524,182 bushels were exported. Of all cereals the following are the productions and exportations—

	Production.	Exports.
	Bushels.	Bushels.
Wheat	1,754,591,676	49,572,329
Oats	459,483,137	180,304,150
Barley	407,858,939	780,306
Rye	43,097,495	1,123,921
Buck wheat	19,891,595	2,990,109
	11,917,327	

The year for which these figures are given is not stated. The production of all cereals per head of the population is given for Europe and the United States. The European average is 16 1 bushels per head; that of the United States amounts to as much as 53 8 bushels. In Great Britain it is 9 5 bushels per head. The use of corn in America in place of roots and forage crops in the feeding of farm animals makes the disparity less than it appears; but even making allowance for this, the figures show that that country has an unprecedented supply for the sustenance of man and beast—*North British Agriculturist*.

IMPORTANCE OF INSECTS, ESPECIALLY BEES, TO FRUIT PRODUCTION.

THE following extract from an address on this subject by Frank R. Cheshire, of South Kensington, London, England, will be read with much interest and profit by all fruit growers—

"Blooms are produced by plants in order that seeds may follow, and so the race be continued. Two parts are essential to this reproduction—the anther and the pistil, the latter very generally occupying the central position. The anther is usually a double-celled pouch, the contents of which by segmentation breaks up into a number of perfectly similar parts called pollen grains, which, though minute, are complex in structure. When these are mature, the anther splits or dehisces, and the pollen escapes, but it needs in some way to be applied to the termination of the pistil called the stigma. When this application is effected, the pollen grains absorb moisture, its interior portion swells, and actually throws out a tube, which often grows to a great length in making its way towards the unimpregnated nucleus of the ovule which is situated in the vary at the base of the pistil. In this nucleus a large cavity filled with protoplasm has developed called the mother cell, within which we find the embryonal vesicle to which the contents of the pollen grain is transferred by the channel of the pollen tube. This is fertilization, and upon it depends the production of seed, for the new individual plant has its beginnings from this interfusion.

"An examination of most blooms will show that the essential organs before referred to are so placed that an accidental or unaided transfer of pollen to stigma is unlikely, and where this arrangement of parts is not found, it frequently occurs that the anthers ripen and dehiscence much before, or not until some time after the stigma has so matured as to be ready for pollination. In the former case, as we may observe in the common garden, *Nasturtium* (*Proximum majus*), the pollen is all carried away by insects by the time the stigma presents itself, so that if fertilization be effected, it must be through the bringing of pollen from other blooms still shedding it. Insects are the means which accomplish this, and to secure their visits, the blooms spread them a banquet.

"The apple is called by the botanist a pseudo-sycarpous fruit, because it may be regarded as five fruits gathered into a unit by an envelope formed by a development of the calyx. If an apple be cut across, we see five compartments or dissepiments in the core, each one of which should contain pipe or seeds. The bloom which preceded the fruit had five stigmas, each one of which was complicated with a dissepiment and required an independent fertilization. Bees seeking honey would by getting their breasts (fringed as they are with abundance of long webbed hairs), thoroughly coated with apple pollen, and sitting to a bloom whose stigma had reached the receptive condition, bring about fertilization. It would, however, frequently happen that three or four of the stigmas only would be pollinated. In this case an apple, though an imperfect one, would be produced. Bees, attracted by the sight, frequently drop a quantity of their pollen, hence known as windfalls, but the actual cause of this dropping is in by far the largest number of instances defective fertilization.

"In an examination made some time since of a large number of windfalls, less than 1 per cent were found to have fallen through injuries traceable to insect pests, while the remainder had received pollination in from one to four dissepiments only.

"Fertilization is followed by a determination of nutrition towards the seeds, and the parenchyma of the apple as a protective envelope gathers around them. If, therefore, we cut a defective fertilized apple across the middle, we find a hollow shrunken side lying over the unfertilized portion of the core. These facts taken together, show conclusively how completely our apple crop is dependent upon insect agency, and amongst these the hive bee takes the most important place.

"In the case of the strawberry, the parts popularly denominated seeds, which crowd its surface are really the fruits technically called achenia, while the strawberry itself is really a succulent development from the flower stalk. The stigma each of the achenia carries must be fertilized by insects which are attracted by the honey secreted by a ring of glands situated at the base of the strawberry. The anthers are wide set, and as the insect walks around the bloom applying its tongue to the circle of glands, one side of its body is dusted with pollen from the anthers, while the other is applied to the stigmatic faces. In passing from bloom to bloom, it frequently reverses the order of its progression, sometimes going around, by turning to the right, and sometimes to the left, as a result the pollen gathered upon one side of the body is probably transferred to the stigma of the next flower visited. As in the case of the apple so here, fertilization determines nutrition. The placenta of the fertilized achenia increases enormously, the strawberry grows and matures, but where any of the stigmas escape impregnation, there the strawberry remains without growth, while the other parts are rapidly increasing around it. (Is not this the cause of knotty berries?)—*Ed. N. R.* The examination of a few fruits would be sure to supply examples where in circumscribed spots, no progress has been made since the first full expansion of the bloom. The achenia are close set and green, and the flesh of the strawberry is there crude and hard, while the rest is sweet, soft, and luscious. Imperfect insect work is again the explanation. Bringing before us the remarkable fact that no perfect strawberry can be produced without, perhaps, from three to four hundred independent fertilizations, accomplished, it may be, by the hive bee, which, in filling the niche in which the Great Creator has placed it, in unceasingly laboring in providing for the wants of its younger sisters, is unconsciously supplying to its master not honey only, but honey and fruit.

"The raspberry, although of another type, somewhat resembles the strawberry in the multiplicity of its stigmas (60 or 70 to each bloom), the wide setting of its whorls (about 80 or 90 in number) and its circle of honey glands. Similarly, too, the insect visitor in seeking nectar, passes between the anthers and stigmas, applying its right side to one and its left side to the other. Each seed fertilized by these visits is soon surrounded by a luscious envelope which protects the seed from injury and makes the manufacture of raspberry jam a possibility. These rounded red masses, with their enclosed seeds, technically called drupelets, and never formed unless fertilization has taken place, neither ripening or growing being possible in its absence. We see, then, in an aspect which may be new to many of us, that this wondrous scheme of nature has correlations which we never could have anticipated; that a large part of the insect world is complementary to plant life, and plants in turn the sustainers of these insects, and that man, although he can plant his trees, is in no small measure dependent for a crop upon the assistance of those little laborers, which, by their unconquerable industry, supplied his table with sweets for long ages before he discovered the use of the sugar cane."—*Farmer's Review*.

THE VALUE OF SULPHATE OF AMMONIA AS A MANURE.

By Mr. F. J. Lloyd, F.C.S., Lecturer on Agriculture at King's College, &c, London.

Writing to the *Journal of Gas Lighting*, Mr. Lloyd, F.C.S., says:—of late the *Journal* has contained some interesting matter in reference to sulphate of ammonia. Perhaps, therefore, a few words on this subject from an agricultural point of view might not only prove of interest to its readers, but, while dispelling from their minds the false views regarding the nature of this product, enable them to rightly estimate the true relative merits of nitrate of soda and sulphate of ammonia as manures. Each of these substances has a manurial value; and both owe this value to the same fact—viz., that they contain nitrogen. In the one the

nitrogen exists combined with hydrogen as ammonia; in the other, combined with oxygen as nitric acid. It is a well-known fact that 100 parts of commercial sulphate of ammonia, of 94 refraction, such as is now usually sold for manurial purposes, contains about 20 parts or more of nitrogen; while the detrimental impurities, the various cyanides, which used twelve or more years ago to be somewhat prevalent in sulphates of ammonia, are now seldom met with. On the other hand, commercial nitrate of soda, of 95 refraction, contains little less than 16 parts of nitrogen. Hence, unless it can be shown that the nitrogen in sulphate of ammonia is less valuable to the farmer than the nitrogen in nitrate of soda, it is evident that, so long as a ton of nitrate of soda can be bought for £10 (which is approximately its present price), sulphate of ammonia is worth £12-10s. a ton. Now, is the nitrogen of ammonia as valuable to the farmer as the nitrogen of nitrate? In order to answer this question, which lies at the root of the whole subject, it is necessary to briefly state some facts regarding the function of the roots of the plant, and the properties of the soil. The majority of plants take most, if not all, their nitrogen from the soil as nitric acid. There can be no doubt, therefore, that nitrate of soda will act upon vegetation more rapidly than sulphate of ammonia. But it is equally certain that every properly cultivated soil possesses to a high degree the power of nitrification—that is, it converts all nitrogenous substances gradually into nitric acid. Ammonia is one of the substances most easily so converted. Hence it is certain that, when sulphate of ammonia is used as a manure, the soil will gradually convert the ammonia into nitric acid, and supply to the plant nitrogen really in the very same form as is supplied by nitrate of soda. So far it is evident, then, that nitrate of soda is only more beneficial than sulphate of ammonia, inasmuch as it acts upon vegetation more rapidly.

Next let us consider the action of the soil on these two substances respectively. The late Dr Voelcker, among his valuable additions to agricultural chemistry, left none more valuable than his researches upon the action of soils on manures. By analysing the water flowing from the drains of large fields, where crops were cultivated under varying conditions and manures, he proved that nitrate of soda is washed rapidly through the soil by rain, so that a large quantity of the nitrogen so applied to the soil is never taken up by the roots of the plants; and during the time there is no crop growing, the nitrate of soda is being merely washed away. Not so with sulphate of ammonia. Only once or twice, in all his experiments, did he find ammonia being washed through the soil into the drains, and then only in minute quantities, and this was found to be the case even where the land had been manured with 4 or 5 cwt. of sulphate of ammonia—far larger quantities than are usually employed. What, then, became of the ammonia? It was found that all fertile soils had the power of retaining ammonia, which became only gradually converted into nitric acid; and then only, and not until then, was it washed out of the soil. Meanwhile, any plant growing in the soil, would be well able to take up the nitric acid as it was formed, so that less would be lost, than where the nitrogen had been applied as nitrate of soda. If, then, nitrate of soda is more active than sulphate of ammonia, still the latter is more lasting and less wasteful. It is evident that manure manufacturers are well aware of this fact, for one seldom finds nitrate of soda admixed in compound manures, except for special and forcing purposes, while sulphate of ammonia is largely and rightly used for mixing with phosphatic manures. If I have made my meaning clear, it will be evident that the producers of sulphate of ammonia have nothing to fear, from theoretical reasons, as to the supposed inferiority of this manure, when compared with nitrate of soda.

As might be anticipated, practice in the field confirms these scientific conclusions. Thus the renowned experiments of Sir J. B. Lawes and Dr. Gilbert at Rothamsted, and the experiments by the late Dr. Voelcker at Woburn, for the Royal Agricultural Society, yielded the following results, where equal quantities of nitrogen were applied as sulphate of ammonia and nitrate of soda respectively:—

	ROTHAMSTED.		WOBURN.	
	Barley.	Wheat.	Barley.	Wheat.
Sulphate of Ammonia—				
Bushels ...	43½	31½	41½	29½
Weight per bushel (lbs.) ...	45½	60½	52½	57½
Nitrate of Soda—				
Bushels ...	48	37½	42½	28½
Weight per bushel (lbs.) ...	48	59	52½	56½
Aver. of 18 yrs.			Aver. of 6 yrs.	

At Rothamsted the ammonia salts were applied in the autumn; but at Woburn in the spring. In both cases the nitrate was applied in the spring; and it is evident that there is no inherent superiority of nitrate of soda over sulphate of ammonia and chlorides, for they were mixed at Rothamsted. I have, however, brought forward these results because they illustrate very forcibly how much the value of a manure (and especially a manure like sulphate of ammonia) depends upon the time of its application. Undoubtedly the best time to apply sulphate of ammonia is in the spring—early spring—and in damp weather. And this is why the Woburn experiments yield more favourable results. Had the nitrate of soda at Rothamsted been applied in the autumn, it would have been largely washed out of the soil, and proved useless; and then the sulphate of ammonia would probably have yielded much larger crops than the nitrate. The fact that the sulphate remained in the land all through the winter, and produced a crop very nearly as good as the nitrate applied in spring, is a strong proof of its great value as a manure. In fact, the only legitimate conclusion which can be drawn from the preceding is that the nitrogen in sulphate of ammonia is every whit as valuable as the nitrogen in nitrate, provided the sulphate be properly used. But there is another advantage possessed by sulphate of ammonia, as opposed to a direct disadvantage under which nitrate of soda labours. It is this: Nitrate of soda will often prove of more harm than good on stiff clay soils; while on such soils, sulphate of ammonia proves a most valuable manure. Indeed, there is no soil upon which sulphate of ammonia has proved to have any injurious effect; while there is evidence of farmers having found nitrate of soda injurious on their wet stiff clays.

It must not be supposed for a moment that in upholding the value of sulphate of ammonia, I wish to detract from the value of nitrate of soda. Each has its proper use; and each to give good results, requires care and judgment in its use. There are circumstances and conditions when, as shown, sulphate of ammonia is superior to nitrate of soda; but there are equally circumstances and conditions, when nitrate of soda is superior to sulphate of ammonia. This, however, is not the place to enter into the conditions. All that I wish to point out to gas companies and sulphate of ammonia manufacturers is this—that sulphate of ammonia is most valuable as a manure, and can be applied in the majority of cases with as great advantage as nitrate of soda. The unit value of nitrogen therefore in these two substances is (for the farmer) identical; so that the price of sulphate can never be above that of nitrate of soda, except in so far as it contains 20 parts of nitrogen to 16 parts in nitrate of soda, and the market value of these two articles must regulate one another.

But the question of demand must be taken into account; into the supply of sulphate we need not inquire. What the manufacturers want is to create—or rather to increase—the demand. Those interested in nitrate of soda have already realised the importance of this; and hence, no doubt, the tempting bait of £500 which has been offered for the best essay on its advantages. That this essay will be in strict accordance with scientific and proved facts is certain from the names of those who have been selected as judges. Hence it will carry great weight and conviction; and the impetus which will be given, not only in England, but throughout the world, to the use of nitrate of soda as a manure, will be immense. Some twelve months at least must elapse before the prize essay can be published; and the producers of sulphate of ammonia will have none but themselves to blame if they refuse to utilise the interim in making more widely known the advantages of sulphate of ammonia as a manure—advantages which are as real, and as well proved, as any of those which can be brought forward in favour of nitrate of soda.—*North British Agriculturist.*

AN ALARMING DISEASE AFFLICTING A NUMEROUS CLASS.

The disease commences with a slight derangement of the stomach, but if neglected, it in time involves the whole frame, embracing the kidneys, liver, pancreas, and in fact the entire glandular system; and the afflicted drag out a miserable existence until death gives relief from suffering. The disease is often mistaken for other complaints; but if the reader will ask himself the following questions, he will be able to determine whether he himself is one of the afflicted:—Have I distress, pain, or difficulty in breathing after eating? Is there a dull, heavy feeling, attended by drowsiness? Have the eyes a yellow tinge? Does thick sticky mucous gather about the gums and teeth in the mornings, accompanied by a disagreeable taste? Is the tongue coated? Are there pains in the sides and back? Is there a fullness about the right side as if the liver were enlarging? Is there costiveness? Is there vertigo or dizziness when rising suddenly from a horizontal position? Are the secretions from the kidneys scanty and highly coloured, with a deposit after standing? Does food ferment soon after eating, accompanied by flatulency or a belching of gas from the stomach? Is there frequent palpitation of the heart? These various symptoms may not be present at one time, but they torment the sufferer in turn as the disease advances. If the case be one of long standing, there will be a dry, hacking cough, attended after a time by expectoration. In very advanced stages the skin assumes a dirty brownish appearance, and the hands and feet are covered by a cold sticky perspiration. As

THE INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA—SATURDAY, OCTOBER 3, 1885.

[No. 40.]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING 23RD SEPTEMBER 1885.]

Madras.—General prospects fair, much improved in Bellary and Anantapur under the recent heavy rains.

Bombay.—Good rain throughout the Deccan and Southern Mahratta Country. Condition of crops and grazing much improved by it, more rain urgently needed in most districts of Guzerat and in parts of Tanna and Colaba. Preparations for sowing commenced in parts of Nasik, Rajpore, Belgaum, and Broach. Standing crops injured by rats and worms in parts of Hyderabad. Cholera in parts of fifteen; fever in parts of twelve; and cattle-disease in parts of nine districts.

Bengal.—Rain in almost all districts, but generally not so much as in previous weeks. The comparative cessation of rain has been very beneficial to all crops. *Etendu* harvest is proceeding, and late rice crop on lands not inundated is doing excellently. Floods have done more or less damage in many places, particularly in parts of the Burdwan and Presidency Divisions. Price of rice generally continues high. Fever is beginning to be prevalent in some districts, but general health, on the whole, is fair.

N.W. Provinces and Oudh.—A slight sprinkling of rain in some places; more is needed in other places both for rice crops and *roti* sowings. General prospects are, however, good. Cholera generally abating; fever prevalent in places, as also cattle-disease, but general health continues good.

Punjab.—Slight rain. Health and *therof* prospects generally good. *Harvesting* commenced in the south-east. Prices stationary.

Central Provinces.—There has been a good fall of rain in the districts in which it was most wanted, and prospects have much improved, but more rain is required. Rice on high land in the Chuttagunh division has been damaged by lack of moisture, and is reported to have been ruined in Nambulpore.

British Burma.—(19th September).—Cholera slight in six districts, elsewhere public health good, cattle disease slight in eleven districts, elsewhere health of cattle good. Transplanting nearly completed. Rains reasonable.

Assam.—Weather fair in Gowhatty. Fever very prevalent, *in* *the* *city* still in full force, cattle disease reported from some mouzahs. Transplantation of *ash* *than* nearly finished. Prospects of all crops good. Whole country flooded more or less in Sylhet. *Ass* paddy much damaged, also *in* *the* *city*; injury to *ass* apprehended. Much mortality in south Sylhet and Naliganj from fever. Transplanting of *ash* and reaping of *ash* crops progressing in Cachar; prospects of *ash* good. *Ass* *in* *the* *city* being sown in Debrughur where the prospects of tea and other crops good.

Mysore and Coorg.—Standing crops are said to have improved but more rain at an early date is urgently required throughout the State. Outturn of *harvest* and *derugs* in Tumkoor poor. Agricultural operations reported from some places. Prospects of season slightly improved, except in northern Tumkoor, where reported indifferent, and in Chitaldroog reports bad. In Maldan taluks of Shimoga and Kadar prospects said to be *in* *the* *city*, except in the case of the Nagar taluk. The fall of *rain* in these two districts on the 12th and 13th instant nowhere exceeded two-thirds of an inch, and was, for the most part, insignificant. Drinking-water procurable, but scanty, pasturage on the whole increasing. Cattle continue in poor condition. Prices not materially altered, except in Shimoga, where they are said to be rising rapidly. Public health good; no cholera deaths reported for the week. Crops in good condition in Mercara. Picking of cardamom crop commenced. Prices of *ash* *in* *the* *city* slightly risen. Prospects of season and public health good.

Madras and Hyderabad.—The rainfall of the week has been beneficial to the crops. Wheat 22 and *in* *the* *city* 26 seers per rupee. *Ass* rain wanted in parts of the districts, and urgently in Akota and Jalgaon taluks. Crops generally doing well. Cholera has disappeared from Patdur taluk. Price—wheat 12, coarse *ash* 12, white *in* *the* *city* 12, yellow *in* *the* *city* 12, and *in* *the* *city* 12 seers per *in* *the* *city* rupee.

Central India.—Weather cloudy, but cooler; more rain required urgently throughout the *in* *the* *city* and among *in* *the* *city*. Prospects

good. Cholera continues in parts of Rewah State. Health fair other-
wise. Prices stationary.

Rajputana.—Tanks, wells, health, and crops good. Weather fair and warm. Clouds toward evenings with short heavy showers. Jodhpore city tanks all full. Wells filling up. Generally crops needing rains; rain fell more or less in north-eastern districts. Crops likely to suffer where rains are delayed. Prices tending to rise in some parts, stationary otherwise.

Nepal.—Weather getting cold. Prospects good.

Editorial Notes.

We notice that a survey of the whole district of Tanjore has been sanctioned. The *in* *the* *city* are to take precedence of that of the other portions of the district.

The latest reports from the various tea districts are not favourable on the whole, especially those from Sylhet, where very heavy rain has fallen. In Assam the weather has been wet and cold, and many of the gardens of this district are considerably behind in their outturn.

It is said that the receipts of the American crop at the ports keep comparatively small, and American shippers have evidently been taking a large proportion of the supplies, as shipments to Europe are light. Of these, moreover, the continent is taking a much larger proportion than last season, a feature which is not unlikely to have an important effect on Liverpool later on.

The Kent county authorities have received information of a serious outbreak of pleuro-pneumonia in the Sittingbourne division. The disease has affected a herd of dairy cows; one has died, and another has been ordered to be slaughtered. The place is declared an infected area under the Contagious Diseases Animals Act.

"Dinner by electricity" reads novel, but such is, nevertheless, the latest application of this subtle fluid. We are told that recently electrodes connected with a dynamo of the power of 40 ordinary Daniell cells were put into 45 gallons of fresh milk, and in exactly 4½ minutes butter was produced. The quantity obtained was fully equal to that procured in the ordinary way, and the quality perfect.

"Turn far," says the *Farmers' Review* in a recent issue, "the evidence before the British Ensilage Commission has been entirely favourable to the use of ensilage, especially for dairy cows. Dr. Voelcker candidly conceded in his evidence that little practical dependence can be placed upon chemical analyses for the feeding of animals. He believes that food may be ever so good, yet, if the animal does not like it, it will not make good meat. From the high attainments of this witness, it will be well for some of our chemists to bear his evidence in mind."

Our Acting Collector of Trichinopoly, referring to our issue of the 11th July last, at page 327 of which was published a method for the destruction of *occidentalis*, enquires the extent of the "hegah" therein referred to, in square yards. The "hegah" varies in almost every district, so that no hard-and-fast rule can be laid down by which the exact

measurements of a "beegah" can be ascertained. That, however, referred to in our issue of 11th July last, is intended to mean a *Bengal beegah*, which is equal to 1,600 square yards; 3½ Bengal beegahs being equal to one acre.

In connection with the tenth annual Dairy Show, to be held at the Agricultural Hall, Islington, early next month, there will be a conference on October 7th, at which papers will be read and discussed on several dairy questions. Sir John Lawes, Bart., will contribute one "On the necessity for some change in the Law in regard to the Adulteration of Milk;" and Professor Fream, of the College of Agriculture, will read one on the subject of "Milk Registers." The list of prizes for competition amounts to nearly 2,000l., and embraces every kind of dairy cattle, produce, utensils, vehicles, appliances, &c. The Show is under the control of the British Dairy Farmers' Association, which, under the presidency of Lord Vernon, has enrolled about 200 new members since the last Show.

We learn from one of our exchanges that the agricultural returns for Great Britain, which have just been issued from the Agricultural Department of the Privy Council Office, show that the acreage of land under wheat has decreased during the last twelve months by over 11 per cent, while the acreage under barley has increased by 4 per cent, and there is a slight increase in the acreage under oats. The number of cattle in Great Britain has increased by 5 per cent in the twelve months, and the number of sheep and lambs has increased by something over 1 per cent, but the number of pigs has fallen off by 7 per cent.

Owing to the lateness of the season, indigo manufacture is not expected to close in Bengal until about the end of last month. The results will probably be less favourable than were anticipated, as the produce from the second cuttings has been bad. The nearest approach to an estimate of the crops yet made puts it down as between 52,000 and 53,000 maunds, of which about 12,000 are *choona*. The reports from Benares and the North-West Provinces are growing worse. Very serious damage has been done to the crop by the late heavy rain, and, though the weather is now improved, it is too late to be of much use. It is expected that the yield of these districts will fall very far short of that of last year.

A *Contemporary* informs us that in connection with the attempt to ascertain the commercial value of the products of the *babul* tree, Government have directed further and more systematic experiments than hitherto to be carried out to ascertain the average outturn of bark and pods, and steps are to be taken to ascertain the areas of *babul* trees sufficiently near to one another to render it likely that it can be worked with advantage. From experiments hitherto made, it has been roughly estimated that the average outturn per tree of pods, with the seeds removed, would be about 50 lbs., and that of dry bark about 125 lbs.

We understand that the Ahmedabad Horse Show of this year was very successful. The total number of animals exhibited was 619, as compared with 603 in the preceding year, and more than a fourth of this number were the produce of Government stallions. A marked improvement was also noticed in the general condition of the brood mares and the young stock exhibited. It is incidentally mentioned that this part of the Bombay presidency has been swept clear of every decent animal between 12-2 and 14 hands for baggage ponies and other requirements for Quetta. Fortunately no mares have been bought, and as these are still in the country, the Government is urged to avail itself of this exceptionally favourable opportunity of improving the stock by purchasing six more stallions. Otherwise northern Guzerat will not on another occasion be able to supply the animals that have lately been forwarded to Bombay. The Bombay Government has given instructions for carrying out the above proposal.

A *Southern India contemporary* says:—"We are glad to note that our local Forest officers have taken a new departure, and instead of the inevitable blue-gum to which they have hitherto confined their planting operations, are now

planting a very ornamental and aesthetic-looking tree whose botanical name we are not sufficiently happy to possess. Many thousands of these plants may be seen growing luxuriantly in the vicinity of the Aramby plantation, and form a pretty contrast to the adjacent sombre-hued eucalyptus trees. The colourless beauty with which the Forest Department cling to the cultivation of blue-gums, has become proverbial, and it is a decided relief to see the monotony of blue-gum groves agreeably broken by trees of other varieties." The tree referred to is probably the *Australian Wattle*.

THE Prussian Statistical Department has just issued an important report on the harvest prospects of the kingdom of Prussia, founded upon information about every district collected through the local agricultural societies. Assuming 100 as a representative figure of an average harvest or crop, the following is the estimate for the whole kingdom:—Wheat, 93 per cent; rye, 91; barley, 93; oats, 91; beans and peas, 93; potatoes, 98; turnips, rape, &c., 92; clover, 92; meadow hay, 98. East and West Prussia and the Rhineland seem to have the best prospects; Silesia and Brandenburg are at the lower end of the scale. The best wheat harvest is in the province of East Prussia; rye in the Rhineland; barley in West Prussia, Saxony, and Rhineland; oats in West Prussia; beans, &c., in Schleswig-Holstein; turnips, &c., in the Rhineland; and clover and hay in Hanover.

THE Shevaroy Planters' Association addressed a memorial to the Government of Madras, praying that Government assessment on all estates on the Shevaroy Hills be remitted for one year, as owing to a succession of bad seasons, the ravages of leaf disease, and the continued depression of the coffee market, the planting enterprise on these hills has come to be in a critical condition. The Association made out a very strong case for Government concession, but with very little success, as the Collector of Salem did not support the application, beyond recommending six months' grace for the collection of the Government *kist* from those planters who have been very seriously affected by the failure of Messrs. Stanes and Co. The Government of Madras, while sanctioning such postponement, have decided that, in the case of the proprietors "hopelessly involved," there can be no object in postponing the demand. They are not prepared to go further than this, nor to direct a general suspension of collections irrespective of individual circumstances.

Iron tells us that at a lecture on coal recently delivered at Philadelphia, it was stated by the author that the United States have an area of 140,000 square miles of coal-fields; 100,000,000 tons of coal were mined in the country last year, enough to run a ring around the earth at the equator 5½ feet wide and 5½ feet thick, and there is enough coal in the United States to supply the whole world for a period of 1,500 to 2,000 years. The question of the exhaustion of the coal supply, therefore, is not immediately important. The anthracite coal in Pennsylvania, it is stated, will last 250 years, while the bituminous coal in the same district will supply the world for fifty-seven years, and the United States for 350 years. The same lecturer stated that it took a prodigious amount of vegetable matter to form a layer of coal; that it was estimated that the present growth of the world would make a layer only one-eighth of an inch thick, and that it would take a million of years to form a coal bed 100 feet thick.

Messrs. CHARRIERS and Co., of Lyons, writing on August 7th, 1885, take the following view of the Lyons silk trade:—

As is usual at this time of year—a period between seasons—business drags along somewhat slowly, and we have to report a dull market for most classes of silk during the past months. The improvement produced on Europeans by the deficit in the Indian crop has been maintained, but without further development. The market for these sorts is now extremely quiet, and some sellers already show a certain impatience to sell. With regard to China, the very reduced scale of shipments from Shanghai has enabled holders to obtain a slight further advance. Most Chinese exporters seem determined not to buy beyond their daily wants, owing to the still very limited consumption at China ports, so that they have to look for guidance in their operations. In Canton markets

and Japan, business has been very dull. Canton silures, on the contrary, have enjoyed a regular inquiry at former prices. On the piece-goods market, the demand is still for mixed articles and cheap class goods. This explains why the activity on the looms is not productive of a brisker inquiry for silk; and it seems as though a return of fashion to pure silks could alone bring a permanent revival on the raw material.

The following statistics of the imports of dairy produce into England, we take from the *North British Agriculturist* :—

According to the B Bill of entry, we imported 198,212 cwt. of butter and butterine in July, against 185,007 cwt. in the same month of last year. As much as 79,277 cwt. was received from Holland, against 82,119 cwt., while France contributed 38,779 cwt. against 43,670 cwt., Sweden 10,389 cwt. against 9,667 cwt., Germany 16,615 cwt. against 8,102 cwt., and the United States (Atlantic) 14,711 cwt. against 5,802 cwt. Of the above total London received 28,300 cwt. against 22,680 cwt., Grimsby 12,065 cwt. against 10,941 cwt., Harwich 14,913 cwt. against 16,275 cwt., Hull 23,073 cwt. against 20,071 cwt., Newcastle 29,889 cwt. against 24,125 cwt., Southampton 27,293 cwt. against 27,671 cwt., and Leith 21,820 cwt. against 17,528 cwt. Our imports of cheese for the month came to 340,364 cwt. against 358,345 cwt. Holland sent 37,983 cwt. against 30,663 cwt., Canada 186,230 cwt. against 128,818 cwt. and the United States 163,828 cwt. against 105,652 cwt. The quantity landed at London was 15,555 cwt. against 14,855 cwt., Liverpool 187,020 cwt. against 249,379 cwt., Bristol 38,022 cwt. against 23,818 cwt., and Glasgow 61,776 cwt. against 48,741 cwt. During the same month the eggs we imported amounted to 646,464 great hundreds against 642,849 great hundreds. All the subjoined figures represent great hundreds, our chief sources of supply being France 323,775 against 299,833, Germany 144,361 against 158,189, Belgium 130,994 against 135,350, and Denmark 30,179 against 44,199; while Newhaven received 136,469 against 103,788, Harwich 131,084 against 125,450, Southampton 119,840 against 110,331, London 55,938 against 47,500, Grimsby 37,724 against 30,224, Hartlepool 85,718 against 100,344, Newcastle 43,265 against 45,451, Weymouth 293 against 33,906, and Leith 5,424 against 10,644.

DR. TRIMEN, Director of the Royal Botanical Gardens, Peradeniya, in reply to the request of the Madras Government for detailed information regarding his method of drying and preparing leaves of the *Erythroxylon Coca*, has sent the following reply :—

I have prepared a single small sample only of coca leaves from trees in this garden. This was in February last during the hot dry weather. No special precautions were taken. Fully grown leaves were carefully picked and at once dried gradually in the air under the shade of a verandah, the process being finished off in the sun. The complete drying took ten or eleven days, and the leaves lost half their weight in the process. When finished the leaves were flat, greyish-green and mostly unbroken, forming a good-looking sample. I am not aware whether the plan followed is the best that might be employed; possibly more rapid drying would be found preferable. A sample packed in a tin-box was sent home, and on analysis by Mr. D. Howard was found to contain 0.22 per cent of pure cocaine, a fair but not large proportion. I published this result in the Ceylon newspapers on 10th April last.

I understand that some analyses of the young leaves have been recently made by Mr. Hooper, the Government Chemist at Ootacamund, and I should feel obliged if you would request the Madras Government to furnish you with the result of these assays for my information here.

We have not seen Mr. Hooper's report of his analysis, but should like to.

A few months ago we had occasion to notice the formation of an Agri-Horticultural Society at Narsapore in the Southern Presidency. The Society had asked for two acres of rent-free land, or at a nominal assessment. Sanction to this had been deferred pending the opinion of the Agricultural Reporter to Government. This has now been received; and Mr. Benson, while he thinks the proposals referred to him are "hazy and indefinite," yet considers that Native gentlemen, who show a disposition to form societies for the promotion of agricultural enterprise and improvements, should meet with every encouragement from Government; as, if we can enlist a genuine

interest of this sort in the work of our department, it will be lightened, and its effect vastly increased.

He adds at the same time, that though it is impossible that anything real can be done in the way of farming on so small an area as two acres, still that the formation of an agri-horticultural garden of that size at Narsapore is likely to be beneficial, and worthy of assistance to a degree even more than asked for in the papers referred for his opinion. He considers that the Agricultural Department would be better able to judge whether Government assistance should be continued to the society than any other authority, and control in this respect might be left to it, as has been done in the case of the Madura farm. Sanction has been conveyed to the proposal of the Director of Revenue and Agriculture that the land asked for should be assigned rent-free, on the following conditions :—"that the garden be subject to inspection from time to time by the Collector and Agricultural Reporter to Government; and that, in the event of the experiment being found to be a failure, or the object for which the grant was made being departed from, the land should be liable to immediate resumption without allowance for any improvements." It is not intended to allow any fixed term of years for the purpose of making the garden. The society having got the concession will, we hope, prove that the grant was not made in vain.

It is satisfactory to note that the system introduced by the Madras Government five years ago of establishing Government fish-curing yards, with a view to secure a supply of properly cured fish for the market, has worked with beneficial results, not only to the consumers but to the Government itself. From the report for the half-year ending 31st March 1885, it appears that the operations during this period had made very material progress. Compared with the corresponding period of the previous year, the number of yards worked shows an increase of 14, i.e., 123 against 109; and, in spite of the damage by flood in some of the southern divisions, there was an increase in the quantity of fish brought to be cured of 62 per cent, viz., 14,844 tons against 9,141 tons. Taking the figures for the whole year, the quantity of fish brought to be cured rose from 11,789 tons in 1883-84, to 20,108 tons in 1884-85. As a matter of course, there was much opposition to the measure at first, but it was determined to replace the unwholesome stuff sold previously, as dried fish, by a better supply, and a system of issuing licenses was established. The fish-curers objected to pay for these licenses, but finding that there was no relaxation of the system, they have come round generally to accept the inevitable. In South Canara the fishermen have not yet become reconciled to the system, and have been slow to avail themselves of the opportunities which have proved so attractive in Malabar, probably in the expectation that the restrictions on the use of salt-earth might eventually be removed; but now that they have been assured that relaxation of the law in their favour is not to be looked for, they may be expected soon to resort to the yards for the purpose of curing their fish. Financially, the operations of the half-year under review have resulted in a gain to Government of Rs. 6,081, which reduces the accumulated deficit of previous years by one-fifth. The experiments made by the department in improved methods of curing have, so far as they have gone, proved successful, and are to be continued.

The *European Mail*, referring to the subject of agricultural education at home and abroad, says :—

Although the French Government voted 3,512,000fr. for agricultural education this year, the *Méti Agricole* says it is not enough, and that the several departments need to complete the organization. In England we are accustomed to think that agricultural instruction is very liberally provided for in France; but our French contemporary complains that they have in France only one institute of agriculture, one national school of agriculture, and one of horticulture, 14 schools of practical agriculture, two shepherd schools, one school of practical horticulture, two forestry schools, 23 farm schools, one cowhouse for breeding, two silkworm rearing schools, two primary agricultural schools, one agricultural and two horticultural courses of lectures in primary schools, 43 orphanages and

agricultural colonies, 86 departmental professors of agriculture, three chairs of agriculture in Algeria, four chairs of agricultural chemistry and 31 agricultural stations; while Germany has 14 agricultural institutes, 451 primary agricultural schools, 71 schools of agriculture, seven veterinary schools, nine superior institutes of pomology and arboriculture, 84 agricultural schools of various kinds, 15 schools of practical horticulture, 11 dairy schools, five schools of agriculture for girls, one school of sugar refining, one school of distilling, 36 special courses of agricultural lectures, 65 agricultural stations, and 37 professors of agriculture. Italy, most persons will be surprised to learn, has three superior and 22 practical schools of agriculture, all created since 1880, six special schools, four of which are for viticulture and wine-making, and 18 agricultural orphanages and colonies dependent entirely upon the municipalities. Even little Denmark has an agricultural institute with 223 pupils, and 22 professors, 10 practical schools of agriculture, and 60 superior primary schools which give agricultural instruction.

How does India (an almost wholly agricultural country) compare with these statistics in respect to agricultural and horticultural education?

THE South of India papers are, we see, much exercised by the alleged discovery of payable lignite in French India at Bahour, within the limits of the settlement of Pondicherry, and they censure the inaction of the Madras Government for not tracing the same deposits into British territory, and adopting means for developing our own resources in this respect. The French proposal is still within the domain of speculation, and is not likely we suspect to get beyond that stage. The favorable views of the Madras press on the French scheme, appear to have been induced by the usual promising "prospectus" which has so often proved a delusion and a snare. Picked specimens and manufactured samples are not reliable data for practical conclusions as to remunerative returns. Figurative and ornate diction pleases the fancy, but does nothing towards refilling the pocket which it so often empties. The history of Indian gold-mining is perhaps, the most wonderful record of human infatuation of the century. It seems scarcely credible that in face of the millions sacrificed in this speculation, new fields for investment should be wanted to meet the public craving for excitement: and that such ventures should obtain public support, within so short a time of such expensive lessons as the Wynad failures, is still more surprising. The latest project is this "Bahour lignite" undertaking, which is brought forward in the teeth of the opinion of the Geological Survey, that the deposits are little more than carbonaceous mud. Even should this mineral fuel prove as rich in carbon as is stated, the possibility of working the deposits in soil teeming with water under artesian conditions, would we understand be very unlikely.

A LONDON letter to the *Statesman* says:—The latter half of this century has been accentuated by exhibitions of which London has had nine—a classic number. Those held in the provinces have had, in their different directions, quite as important results. They have been special. Besides the vast improvements in livestock breeding, which those devoted to cattle have initiated, it would be difficult to fix the value of the impetus given to high-class farming by exhibits of agricultural implements and machinery. Shows of this nature have a double action—they not only cheapen and facilitate labour, they quicken the inventive faculty. Perhaps the largest display of this sort has this month been held in Essex, on the extensive grounds of the Shorthorn Dairy Co., Limited. A goodly number of London pressmen were present, and kindly entertained by Mr. Collinson of Hull, the Managing Director of the Company. The high class farmer, at such shows, appears in a special rig out. He does not regard life through a rose-coloured lens; he is naturally a pessimist. If drought weighs the golden grain, it shrivels the root crops; so, come sun, come shower, weather never fits into his needs. Perhaps no one understands his moods better than his inseparable companion, his little dawg. The London *Morning Post* and the *Daily Chronicle* gave elaborate articles on the different machines, and on the magnificent cattle with which the Company's farm of 2,200 acres is stocked. An enthusiastic farmer, fortunately independent of bad seasons and foreign competition, whom I met while flying north, decanted to me on the wonders of Bernard and Lake's new patent thatcher, which he had bought; on W. A.

Wood's patent string binder, which his friend Col. Griffin had induced him to buy; and one of the steam ploughs he would certainly go in for before November, his whole lying between a steam plough and one of Messrs. Ransome's wide-tine ploughs.

Almost all the machines were shown in active operation, and my *compagnon de voyage* described with plying hammer the action of a primeval flail wielded by a venerable labourer, side by side with the puffing and dextrous thrashing machine exhibited by Messrs. Ransome. This flail had been in Mr. Collinson Hall's family for eight centuries. "I hadn't," he said, "the remotest intention of buying even a spade when I entered the place: but I believe, though I've parted with a stiff sum, I was a richer man when I came out—so vive les exhibitions!"

.

A few weeks back we noticed the unsatisfactory results of fibre experiments generally in Madras. We are, however, glad to find that samples of fibre prepared recently in the Government Farm at Saidapet from Manila hemp plantain (*musa textilis*) and the common plantain tree (*musa paradisiaca*) and which were sent for valuation to Messrs. Collyer and Co., have been pronounced of better quality. Messrs. Collyer and Co. describe the fibre of *musa textilis* as of "good length, good colour, fairly clean, but mostly deficient in strength; fibre fine, but very brittle; value probably about £30 per ton." They add that this sample is superior to most of the samples sent from Southern India; but that it is much inferior to the Manila hemp grown in the Philippine Islands. With regard to the fibre of the *musa paradisiaca*, it is said: "This sample is also superior to many we have seen, being good length, fair dullish colour, fairly clean, varying strength, mostly brittle and weak; if fully equal to sample, would probably realise about £25 per ton." It seems to us that the defect in the fibres produced in Madras is due rather to the mode of preparation than to the natural qualities of the fibres. It is unfair, therefore, to pass a verdict on the merits of the fibres, on badly prepared samples. Mr. Price drew attention to this very point very recently, and we quite agreed with him in thinking that unless we can send properly prepared samples for valuation in the London markets our experiments with various fibres in this country are mere waste of time, trouble, labour, material, and money. The following remark by Messrs. Collyer and Co. on the present samples is worth noting:—

The great abundance of superior fibres in this market renders the sale of any similar to above very difficult except at very low prices; they will probably be more valuable for local use, and we have also reason to believe that if spun upon the spot whilst the fibre is fresh before it gets thoroughly dried, a rope can be made much more durable and much stronger than the same fibre would produce if spun here.

.

MR. PAT DOYLE, C. E., F. G. S., has addressed the following letter to a Madras contemporary regarding the coal supply of Southern India:—

"Allow me to remark, with reference to the concluding part of the leader in your issue of the 17th instant, re 'The Coal Supply of South India,' that there is a great difference with a wide distinction between my *bona fide* commercial transaction and Mr. Deloncle's veritable speculation. It is hardly fair to claim to attempt to introduce Bengal coal into Madras with a project—the Bahour scheme—as yet within the domain of imagination, and opposed to science and experience, or even to common sense. Bengal coal is extensively used for steam purposes—a proved and acknowledged success. The out-put is about 1,500,000 tons per annum, of which nearly 1,000,000 tons is consumed by locomotives on upwards of 4,000 miles of Railway in Bengal, the N. W. P. and Oudh, the Central Provinces and Rajputana. In the latter locale it is found economical to transport this coal 1,000 miles by rail, and use it at a cost falling little short of Rs. 40 per ton, as railway fuel. Madras is 800 and 8,000 miles distant respectively from the centres of coal production in Bengal and Great Britain. Madras, however, is entirely supplied by the latter. In the face of these facts and figures you will, I am certain, concede that the aspirations of finding a market in Madras for Bengal coal have not been raised on a basis of fact, or deduced from data of a very imperfect kind. Any ventures made in this direction would be purely commercial—*bona fide* business—in which the parties concerned would be relying on their own resources and not trading upon public credulity. How to obtain better samples of fibre for valuation in the London markets is a matter of great importance."

that as the Bazar lignite deposits is effectually disposed of by the fact that even should they prove worth working, the possibility of their being so remuneratively in soft ground teeming with artesian water is remote and improbable. It must not be forgotten that whatever the outcome may be in the Singareen field, the production there will, for many years after the opening of workings, go to meet the requirements of the Nizam's Railways. The Bombay-Mysore State line would be the first to absorb any surplusage from this source. From information received by last mail, I am in a position to state that a company is now negotiating with the Nizam's Government for the concession of the mining rights in the Hyderabad dominions, which, I presume, will include the Singareen coalfield. My own personal knowledge of the Southern extension of this area in the Godavary District is in favor of further prospecting by Government, with the view of testing satisfactorily, and disposing definitely of the question of payable coal in British territory in the Madras Presidency."

We take the following from the *Globe*:-

From a Parliamentary return just issued, on the moral and material progress and condition of India during the year 1882-83, it appears that the tea plant grows wild in Assam, in both the Brahmaputra and the Surma valleys, or rather in the hills dividing these two valleys; but its cultivation on the Chinese method was first experimentally attempted by the Indian Government in 1834. Chinese seed was at the same time introduced, and it has been found that the most profitable plant is a hybrid between the indigenous and the Chinese varieties. Assam is still the great home of the industry; but tea planting is also securely established at Darjeeling in Bengal, along the foot of the Himalayas as far west as Simla, at Chittagong on the further side of the Bay of Bengal, and on the Nilgiris and other hill ranges in the south. It has been started with fair prospects in Chota Nagpore and in British Burmah. Except in Kangra district in the North-West Provinces, tea-planting is entirely in the hands of Europeans. The coffee plant first attracted the attention of European planters in about 1840, but the industry did not make much progress until 20 years later. Since 1860 it has spread with great rapidity throughout the entire region of the Western Ghats south of Kanara, including the greater part of Coorg, Hassan, and Kolar districts in Mysore, the Nilgiris, the neighbouring portion of Malabar districts, and (more recently) the native States of Travancore and Cochin. It has also extended to the Shevaroy Hills in Salem district and to the Palni Hills in Madurai district; but repeated efforts to acclimatise the coffee plant in other parts of India have not met with much success. Coffee remains a product of the extreme south even more exclusively than tea remains a product of Assam. It differs from tea in being largely grown by native cultivators as well as by European planters. Unfortunately, coffee is a very delicate plant, being exposed not only to the vicissitudes of the season, but also to several insect pests of its own. Of late years the crop has not proved remunerative either in Southern India or in the adjoining island of Ceylon; in 1871-72 the total export of coffee from India reached their maximum, 307,296 cwts.; in 1877-78 they fell to 238,567 cwts., and by 1882-83 they had only recovered to 361,008 cwts. The corresponding values do not show such large variations, for East Indian plantation coffee is always in demand in the English market. Cotton is cultivated in every part of India for local consumption; but the great cotton-growing tracts, which furnish the bulk of the export, are Gujarat, Khandesh, and the Southern Mahratta country (all in Bombay) and, the neighbouring province of Berar. The cultivation was immensely stimulated at the time of the American war, when the ordinary sources of supply to the English market were closed. The exports rapidly rose till they attained the maximum of 7,000,000 cwts., valued at £35,000,000 in 1865-67. After that date they dropped as rapidly as they had risen, the minimum of 3,000,000 cwts., valued at less than £8,000,000, being reached in 1878-79. There has since been a marked increase year by year, and by 1882-83 the quantity had risen to 5,250,000 cwts., valued at £18,000,000.

In our issue of June 8, 1885, page 269, we noticed the unsatisfactory results of the experiment with silk-worms in Madras, the cause of which was attributed to the "inability of obtaining a sufficient supply of mulberry leaves, either on the hills (Salem) or from elsewhere," and that the worms "refused to feed on anything but mulberry leaves." The result was that a large number of worms, chiefly the big ones, which were ready to spin, had died. Although the mulberry tree is common enough throughout the length and breadth of

India, yet there was an instance when it was found quite impossible to obtain mulberry leaves. This difficulty may occur at any time, but those engaged in sericulture will be glad to know that a method has been found, whereby they may guard against the recurrence of such a state of affairs. The method we refer to is nothing more than that of *ensiling mulberry leaves*. In the last number of the *Gardener's Chronicle* to hand (September 5, 1885), we find the following quotation on this subject from the *Journal of the Society of Arts*:-

"During the silk-worm rearing season in Northern Italy, a large quantity of mulberry leaves are sent by rail from one place to another, and in many cases the railway administration runs special night trains for this purpose. The leaves are packed loosely in sacks, and often arrive at their destination far from fresh, and consequently, if not totally unfit, at all events cannot afford a wholesome food for the nourishment of these insects. An experiment was made during the present season, by a silk-producer in Lombardy, in sending the leaves compressed; and for this, a bale was made, weighing 110 kilos, by placing the leaves between two round pieces of board (in this case the bottom of barrels), and compressing them in an ordinary wine-press; the bale was then firmly secured with iron wire. By some oversight, this bale of compressed leaves, made on May 23, was not forwarded to Milan, and from thence to Niguarda, until the morning of the 31st, and consequently it did not arrive at its destination until later. On opening, the bale of leaves, with the exception of about two inches in thickness round the outside, were found to be perfectly fresh and sweet, and even these were only faded and found to be not unfit for food."

"This is a conclusive proof that the nutritive qualities of the leaves can be preserved for some time, if compressed, and the air thus excluded from them; care, however, must be taken not to crush them, and injure their tissues by excessive pressure. From this it would appear that a system of ensilage might be adopted with advantage for preserving mulberry leaves in the same way that it is for forage. Another advantage of such a plan would be that the leaves so compressed would be reduced in bulk, and consequently fewer trucks would be required to carry a given quantity of leaves than there is in the ordinary way; and by ensiling the leaves grown on the warm side of the Apennines—as, for instance, on the "Riviera" of Genoa, &c., it would be possible to supply the silk-worm rears of Piedmont and Lombardy during back seasons, or when, from other causes, the leaves are scarce and expensive."

With this example before them, silk-worm rears in India need have no fear of running short of mulberry leaves. In any part of the country, where there may be a scarcity of leaves, it may be supplied from other parts where the tree is plentiful. Speaking from our own knowledge of the distribution of the mulberry tree in India, we should think the N.W. Provinces, Oudh, and the Punjab would be able to meet all wants; for in these parts it abounds in more profuse luxuriance than in most others.

The following is a summary of the health, crops, and weather reports for the week ending 25th September 1885:- Rain is reported from all the districts of the Madras Presidency. In Bellary and Anantapore prospects have much improved. Elsewhere they are said to be fair, though more rain is required in most districts. In Mysore slight rain fell during the week in the Tumkooor, Kolar, and Bangalore districts, but more is urgently required throughout the State, especially in the two districts first-named and in Chitaldroog. Agricultural operations have been resumed in some places, and the prospects of the season have slightly improved, except in parts of Tumkooor, Chitaldroog, Shimoga, and Kadir. The cattle continue in poor condition, but pasturage is reported to be more plentiful.

Good rain has fallen throughout the Deccan and Southern Mahratta country, and the condition of crops has been much improved. In most districts of Gujarat and in parts of Tanua and Colaba more rain is urgently needed. The *harif* harvest generally promises well, but preparations for the *rahi* crops have commenced in places. In the Baris and in Hyderabad the rainfall of the week has been beneficial to the crops, which are generally doing well. In parts of Andhra more rain is badly wanted. In Rajpootana more rain is wanted in several States, but crop prospects are, on the whole, favourable. Rain is also wanted throughout the Central India States.

From the Central Provinces good rain is reported in the districts in which it was most wanted, and prospects have much improved. More rain is, however, very generally required. In the Punjab slight rain fell during the week. *Kharif* prospects are generally good, and agricultural operations for the spring crops have commenced in places. In the North-Western Provinces and Oudh the rainfall has been slight, and more rain is wanted, both for rice crops and *rabi* sowings. General prospects are however good.

In Bengal rain has been general, though fortunately less heavy than in previous weeks, and the cessation has been very beneficial. The *Madai* harvest is in progress, and late rice crops on lands not inundated are doing excellently. Floods have caused more or less damage in many places, particularly in parts of the Burdwan and Presidency divisions. In Assam much rain has fallen during the past fortnight. In Sylhet crops have been much injured by floods, which are, however, reported to be subsiding. In the other districts, agricultural prospects continue generally good.

In British Burmah the weather continues seasonable.

The public health is generally fair in most provinces.

Prices are fluctuating in the North-Western Provinces and Oudh, and in the Central Provinces. In the Shimoga district of Mysore they are reported to be rapidly rising, and a slight rise has also occurred in Coorg. In Bengal the price of rice continues high. Elsewhere prices are fairly steady.

GENERAL WILKINSON ON ENSILAGE.

We have read with interest the report submitted by Brigadier-General H. C. Wilkinson, on the Ensilage experiments carried out by him during 1884. The report is dated 28th May 1885, although it was only a few days ago that we were favoured with a copy by the courtesy of the Director of Agriculture, Bengal—a period of four months having elapsed since the date of writing.

The General has dealt with the subject exhaustively in his report, which is the most complete and satisfactory one we have seen in India since the time this method of storing green fodder first attracted attention in this country. The four opening paragraphs are devoted to an explanation of the 'leading features of the system.' We agree in the conclusions drawn by the writer, except in regard to the statement that "any enclosed space can be used as a silo"—to wit, "a hole or trench in dry ground." It is obvious that a hole or trench dug 10 feet deep in Bengal is sure to be wet and moist, which circumstance in itself is opposed to the most essential condition of a silo, i.e., that it must be water-tight. Again, we do not quite agree in the remark that "sweet ensilage will not keep." The fifth paragraph is the most important, in our opinion, as at once stamping the method with the 'hall-mark.' It runs as follows:—

"Ensilage has been found by experiment to be more fattening and nourishing than green grass; and cows fed upon ensilage give more milk, and their milk yields more cream than when they are fed upon grass."

We have italicized this paragraph in reference to its importance. Mr. D. B. Allen must have had this report before him, when he wrote us the letter, dated 10th August 1885, and which appeared in our issue of the 22nd idem; for he quoted from General Wilkinson's report, which at that time we had not seen. He said—"Indeed the General himself seems to disbelieve in the accuracy of this experiment," and he quoted the following passage in support of this statement:—"With this universal (but variable) daily decrease of yield, it has been found impossible to tabulate the advantage gained by the use of silage for increasing the yield of milk." But Mr. Allen omitted to finish the sentence, which continues thus—with a comma after 'milk,' "but during the progress of these experiments, it has been evident that the use of silage *did* distinctly retard the gradual decrease in yield, and in many instances increased it for a time." [The italics are ours.] This ending alters the meaning of the sentence somewhat, we think. However, to proceed with the General's report, we notice that he mentions three ways of loading a silo, viz., the quick, the slow, and the 'sweet

silage' system. He is decidedly in favour of the first named method. But the disadvantages are stated to be that—

"However firmly pressed down and trodden the green forage is, it still, at first, occupies from $\frac{1}{2}$ to $\frac{3}{4}$ more space than it does a week later, when fermentation has died out, so that from $\frac{1}{2}$ to $\frac{3}{4}$ of the silo space available eventually remains unoccupied."

This is, of course, a very material point; and we should think that, as this loss of space can be avoided without detriment to the silage, we incline to the slow as the better method of the two. There are, however, two opinions about the merits of the slow process. The General says:—

By this system, as the grass is not covered over till the silo is filled, but is only tramped down as firmly as possible daily, fermentation sets in at once, and progresses slowly until the work is completed.

The advantages claimed for this system are that it is much more convenient, especially for small farmers; that the action of fermentation causes the grass to settle and pack much more closely than it otherwise would, thus enabling the silo to be filled slowly to the very top, after which little settlement takes place.

That the grass, though much more fermented, is still in a state that many believe to be the very best for feeding and fattening purposes.

On the other hand, some think that during this process of fermentation the forage loses an appreciable amount of its actual bulk and weight.

With regard to sweet silage, the General makes the following remarks:—

A little partly made sweet hay is put in the bottom of the silo (to act as yeast does in bread making); green forage is then lightly loaded in on the top of the partly made hay to the depth of about a yard; this is not pressed down or trampled, so that strong fermentation sets in at once. As soon as a temperature of 122° Fahrenheit is reached, the forage is firmly trampled down, the "bacteria" of sour fermentation having been destroyed by this heat. More green forage is now added to the depth of another yard, and the process is continued as before till the silo is quite full, when it is covered over like any other silo.

If a very portion of the contents has been duly heated to a temperature of 122°, the result will be silage as sweet as good old hay.

The advantages of this system are that the very strong and disagreeable smell of sour silage is avoided, and that the silo (as in the slow loading system) can be filled to the very top.

The disadvantages are that it takes much more time and trouble; that the green grass must not be very wet with rain; and that when the silo is once opened, the contents must be rapidly consumed, as "sweet silage will not keep."

We do not, however, remember to have read or heard that "sweet silage will not keep"; but not having seen any sweet silage made in this country, we are necessarily unable to verify the statement. But it may be taken for granted that General Wilkinson had practical experience in the matter, and his assertion may be accepted as correct.

The silos used by him were all built of *pucca* masonry, so that the essential condition of air and water-tightness was fully met. He lays it down as a fundamental rule that "perpendicular sides are essentially necessary to a good silo." This point is insisted upon by all who have experimented with ensilage.

Another material point, the General might have added, is the smooth surface of the said walls. The temperature of the slow-filled silo never exceeded 89° Fahrenheit. The quantity of grass put into it was 15,300 lbs., or 191 mannds. The pressure of earth at the top was equal to 200 lbs. to the square foot. Two other silos were also filled, and were nearly similar to the first one. The fourth silo was filled on the slow-loading system, and six days were occupied in the operation. The temperature did not exceed 110° Fahr. in the heart of the silo. The quantity of grass was nearly the same. In refilling the silo in which sweet silage was made, it will be as well to quote the General in *extenso*. Filling in was commenced on 2nd January 1885:—

January 3rd.—The temperature had risen to about 115° Fahrenheit, but in no place could it be found higher than 115°.

So about two feet more green grass was shaken in on the top to try to increase the heat, as it will be remembered a heat of not less than 122° Fahrenheit is necessary in this operation to kill the bacteria of sour fermentation.

January 4th.—In the morning the heat at the very bottom of the tube, or just above the one foot layer of hay, was found, to be fully 120°, and by evening it was up to 130°. Being Sunday nothing could be done. The upper part was not above 110°.

January 5th.—Duty kept me absent till 5 P.M., but on the morning of this day fresh green grass (freed from excess of moisture as before) was lightly shaken into this silo to the depth of three feet more. At 5 P. M. the temperature was as follows:—

At 1 foot from the bottom	...	147° Fabr.
" 2 feet "	...	147° "
" 3 " "	...	123° "

Immediate steps were therefore taken to stop further fermentation, by trampling the grass as well as could be done by two men; no permanent weight was placed on it.

January 6th.—At 7 P.M. the temperature of the silo was as follows:—

At 1 foot from the bottom	...	142° Fabr.
" 2 feet "	...	123° "

January 7th.—Four maunds were added; temperature 133°.

January 8th.—Eight more maunds were added; temperature—

At 1 foot from the bottom	...	133° Fabr.
" 2 feet "	...	129° "
" 4 " "	...	116° "

January 9th.—

At 1 foot from the bottom	...	125° "
" 2 feet "	...	123° "
" 3 " "	...	121° "
" 4 " "	...	130° "

January 11th.—More grass added.

16th.—Temperature—

At 1 foot from the bottom	...	92° "
" 2 feet "	...	105° "
" 3 " "	...	127° "

The silo was covered up on this day, having taken a fortnight to load.

January 15th.—Temperature—

At 1 foot from bottom	...	92° Fabr.
" 2 feet "	...	105° "
" 3 " "	...	101° "

January 27th.—Temperature—

At 1 foot from bottom	...	92° "
" 2 feet "	...	93° "
" 3 " "	...	95° "

It will thus be seen that the highest temperature (147° Fahrenheit) had been reached on the third day after filling, and then there was a gradual falling, until the bottom temperature had come down to 92° Fahrenheit. This is in accordance with Mr. Fry's practice. The result of this operation was sweet silage.

In addition to the foregoing, General Wilkinson also experimented with pit and stack silos—the former with the object of demonstrating a simple method that could be "strictly imitated by any able-bodied peasant and his son." It merely consisted of a hole in the ground 5½' x 5½', with perfectly perpendicular sides, plastered with moist clay. Forty-two maunds of grass were filled in, and common country mats of the value of two annas were placed on the top; and the earth that had been dug out was piled on the top of the mats, until the grass had subsided sufficiently. The cost of this simple silo was only the labour of two men for two days, and two annas for mats, in addition to the cost of cutting and collecting 42 maunds of grass. What the quality of the silage thus made was, is not stated. This is to be regretted.

The stack silo was little more than four feet high when finished. It was built on a 9-inch plinth of earth, well rammed, to raise it above the damp soil. It was 5 feet in diameter at the base. The top was covered with mats, with a thin layer of clay, and heavy iron bars were used to weight it, which gave a pressure of 200 lbs. to the square foot. On opening, it was found that the air had penetrated to a distance of a foot all round the stack, which, being only 5 feet in diameter, represents a large proportion of the whole; but the centre was found to be in really good condition, and was used to feed the animals belonging to the Transport Department. Of course, it is natural to infer that the larger the stack and greater the weight, the less will be the proportionate loss by rot and mould. To explain the plan more fully, the General has quoted the

process invented by Mr. C. Johnson, of Oakwood, near Darlington, which we shall notice hereafter.

The grasses used in these experiments were *Imperata arundinacea*, or "Ooloo" of Bengal, and *Andropogon pertusus*, known in Banda as "nalwal," "palsah," and "lukur," and "palwan" and "minigar" in the Punjab. It is described as an excellent grass, not known in Bengal until discovered growing in the ditch of Fort William.

The results of these experiments, the feeding experiments, and our own comments, we reserve for next week.

WHITE SILK-COTTON TREE.

THE *Mysore Gazette* of September 12, 1885, contains some very interesting correspondence regarding this economic tree, its numerous varieties, distribution, and other information, which should be read with interest. The correspondence, it would appear, originated in a letter from Mr. Cameron, Superintendent of the Lal Bagh at Bangalore, in which he drew attention to the qualities of the silk-cotton yielded by this tree, and recommending its more extended cultivation, and conservation where it already existed. The Mysore Government, acting on this letter, circulated copies to the several Deputy Commissioners, Sub-Divisional and Forest officers, with a request that, after careful enquiry, a report may be forwarded showing in what taluks the trees are now to be found, and where their growth is most luxurious. Also, what encouragement would be necessary to extend its cultivation. Replies were received to this circular, which go to show that the tree is more or less indigenous in Southern India—at any rate, certain species of it are.

Before going further, it may be well to state that there is some doubt as to whether the tree named by the Mysore Government is the one to which particular attention is drawn, and which is believed to be indigenous to Southern India. The *Eriodendron anfractuosum* is the variety referred to. This tree belongs to the natural order of plants which come under the general head of *Sterculiaceae*, to which belong also other tribes of the same genus, such as *Gonolobus*, *Helicteres* and *Starc uticeae*, all possessing to a more or less degree a silky covering around their seeds. One of this tribe, viz., the *Helicteres*, is grown for the fibre which it yields. The Silk-Cotton tree of Northern India has long been known to be the *Bombax heptaphyllum*, (or *pendandrum*, in reference to the division of the leaf, which sometimes has five, at others seven segments), and is known to the natives of Upper India by the name of *Samul*. It is not cultivated, but is found growing in a wild state. The fluffy silk-like cotton is gathered as soon as the pods assume a ripe appearance; for if not gathered then, the pods fly open later on, and the cotton, with the seeds attached to it, is blown to the winds. The silk of this tree, however, is pronounced to be of an inferior kind, inasmuch as it cannot be twisted into thread. There are other species that yield silk-cotton, viz., *Chorisia speciosa*, *Eriodendron Samanum*, *Bombax Ceiba*, and *Ochroma lagopus*. These are all large-growing trees. To these must be added the *Calotropis gigantea*, or common *madr* of the jungles—a wayside weed, to be found everywhere in India.

The *Eriodendron anfractuosum*, which forms the subject of the correspondence, grows all over Southern India, but the natives attach no value to the silk-cotton it yields. It is by no means plentiful in any one locality; but being indigenous, is cultivated by the ryots in betel-nut gardens, owing to its fast growth, to serve as a support for the betel-nut vine, which entwines itself around the tree in its growth. According to the Assistant Conservator of Forests, Shimoga, it is very easily propagated by means of "stakes" planted 4 to 6 feet apart as these are said to "take" sooner than seed. The tree attains a good size, averaging from 4 to 8 feet in girth, and from 10 to 30 feet in height.

Mr. Graham Anderson, of the South Mysore Planters' Association, has contributed a valuable memorandum on the Silk-Cotton trees of Mysore, which we quote below in its entirety; as Mr. Anderson says that the trees indigenous to Mysore have engaged a large share of his attention for many

years, and therefore the following remarks by him are most valuable :—

The Superintendent of Government Gardens in Bangalore deserves the thanks of the agricultural community for the attention which he has drawn to the subject of silk cotton, and it is earnestly to be hoped that in the future he will further assist by making public any information of a similar nature regarding other products which may appear to him worthy of introduction or cultivation, it being impossible to over-estimate the benefits which the department over which he presides is capable of bestowing on the Province generally. As I have personally no pretensions to technical knowledge, I am not at all sure that I have correctly identified the kapok tree, but I most diffidently venture to make a few remarks on the silk-cotton-producing trees of Mysore, and to refer specially to one which in my humble opinion most closely answers to the description so obligingly afforded.

Among the varieties of the order *Sterculiaceæ* to be found in our Malnad, I failed entirely to recognize the *Eriodendron anfractuosum*, and have consequently made some careful inquiries about it.

My remarks, I trust, may be of some service even if they only lead to prove that more yet remains to be learnt regarding the tree, both as to its identity and the possibility of extending its cultivation.

Bentley divides the order *Sterculiaceæ* into three tribes :—

Bombaceæ.—Examples; *Adansonia*, *Eriodendron*, *Bombax*, *Choristocarpus*, *Durio*, *Ochroma*, &c.

Helioterææ.—Examples; *Matisia*, *Helicteres*, &c.

Sterculiææ.—Examples; *Sterculia*, *Heritiera*, &c.

Lindley enumerates 37 genera and 123 species as belonging to this order. (Bentley.)

The plants of interest are referred to as follows :—

Chorisia speciosa.—Has its seeds covered with silky hairs which are used for stuffing cushions, &c. It is termed vegetable silk.

Eriodendron Bauxiana.—South America; remarkable for its great height. The hairy covering of the seeds of various species of *Eriodendron* is employed for stuffing cushions, &c.

Bombax Odiba.—The silk cotton tree of South America.

Bombax Pentadactylon.—The silk cotton tree of India. The seeds of these are covered with long silky hairs. These hairs cannot be used like those of ordinary cotton for manufacturing purposes, chiefly on account of the smoothness and want of adhesion between their sides. (Bentley.)

(3672) The wool of several species of *Eriodendron* and *Chorisia* is used for stuffing beds and cushions, and that of *Ochroma lagopus* substituted for beaver. (Page 919. Outline printed by I. and C. Adlard).

In the Malnad the varieties of *Bombax* are as follows :—

Mulburaga (Canarese) (*Bombax heptaphyllum* or *pentadactylon* (?)) large, very thorny deciduous tree with a red flower. Yields very inferior silk-cotton which cannot be twisted into a thread, the fibre being very brittle; grows in the Malnad Forests.

Buraga, *Bilburaga*.—Canarese.

A somewhat smaller, deciduous tree with a white flower. Hardly any thorns at all. Yields a somewhat better cotton which can only be used for stuffing purposes. Grows on the edge of the open country to the east, but is very rarely found in the Malnad. The bark is said to be used by the natives for intestinal disorders of cattle.

The cotton escapes from the pod about February-March, and is very difficult to collect owing to the strong east wind which then prevails. The thorns of the *Mulburaga* offer an insuperable difficulty to gathering of produce.

As the wool of the *Eriodendron* (*Erian*—wool, *Dendron*—tree, Greek) is explained to have been spun into yarn and made into articles which have been submitted to the Colonial Museum at Haarlem, and is further described as being used for tinder, I immediately concluded that our *Bilburaga* was not the tree referred to, and consequently directed my inquiries to the eastward with the result that I found a tree known as the *Duli Mara* (Canarese, the *Tinder tree*) (Yellam panji, Tamil), in Hassan. This tree is propagated both from seed and trunk cuttings, and is used in the sugar gardens for growing the *betel-leaf creeper* upon.

The silky wool of this tree is certainly very superior to the produce of any of the *Buraga*, and *Bilburaga*, as I regret to say, quite escaped my observation.

The sample herewith sent, together with one of the pods, will suffice for identification.

Should this tree be the kapok, the knowledge that the produce is a marketable commodity will go far to at once induce owners to carefully collect it.

I should imagine that all well-drained good soils would be suitable for the growth of the *dadi tree*, and all jungle lands would answer admirably.

The tree is however not one that would stand wind and being deciduous, would not do for shade for coffee. I am doubtful as to whether the crop would be one which would be remuneratively gathered in the wet climate of the Malnad, as it appears to mature in June, or just at the beginning of the South-West monsoon.

The experiment is, however, well worthy of trial on a small scale on abandoned clearings and jungle scrub land.

In a strictly agricultural province like Mysore, an immense amount of good can be done by the introduction of new products, and I most sincerely hope that the skilled services of the Superintendent of the Government Gardens may be utilized in that direction, precisely in the same manner as in the Crown Colony of Ceylon and elsewhere.

The matter of exchange and introduction of seeds with foreign countries is an impossibility with private individuals, and the single fact that the *dudimara* has hitherto been almost wholly neglected, is a good example of the immense benefits which the talented Superintendent of the Government Gardens could confer on the agriculturist, if the requisite facilities and funds were placed at his disposal.

The silk-cotton gathered from these trees is known by the name of kapok. It is ready for harvesting in the beginning of summer, or in the months of February and March. When separated from the pod, and cleaned, the total amount of kapok received by the Mysore Government from the districts did not exceed 30 lbs., from which quantity an assortment of 22 lbs. was well cleaned, and equally divided for valuation in London and Rotterdam. In Holland the kapok has a somewhat extended trade; but it appears that the article imported from Java is of a somewhat superior kind. This is, however, not the product of the *Eriodendron* or any of the silk-cotton trees, but of the *Calotropis Gigantea*, or *Madar*. Messrs. Collyer and Co., Brokers, of London, to whom a sample of *Eriodendron* kapok was sent, made the following reply dated 6th February 1885 :—

We have received one case of *Sennil Cotton* per S. S. *Khadia* through Messrs. Arbuthnot and Co., Madras.

There is but little demand for this material for home consumption, but large trade is done in it between Holland and the Dutch East Indies, the quality of the latter being preferred owing to its greater length and lightness. Your sample is rather short, fairly but not quite well cleaned, nominal value about 50s. per cwt., and would sell for export in considerable quantities.

For home use a somewhat similar material is wanted, small sample enclosed; we should be glad to receive samples of what you can offer, and lowest price you can supply specified quantities at freight paid to London, the extent of the demand will depend upon the quantity obtainable at low prices, say 5s. to 6s. per lb. net weight. Please state clearly what quantity you can sell and in what months it could be sent forward, and total quantity available if collection is worth attention.

They followed up this letter by another, dated 13th February, saying :

We confirm our report of 6th instant. It is uncertain how far a material reduction in price will stimulate consumption, the stock in Holland is large, say 2 to 3,000 cwt. or more, the average price for good clean quality is there 70 to 90 per cwt., the value put upon your sample in Amsterdam was 47 to 55 per cwt. Our manufacturers of down quilts, &c., will not admit kapok into their factories, preferring to maintain their high standard of quality by using actual feather down. Probably new uses may be found if the material becomes plentiful and cheap. As indicated in our last, a demand is arising for long stapled varieties. We sent one sample last week; we enclose another even more wanted which appears to be "Sennil;" this would sell freely at 5s. to 6s. per lb. for a special purpose.

Any further samples you can send us shall have our best attention not only of "Sennil," but of any new variety of fibre or other products.

The reply from the Rotterdam tradesman (J. O. Kistner), dated 24th February, was as follows :—

I feel much obliged for the pains you took in addressing me the case containing kapok from your forests, and which you submitted me by your favor of 20th January 1885.

I received that case in most perfect order, and I am pleased to declare that this quality of kapok is not inferior to that from Java.

Perhaps it might interest you to hear that kapok cleaned in this manner, now is sold 55. per 4 kds or 44d. per English lb. (English currency standing) free in the harbour of Rotterdam.

The foregoing reports are, of course, favourable as regards the quality and condition of the samples submitted for valuation; but the prices offered are considered so low, that the Mysore Government do not think it expedient to take any further steps to advance this industry. The sample sent by Collyer and Co. was found to be the seed cotton of the *Calotropis gigantea* which, as we have said before, is about the commonest weed to be found on the plains of India.

INDIAN STATISTICS.

There is probably no country in the world in which statistical researches are so crudely pursued as in India. Too often the figures fall into the hands of men who have some pet theory or conclusion to establish, with the result of making them prove almost anything that is desired. It is impossible to give five minutes' attention to the resolution in the *Calcutta Gazette* of the 23rd September, on the Medical Institutions of this city, without seeing at once how this habit has warped all its conclusions. Thus we find the mortality from small-pox in the city in the last ten years, to have been as follows:—

	Per Mille.		Per Mille.
1876 ...	720	1880 ...	114
1878 ...	71	1881 ...	123
1877 ...	87	1882 ...	17
1879 ...	1,495	1883 ...	78
1879 ...	772	1884 ...	478
Average ...	625	Average ...	162

Now one would reasonably suppose that it lies upon the very surface of these figures—which we have simply re-adjusted to show their teaching—that the mortality from this disease in any given year, arises from its assuming now and again, an epidemic form. If the figures prove anything, they prove we say that the high mortality that takes place in some years, as in 1875, 1878-9, and 1884, is the ordinary and unavoidable result of the disease assuming an epidemic form. The very low mortality in other years, indeed its almost total disappearance, shows on the other hand that the normal condition of the city must be held to be satisfactory. This conclusion lies we say, on the very face of the figures, but as it is the settled purpose of the Executive Government to throw blame and discredit upon the Municipality, the fact that the disease assumed an epidemic form last year, leaves "no doubt"—observe the phraseology—in the mind of the Inspector-General that these 478 deaths in 1884 show "the need of far greater activity on the part of those whose duty it is to protect the people." That the average mortality during the last five years was but 162 deaths per year against an average of 625 in the previous five years, would lend any candid mind to the inference that great, and unusual, and successful efforts have been made to protect the people: but as that is a conclusion that the Government does not want to admit, the figures are boldly used to suggest an entirely opposite belief. The most crucial test we can apply to the health of any city in India, is the mortality from fever therein. Let the reader then observe the following figures as adjusted by ourselves:—

	Per Mille.		Per Mille.
1876 ...	5,328	1880 ...	3,797
1878 ...	4,361	1881 ...	3,785
1877 ...	5,151	1882 ...	5,018
1879 ...	6,086	1883 ...	3,442
1879 ...	4,796	1884 ...	3,618
Average of 5 years ...	5,145	Average ...	3,648

Here again, if the figures prove anything, they prove that a singularly gratifying success has attended the labours of the Municipality to improve the sanitary condition of the town. As a fact, it is these statistics concerning fever, that constitute the very heart of the enquiry, and because they establish in the most absolute manner, the vital improvement that has taken place in the sanitary condition of the city—the Secretary, for we do not like to lay the blame upon the Lieutenant-Governor personally,—the Secretary to Government passes them over in dead silence. The Lieutenant-Governor, must see that they show

the hollowiness of the outcry got up against the Commissioners, while the public can now see the *insincerity*, as well as the hollowiness, of the cry.

Every one knows that cholera and small-pox are capricious in their appearance, and that cholera in particular is so mysterious in its affinities, that it is impossible to affirm with any certainty the specific causes of its outbreak. The disease that is largely under control is fever, and because its statistics disprove and dispose of the attacks made on the Municipality, the Lieutenant-Governor is silent about them altogether. This is not the way for a ruler to earn the respect, or confidence of the ruled. We invite the attention of Lord Dufferin to this brief note, and we suggest that he should ask Mr. Mackenzie to reconcile it with the despatch that he made the Viceroy sign, a month ago, on the merits of the Commissioners.

THE FLOODS.

GOVERNMENTAL MEASURES.

THE rains have been very heavy in the last few days, coming in cyclonic bursts that fortunately do not last very long, but that are very violent for the time. From a letter issued recently from the Revenue Department, to the Commissioner of the Presidency division, we learn as to Jessore, that—

A large tract of the country, estimated at about 360 square miles in the Bongong sub-division of Jessore, has been inundated by the river Ichamati and its tributaries overflowing their banks. A large proportion of the *aus* crop appears to have been saved, but there is reason to believe that the *aman* rice has been almost entirely destroyed. Only one life appears to have been lost, but the people are undergoing much discomfort and hardship. No actual distress is reported; rice is selling cheap in the flooded tract, and some shop-keepers who went out with food from Jessore found difficulty in disposing of their stocks.

Until the flood-water has drained off, the Government finds that it can do nothing beyond dealing with emergent cases of individual distress. For this purpose, the Collector is authorised to expend Rs. 500 on petty relief, and the Lieutenant-Governor has sanctioned the expenditure of a further sum of Rs. 1,000 pending the introduction of systematic relief measures, should that be necessary. In the distribution of this amount, the assistance of private persons, missionaries, and others who are specially acquainted with the wants of the people, is to be enlisted.

In the event of relief measures being deemed necessary, definite proposals should be submitted for works to be undertaken from Road Cess or Provincial funds, for small advances under the Agricultural Loans Act, and for loans of larger sums under the Land Improvement Loans Act. Grants under these three heads will, the Lieutenant-Governor believes, probably be found sufficient to meet the needs of the bulk of the distressed population; while in cases of individual distress, the Government may hope that some assistance will be derived from private charity.

As to Nuddea, the flooded area comprises two tracts of country, which have been affected by the inundation caused by the bursting of an embankment on the *Bhagiratha*, aided by the excessive rainfall. The northern tract of flood comprises Khoosta and Chocadanga and part of Meherpore, but no very serious damage appears to have been done. In the southern tract unfortunately, "the aspect of things is more gloomy. Only a small proportion of the *aus* crop appears to have been harvested, and it is feared that much of that has been destroyed by the floods overtopping the village threshing floors, and of the *aman* crop no portion is likely to be saved."

It follows from these facts, that in the northern tract the class of landless day-labourers will suffer to some extent from want of the work with which the rice harvest ordinarily supplies them; while in the southern tract pressure will be felt by both the cultivating and the labouring classes. To the labouring class in both tracts, relief can most suitably be given by opening works at carefully selected centres, and I am to accord formal sanction to the expenditure of Rs. 5,000 in the District of Nuddea on this account. Sir Rivers Thompson hopes, however, that the magnificent harvests which are expected everywhere outside the flooded area, will draw off the surplus labouring population of this part of the country. This is the *most* desirable as the collection of labourers upon works in a country recently flooded, is not unlikely to result in a serious outbreak of disease. For the cultivating classes, it seems likely that no relief measures will be necessary, and that they will be enabled to tide over the period which must intervene before the *aman* crop can be reaped by a judicious distribution of advances under the Agricultural Loans Act. For this purpose the Lieutenant-Governor sanctions the expenditure of Rs. 10,000 in Nuddea. Special

measures should be taken to facilitate the distribution of advances by the sub-divisional officers, and to make it generally known that Government is prepared to offer this assistance towards the cultivation of the rubber crop.

These measures seem at present to the Lieutenant-Governor, to meet the necessities of the general mass of the population, although individual cases will probably occur, in which gratuitous relief will be needed, and for this relief the Collector of Nuzvid is seeking the assistance of zemindars and others.

The Lieutenant-Governor has no doubt that private liberality will do much in this direction, particularly in the way of assisting people to rebuild the large number of houses destroyed by the floods. In the meantime, and until private charity has been fully organized, I am to convey sanction to the expenditure of Rs. 100 on relieving persons who are incapable of work. I am to add that the distribution of this sum may properly be entrusted to private individuals, missionaries, and others who are intimately acquainted with the wants of the people in the flooded tracts.

Regular reports of the condition of the people are to be carefully submitted, and the Lieutenant-Governor himself left Calcutta a few days ago, to visit the districts.

Miscellaneous Items.

The coffee crop of the current season in Ceylon is expected to be a late one, owing to the spring rains having been deferred. It is likely to be the same on the Nilgiris, both from the cause stated above, and from the crops of 1884-85, having been on the trees as late as April and May, and from the planters not being in a position to strip at the usual time.

A deposit of sulphur was lately accidentally discovered in the Nersapur taluk in Godavari. In digging on a piece of waste land, some earth was turned up, the peculiar appearance of which attracted the attention of one of the passers-by, the village magistrate, who, having secured a small quantity of it, forwarded it to the Civil Surgeon. A rough analysis of the earth disclosed that it was strongly impregnated with sulphur, and a further examination of the locality in which it was found resulted in the discovery that the deposit extended over a considerable area.

A TELEGRAM to a Madras paper says that the want of rain is generally felt by the ryots of the Mysore district. Hardly any fields beyond Chikmagalur on the Mysore Railway line have been sown, and prices of rice and ragi are ranging high. The Mysore country beyond Mysore looks barren. Great anxiety is felt in regard to the season prospects.—Mr. Girdlestone, British Resident, proceeds to Mysore on the 1st proximo for the Dassera festivities, and the Maharajah and the Dewan will then consult him as to the organization of the necessary relief measures. The weather here is pleasant.

THE *Bombay Gazette* says:—As there has been a good deal of conjecture here as well as in England, about the ultimate success of the Indian Village, we have obtained a list of the people engaged to go to England, with their particular work and the rate of pay. We see in the list a snake-charmer, a dancing-girl, and our old friend the inland-box worker. The rate of salary is very fair, almost verging on liberality. Mr. Bonner, the agent who had come out to India to organize the movement, acknowledges the services of Mr. De Vitre for the assistance rendered in procuring the different workmen. Mr. Bonner states that Mr. De Vitre's tact in overcoming the obstacle of caste prejudices was remarkable. It should be added that Francis Kobbé and Jerome Kobbé and three Mahomedan weavers left Bombay for England to represent some of the industries of Tannah at the Indian Village Bazaar. The Kobbés will exhibit the well-known hand-made silk, and the weavers the equally well-known Tannah cloth.

Selections.

CINCHONA HARVESTING.

A SUBJECT which has been much discussed amongst planters, without its ever arriving at a satisfactory conclusion, is that of the best method of working cinchona trees. Hitherto the area under yielding trees has been comparatively small, and isolated planters have been engaged to try one system or another with varying results. But millions of plants have been put out within the last four or five years in this presidency, and will soon be fit to bark, so it is of great importance that the matter should be enquired into, and an authoritative decision, if possible, be made on question. We may say, at the outset, that we are not in a

position to give such a decision. All that we propose to do is to indicate the lines on which such an enquiry should proceed.

There are three systems of taking the bark more or less in vogue, namely, stripping, shaving, and coppicing. The first of these has, we believe, not been generally found to answer. It consists in removing a long strip of bark down to the wood, and then covering up the part to allow it to renew; but the bark very often refuses to renew under this treatment, and the tree is permanently damaged, if not entirely destroyed. Shaving is the process most usually adopted, and it has one advantage, at least, over coppicing, viz., that the proprietor gets a small revenue each year after the fourth, instead of having to wait till the seventh or eighth, and possibly, losing his tree by canker in the interval. It may be done with the ordinary pruning-knife, which many planters maintain is the best instrument for the purpose, or with specially-made spoke shaves, or with a Ceylon invention, called a box-scaper. This last answers very well for original bark, but, as at present made, will not remove the thick or renewed bark; it is also rather expensive. After shaving, the tree is usually covered with grass. The rival methods of shaving and coppicing have both advocates who insist on the superiority of their own plan, and it is difficult to decide between them. A few years ago, when "druggists' quill" was worth four shillings a pound, a man who could cut down a few thousand well-grown trees made a small fortune. Unluckily there were very few who could do so. The demand for this variety—apparently only to be used as an ornament in druggists' shop windows—seems now almost to have died out; for while the enormous Ceylon export has lowered the price of every kind of bark, the fall in quill is greatest of all. Shavings, which were worth half a crown or three shillings a pound, are now down to eighteen pence, but the quotations for quill have sunk even lower. While, too, it is evident that the Ceylon supply of bark is gradually becoming exhausted, and that the market for ordinary kinds is improving, it seems questionable if quill will be again in great demand. Still, if we take the present market rates as a guide, the pecuniary advantages of the two processes appear to be pretty evenly balanced. The question as to whether the tree is checked in its growth or not by continued shaving may be left out of the present calculation; it seems agreed that, if the operation is carefully performed at the proper season, not much harm is done.

The following are approximately the respective revenues that would be derived from shaving or coppicing a fair specimen of cinchona succulubra by the seventh year, three annual shavings being about what an average tree will stand, though it is sometimes carried on longer. Shaving four years (original) 8d.; five years (renewed) 10d.; six years (renewed) 10d.; seven years, cutting down 4s.; total 6s. 2d. Coppicing at seven years, quill say 3 lbs., 4s. sundry (branch etc.) 3 lbs. (at 9d) 2s. 3d.; total 6s. 3d. The above estimates are, it will be understood, only such as can be made from data accessible to the ordinary cultivator, and are therefore open to correction; planters, as a rule, have had to work very much in the dark in this matter. Only one establishment in India—or indeed in the world—could, if it wished, give us full statistics on the subject. But useful as such statistics would be to the whole body of cinchona growers, the authorities at the Nedivuttum Government Gardens prefer to keep them from the light of day. They go on flooding the market with bark, curing, and from all accounts knowing little whether the sales show a profit or a loss, but they steadily withhold information. Recent occurrences have shown that figures are not the strong point of the Superintendent of the Government Gardens, but should he ever publish the results of his experience, we would suggest the following as a sample of those questions about cinchona cultivation that urgently need replying to. What is the relative mortality in trees shaved from, say, their fourth year, and those left intact for coppicing? What are the relative profits of the same on a given area? What measures (if he has tried any) have increased the alkaloids and the growth of the tree? Has he discovered any prophylactic against canker, or any cure for it when once it has set in? We could increase the list considerably if we thought there was much prospect of any answers being elicited. This is one of the things they manage better in Ceylon, for Dr. Trimon, of the Royal Botanic Gardens, is always ready to supply information to the public. He has not, however, the unrivalled opportunities of his Madras colleague on this subject. We may here draw attention to a paper by Mr. Hamilton, in a recent number of the *Tropical Agriculturist*, on the preparation of bark for the London Market. As a member of a firm of produce brokers his opinion should carry some weight, and he thinks that sufficient care is not taken with curing, sorting, and packing the different varieties. A great deal of rubbish is also sent home, which really does not pay its expenses. Twig bark, for instance, has been selling for about a penny a pound lately, and as it does not cost much less than an anna to land, there is bound to be a loss on it. To be worth harvesting it should be sold locally, and the establishment of a manufactory at Calicut, such as was lately proposed, would be a great benefit to planters.

As to the general prospect of cinchona growers in India, we believe them to be hopeful. The Ceylon men have set down immense quantities to help them with their tea extensions, and as far as we can learn, are not repenting; the South American bark has almost ceased to be exported; the Java production is certainly not increasing, and it seems as if the industry was not going to be a success there. A powerful Association has, as we recorded some weeks back, been formed in the States to drive English and German made quinine out of the country. Its members have determined to manufacture extensively, and to undersell the foreign product, even if they have to work at a loss for a time. Of course, they are dying in the face of colossal competition, but they are bound to have bark, and, at the present supply in the States, they are sufficient for current requirements, prices ought to rise. *Madras Mail*

THE SWEDISH METHOD OF BUTTER MAKING, OR HOW SWEDISH EXPORT BUTTER IS MADE.

[Prepared by a Professor of Agriculture in one of the Swedish Colleges.]

CLEANLINESS.

One absolute condition of obtaining good butter is that the greatest care be taken to preserve cleanliness, both in the milking and during the whole operation with the milk and butter. This also applies to the vessels and utensils that are used in the dairy.

THE FODDER.

The fodder that is given the animal must be fresh and good, if rape seed cakes (*rapskakor*) (at the most one and a half pounds per day to each animal), bran or oats, bolted; these tend to increase the fever and fine quality of water butter.

THE QUALITY OF THE MILK.

The milk that is to be used in the dairy must not be mixed with that from sick cows or dry cows; and the milk should not be used in the dairy until the sixth or seventh day after calving.

THE MILKING.

At the milking, care must be taken that the udder is well wiped with a dry towel, and that the milkers have perfectly clean hands; also that these do not dip in or come into any contact with the milk. Duging must not be undertaken during the milking.

THE TREATMENT OF THE MILK BEFORE SKIMMING.

The milk must be removed from the place as soon as possible, and in the summer be exposed as little as possible to the heat of the sun. Directly after the milking it should be strained through a close linen cloth, or still better, a fine wire sieve. When the milk has come into the dairy, it is best if it can be separated immediately, for the sooner this is done the better, and the butter will keep longer. If it is not possible to do this, and should the milk, from some cause or other, have to stand for some time before the separation occurs, the place in which the milk is kept ought to be well ventilated, so that good and fresh, as well as dry air, prevails there; this also holds good throughout the dairy. The ventilation is to be secured by means of large ventilators, both at the floor and roof. During the warm season of the year, if the milk is kept 12 hours or more before the separation can take place, it ought to be cooled in water or ice. If the temperature of the milk has for some cause or other gone down below 77 degrees, the milk, directly before the separation, should be heated to 77 degrees Fahrenheit. Immediately after the separation, the cream should be cooled, in ice by preference. The more thoroughly the cream is cooled, the finer will be the butter and the longer will it keep.

THE SOURING OF THE CREAM.

Eighteen or twenty hours before the churning, the cream must be heated to 60 or 70 degrees; in the winter higher, in the summer lower; poured into the (*graddunnan*) cream vessel, and set with 2 to 5 per cent buttermilk or sour cream, from a previous churning. One regulates the degrees of temperature and the souring ingredients (*syrtilsättning*) so that the cream directly before the churning has its right sourness. In order, during the whole souring time, to keep the temperature somewhat equal in the cream vessel, one surrounds it in the winter with straw or the like, for the temperature in the cream barrel must never sink below the churning temperature, and neither is it well to heat the cream above 74 degrees. For the heating of the cream one puts it in tin pans (*bleckkanor*), in water of 105 degrees, not higher, and stirs (*rorer*) it constantly until the cream has reached the right temperature for souring. This can also be accomplished with a so-called cream warmer of tin, which, filled with water of 105 or 120 degrees, is moved around in the cream until it attains the proper temperature.

The greatest attention ought to be given to the cleansing of the cream barrel, and it ought always after every souring to be extremely well scalded with boiling water or steam, as well as to be well aired and dry before use, otherwise the butter will get a tang (*blomsk*). It is, therefore, most suitable for one to have two cream kegs, and use each every other day. In order to keep the curds (*syran*) constantly fresh, one prepares them at the farthest once or twice a month, and, for the rest, immediately, if any remark has been made against the butter, for with the old curds (*syran*) the defect is transferred from one churning to the other. New curds (*syran*) are prepared in the following way. Twenty pounds fresh milk are heated to 95 degrees Fahrenheit, and kept in a stone jug, which is placed in a box or the like, filled with hay and covered with a lid, so that the temperature is maintained; after four hours, when the milk is generally already sour, it is well stirred, so that all the cream that has formed is mixed in, after which one allows it to stand twelve or fourteen hours longer, during which one now and then stirs the milk vigorously so that no lumps are formed; then the curds (*syran*) are ready for use. Should they not be used immediately, they must be kept in ice water. This quantity of curds is sufficient for the souring of 400 or 500 pounds of cream. During the first three hours of the souring one stirs the cream a few times. But afterwards it must stand untouched until a half-hour before the churning, when it must be thoroughly stirred. Through this it obtains an extremely sour taste. It is better to have it rather too strong than too weak, for otherwise the butter will acquire a flat and, most frequently, a bitter taste.

Then the cream is cooled to 50 or 60 degrees higher in the winter, lower in the summer, and then strained in the churn, which has before been placed in water of a corresponding

temperature. The best churns are the so-called Holstein. The churn, ought not to be filled more than half or two-thirds full of cream. Before the churning begins a suitable quantity of coloring matter is put in the churn, so that the butter gets a faint tinge of straw-color. One must take care in the pouring in, that the coloring matter does not come to the worst in the churn, as the color would then easily become uneven. The coloring matter must always be regulated by the quantity of milk from which the cream has been obtained, and a suitable coloring ingredient is 2.5 to 5 grains for 100 kilos of milk, that is, 35 to 70 grains per 200 pounds according to the season of the year, and the demands of the market. Then it is churned with such speed that butter is obtained in from thirty to forty-five minutes, and this is regulated by the temperature and the speed of the churning: high temperature and quick motion yield butter soon, a low temperature and slow motion the contrary.

When the cream has returned, the churning is interrupted for a few seconds, and the cream that has dashed up on the lid and sides of the churn is rinsed down with water or skim-milk of the same temperature as that which prevails in the churn. Then it is churned more slowly, in order to get the small flakes or pellets of butter to collect, and now it is of great importance that the churning is stopped in the right time. If one breaks off too early, less is obtained, and if one churns too long, the butter becomes overdone. When the buttermilk separates itself, clear, from the pellets of butter, and these are so close the size of a pin-head and have a rough surface, it is time to stop.

The greatest care ought always to be devoted to the cleaning of the churn; it should be carefully rinsed every day with boiling water, and afterwards aired and well dried in the open air. Churns that are not perfectly dry often give the butter an old taste. If one can steam the churn once a week, this is particularly suitable.

The butter, when ready, is taken out of the churn with a hair-cloth sieve, washed in one or two waters, whereupon the buttermilk is pressed out through working over with the hands. Then the butter is weighed and mixed with 2 or 3 per cent of good salt, the best Lunningburger, which is kneaded in with the hands. In working over with the hands, the butter must never be rubbed, but only pressed. Then the butter must lie one or more hours, until it has got some firmness, then it is worked over in a kneading machine, or on a kneading board. In the summer it is suitable to let the butter, before the last working over, lie in a so-called refrigerator, through which it obtains greater solidity. The refrigerator is made of beech wood, 14 inches high, 20 inches wide, and sufficiently long to contain the butter desired. The butter is laid on a wooden trawl (*transvaller*), 1 inch thick, 2 inches broad, that is placed across the bottom of the box on cross pieces on the long side one inch from the bottom. The box is also covered with a lid, which consists of a box three or four inches high, of zinc, in which pieces of ice can be laid. In the ice-box, or refrigerator, the butter lies in cold air, and, through this, acquires still greater solidity.

THE PACKING OF THE BUTTER.

As soon as the butter is ready, it is put in firkins, in which it is packed down closely with a wooden pestle, so that no apertures are left in the butter. When the firkins are full, the surface is smoothed with a wooden spade, covered with oil-cloth and strewn with a layer of fine salt one-half inch thick. The firkin is well rinsed with water before use, rubbed on the sides and bottom with salt, and kept as clean and white outside as possible. The whiter and more sweet the firkin is the more desirable the butter in the market. Firkins of red beech are, on this account, unsuitable. On the lid of the firkins must be placed the trade mark of the dairy.—*Farmers' Review.*

THE MOREL.

It may interest the readers of the *Indian Forester*, who are fortunate enough to possess fine palates, to know that the morel (*Morchella esculenta*), an edible fungus which rivals the truffle in delicacy of flavor, is common in Jaunsar, and was found by me in abundance in May last in that portion of the Dehra Gadh desher forest belonging to the Keonjhar State, which suffered so severely from fire last year. The paharis set great value on it, and eagerly gather all they can find.

The following is the account of this fungus in the *Treasury for Botany*, where a good illustration of the plant is given:—

"Morel is the common name of *Morchella esculenta*, which, under a variety of forms, occurs in various parts of the world. It is occasionally plentiful in this country, but the greater part of what is sold by the natives comes from Germany. A large quantity is collected in Cashmere. As it dries very readily, and may be kept for some time, it is much used by cooks to flavor gravies. It is also dressed in various ways when fresh, and makes an excellent dish if stuffed with finely minced white meat. When plentiful it may be advantageously employed instead of mushrooms to make kedgeree. Morels are particularly fond of burnt soil, and the collection of them is so profitable to the peasants in Germany that they were formerly in the habit of setting fire to the woods to encourage their growth, till the practice was made punishable by a special law. *M. esculenta* may be known from the common morel by the border being quite free for some distance. It has a bad reputation, and requires, therefore, some caution in its use. The genus *Morchella* is distinguished by a deeply pitted naked head supported on a peduncle. The depressions are sometimes regular, but occasionally they assume the appearance of mere furrows with wrinkles like interstices."

N. HARRIS.

(*Indian Forester.*)

PLANTING ENTERPRISE IN JOHORE— EUROPEAN AND NATIVE.

WHEN Mr. Hole, private secretary to the Maharaja of Johore, passed through Colombo on his way to this country with his Highness, he was interviewed by a reporter from one of the local papers, and in due course publicity was given to what purported to be his opinions regarding the past, present, and future of Johore. The European planters on the Pulai range have always acknowledged the encouragement and substantial help afforded to them by the Maharaja, but they were hardly prepared to find his private secretary announcing to the world that hitherto European enterprise had been practically a failure so far as the planters are concerned, and a source of loss instead of profit to his Highness. One of them takes up the cudgels on behalf of his class, and writes as follows:—“It is true enough that coffee Arabica, of which Mr. Watson was the pioneer, has proved a failure, but Liberian coffee has taken its place, and will ere long more than recoup all the losses incurred on the other. No one has done more towards bringing this about than Mr. Watson has, and at the present time no one has a larger stake in the planting enterprise in Johore. While the Maharaja has given every encouragement to the European planters, he has given equal, if not greater, facilities to the Chinese gambler and pepper planters, who, while they saved the revenue of the country by the taxes on gambler, pepper and opium, on the other hand are doing incalculable damage by the indiscriminate manner in which they carry on the cultivation. For miles on every side of Johore Bahru there is little or no forest to be seen now, where some twenty or thirty years ago there was nothing but heavy valuable timber. Now there is nothing but long stretches ofalang grass, with patches of scrub and a few strips of jungle near the few gambler and pepper gardens left in this locality. Now all this is caused by the gambler and pepper cultivators who made off to fresh land further afield as soon as they found their gardens falling off in yield, instead of applying manure. From the top of any hill you will see innumerable park like glades which are very pleasing to the eye at a distance, but on closer inspection they turn out to be cultivated and abandoned gambler and pepper gardens, the abandoned ones being overgrown withalang grass and are in proportion of at least 2 to 1 of those in cultivation. To be able to understand how this state of things comes out, I will enable you to understand how this state of things comes out, I will try and explain the system pursued by the Chinese gambler and pepper planters. When a Chinaman wants to open a garden he generally goes off to one of his countrymen in Johore or Singapore, enters into an agreement with him to the effect that the merchant advances money, food and opium to the planter from time to time, taking good care not to let his advances exceed, say, two-thirds the value of the garden. The planter for his part has to sell all the produce of his garden to the merchant at a fixed rate, which rate is always considerably below the real market value. You can, therefore, understand that the profits of the merchant are enormous, and that the planter is generally in debt. The gardens, as a rule, are from 8 to 10 acres, which are planted in the following proportions, viz., about 4 or 2 acres of pepper vines and the proportions with gambler. The forest is felled and burned off as for coffee, the place intended for pepper is dug up and prepared most carefully, pepper cuttings planted about 8 feet apart, and a jungle post about 10 feet high sunk in the ground beside each plant, to which it is eventually trained. The balance of the clearing has very small holes cut about 6 feet apart in which young gambler plants are put and left to fight it out with thealang grass, ferns, and other weeds, which soon out with thealang grass. In eighteen months from planting the gambler gives a return which helps the planter to pull along till his 1,000 or 2,000 pepper vines begin to give crop when 3 years old. On each side of a gambler and pepper garden there is a reserve of forest 8 chains wide, in which he has the right of cutting any timber he may want for posts for his vines, firewood for boiling down his gambler, or for making burned earth, which, with the refuse from the gambler boilers, is the only manure applied to the pepper vines when the garden is any distance from a gambler town. If a little more care was given to the gambler, there can be no doubt that, not only would the returns be greater, but the garden would last much longer—the gambler being generally worn out long before the pepper begins to fail. As soon as the planter finds that the pepper is giving out, he looks about him for another piece of forest and starts afresh. If this kind of cultivation is allowed to grow unchecked it is only a question of time, and that of no great length, before the whole of the valuable forest in this country will be destroyed. The rise in price of pepper some months ago has given a great impetus to the opening up of gardens.

“The only remedy I can see to stop the destruction of so much valuable timber would be to try and induce the planters to grow these pepper vines on trees planted for the purpose, such as dadap, cotton tree, &c., and they might also be bound down to cultivate their gambler, at least to the extent of keeping out thealang grass, and if the land was to be abandoned, the planter should be bound to plant a certain quantity of forest trees on it. It is a well-known fact that pepper grown on live trees, such as dadap and cotton is much more lasting, costs less in cultivation, and gives more crop than it does grown on the jungle posts; and that the gambler would be all the better for a little more cultivation is also certain. When land has been ‘‘chopped’’ in Ceylon it certainly deteriorates; but not to the same extent as the land here after gambler and pepper has been grown on it. In the former case ‘‘cheddy’’ soon grows up and eventually jungle trees, but when thealang grass once gets hold of the land, nothing will grow in conjunction with it.

“I am glad to see Mr. Hole spoke favourably of tea in Johore. The gentleman who is carrying out the experiment of making

Oolong tea in the Formosan fashion for the American market has just brought down some more men from Amoy, also boxes, lead, paper, and in fact everything required to start out as similar to the above. As soon as Indian labour is available, however, I fancy he will revert to the Indian method, as there is no comparison between the cost of preparation with Tamil and Chinese. Indian labour will be available very soon now, as the labour question is virtually settled, and Johore will be able to get Indian labour on the same terms as Singapore and the protected native States. Mr. Hole would have been more correct had he said that the construction of a railway was contemplated. So far only a single track has been made for about 10 miles out of Johore Bahru in the direction of Gunong Pulai. If the proposed railway is made, it will open up a most valuable tract of country for planting purposes, and at the same time the splendid timber will be made available.

—*Planters' Gazette English (Paper).*

ANTS ON TREES AND PLANTS.

THE ants so often found in great numbers upon plants and young fruit trees cause no injury. Their presence is due to plant lice, a very peculiar insect found upon nearly every part of plants, but usually in the greatest numbers upon young shoots, buds, and leaves. These parasites multiply with wonderful rapidity. It has been proved by Raumer that a single individual is capable of becoming the progenitor of nearly six thousand millions of these pests in five generations. This accounts for the fact that the tender twigs and leaves of plants and small trees will often become completely covered with a living mass of these minute lice in a very short space of time. Most of these are females, but a few males are also present. The winged individuals, according to Harris, “appear only at particular seasons, usually in the autumn, but sometimes in the spring, these being all small males and larger females. After pairing, the latter lay their eggs upon or near the leaf buds of the plants upon which they live, and together with the males soon afterwards perish.” The genus to which plant lice belongs is called Aphis, from a Greek word signifying to exhaust. The eggs are hatched in the spring and the young lice immediately begin to exhaust the vitality of the plants by sucking the sap from the twigs and leaves. They increase rapidly in size and soon mature, and it is a remarkable fact that the entire brood, without a single exception, are wingless females and in condition to propagate their species. Their young, however, are produced alive, and each female may be the mother of fifteen or twenty young lice in a single day. The second generation also consists of wingless females, which grow up and have their young in due time, and thus brood after brood is produced to the seventh generation, or even more, without the appearance of a single male, but the last brood in autumn consists of males and females, upon which wings are developed, the eggs being laid by the females as before mentioned, and remaining upon the twigs until the following spring, when they are hatched and their work of destruction begins. The leaves and bark of plants much infested by these insects are often completely sprinkled over by a sticky, sweetish fluid discharged by them, which upon drying turns dark, greatly disfiguring the foliage. This sweetish fluid is what attracts the ants, which are very fond of sweets of all kinds. The ants are very careful not to injure or disturb the lice, which they treat with remarkable gentleness. Probably the most effective remedy for plant lice is strong soapwater, which can be applied in the same manner as for cankerworms by means of a garden pump. Some fruit growers use a decoction of tobacco with the soapwater, which makes the remedy much more effective. Care must be used not to make the solution so strong as to injure the plants. This can be determined by experimenting on a small scale. When the plants and trees are so low as to be within easy reach, the buds can be placed in a broad, deep dish, and the twigs bent down and immersed in them. Young fruit trees should be carefully watched this season of the year, and upon the first appearance of the lice means should be adopted to exterminate them before they have time to multiply extensively.—*American Cultivator.*

ARBOR DAY IN AMERICA.

THE practice of tree planting by private individuals, and associations has been taken up with much energy in the United States, and is likely to result in widespread public benefit. In Ohio, a State Forestry Association, which has been taken as a model for similar associations in other parts of the country, has been organized for the purpose of stimulating and developing public interest in arboriculture. The State Legislature has taken up the matter, and in 1883, a Government proclamation was issued setting apart the fourth Friday in April of every year as a public holiday, to be called Arbor Day, and to be devoted to the systematic planting of trees and groves in all suitable places. These measures have been rendered especially necessary in Ohio, where neglect and destruction of the forests have been allowed to continue for many years. It is intended that the State Forestry Association shall form the centre of forestry associations in every city, town, village and school in the State, whose object shall be to plant trees along streets, by the road sides, in parks and commons, around public buildings, and in waste places; to distribute information respecting trees and forest among the people, and to encourage tree planting in every possible way. The celebration of Arbor Day forms the subject of an interesting pamphlet issued by the Department of the Interior, Washington, in which is contained much information both practical and historical, and a valuable letter by the late Dr. T. B. Ketchum.—*Indian Forester.*

ELECTRIC SUGAR REFINING CO.

Summary of the report made by Mr. Wm. S. Levisson on the progress of the sugar treated at the demonstration of the process on the 1st July, and of the analysis of the raw sugar used.

1. He certifies the purchase of the sugar as—six tons Jamaica sugar from Messrs. Warner, Tobias & Co., on the 3rd June, which he had put into bags of about 100lbs, each for the convenience of handling. The description is known as Muscovado.

2. On the 9th July, 1885, he accompanied Mr. H. J. Abbot, United States Government Appraiser of Sugars for the Port of New York, and examined 120 of the said sugars, while Abbot took therefrom a fair average sample for analysis.

3. The sample analysed as follows—

Raw sugar	88 70
Invert sugar	3 30
Soluble ash	0 53
Insoluble ash	0 30
Organic matter	1 45
Water	5 70
	100 00

4. On the 13th July he took 84 bags of the 120, and delivered them at the house of Professor H. O. Friend. Prior to their being removed from store, they were weighed by a sworn weigher in lots of 10 each, and their total weight was 8,030lbs.

5. That after the demonstration he attended at the house of the said Friend and weighed the contents of 40 barrels of refined sugar, which stood in his dining room, and found that the aggregate net weight of the same was 6,663lbs.

6. That at the same time he weighed the bags of raw sugar which had not been used and also the empty bags, the contents of which had been refined, and he found the aggregate weight of all to be 880lbs.

From the foregoing statement it will be observed that the weight of the raw sugar taken to Friend's house was

8,030lbs.

From which deduct the amount left in bags and the weight of the empty bags

840 „

Leaves as the amount treated

7,190lbs.

The weight of the refined returned was

6,365 „

Consequently the loss was

565lbs.

Or a small fraction more than the amount of the saccharine matter which, per analysis, was shown to be in the raw sugar. The analysis shows—cane sugar 88 70 per cent, and invert sugar 3 30 per cent, or in all 92 per cent saccharine matter.

JAMES U. ROBERTSON

6, Baltic Buildings, Liverpool, 14th August 1885.

—Sugar Case.]

A BURMAN POSSIBILITY.

The subject of developing the mineral resources of the provinces has oftener than once been adverted to in these columns. The capabilities of the country place the desirability of such advancement beyond question. Practical suggestions and not theoretical investigations are what is most needed to secure the desideratum. The tin mines of Perak in course of a decade's systematic working under professional guidance or control have increased the public revenues of that "Protected" State, or appanage of the Crown, by over a million dollars; the income to the said exchequer being now nearly a million and a half dollars from this one source alone. But this growth of the Perak tin mining industry is not exceptional. The other protected states along the Malayan coast line have done, *pro rata*, equally as well; and even the Siamese dependency of Quaidab, which is contiguous with British territory, yields corresponding results. The success of the Dutch operations in Banca and Billiton in the same branch of metalliferous mining is without a parallel as regards European intervention in such industries in the East. The native working of the stanniferous deposits of Sumatra has also proved successful in being more profitable to the Sumatra Malay than the slower returns from precarious agriculture or other avocations. Under these circumstances we are at a loss to understand why the same department of industry should be an egregious failure in British Borneo. We are aware at the attempt made by a well known local firm to turn the Mergul tin deposits to good account. We are aware, also, of the causes that induced a negative result. Innovations are to be deprecated which neither suit the country nor conditions of working. Expensive machinery and highly paid establishments are not wanted in the nascent stages of any industry with the probabilities of success as yet unmeasured. The plan bound to operate best is that of utilizing indigenous resources to the furthest "Guidance" and not "change," is best suited to the temperament of the Asiatic laborer. Improvement in methods of working must be gradually effected under a process of time and example. The means and appliances should be within the ability and ken of those for whom they are intended. The way to meet the end is suggested in the word "encouragement," which can only be effected through professional skill and experience—to attract as well as to attract indigenous or imported labour. That is all which is required as technical knowledge. The Asiatic is susceptible of prompt action, and opportunity must be found for giving him the requisite ideas—some times by precept, and at other times by example, for the improvement of his rude system of working. He will be led, and forced; and his conservatism will soon give way to interest. We are assured that it is only

by attention to such factors as these (above enumerated) that mining has ever become a success in the East, while in the instances when they have been ignored or neglected, the outcome has invariably been loss and failure. —Raymond Russell.

NOTES ON TEA.

[By PERCY HWINNOR, Esq., late of Sylhet, Cachar, and Assam.]

Manufacture. Withering. The old method of withering was to spread the leaf 2 to 3 inches thick on a machan, and to turn it over several times during the night to prevent its heating too much. In wet and cold weather it was placed in small quantities at one time, on a machan, over the firing chooks, where the heat quickly softened and prepared it for rolling. But now great improvements have been made in the factory buildings and accommodation. It is generally recognized that the leaf must be thinly spread out, and the withering process most carefully conducted to turn out good tea. Withering sheds admitting air and light freely, and fitted with tier upon tier of bamboo trays, are made. Large pukka lion roofed tea houses are fitted with lots for withering, and arrangements are made for regulating the heat and admitting or shutting out the air.

Natural withering, as generally understood, means that the leaf is placed in open or closed houses in which the draught of air may be regulated, while artificial withering includes the use of heated air, or of machinery.

A large proportion of the best tea which is sent to the market is now made from artificially withered leaf, that is to say, from leaf which has been withered by heated air. The lots of the pukka tea houses are heated by the sun, to a temperature of over 100 degrees, and are often intolerably and suffocatingly warm. In dull and wet weather also, the temperature in these places is still considerably higher than that of the surrounding atmosphere as they are heated by stoves or other firing machines, the chimneys of which pass through them.

There has for a long time been a strong prejudice against artificial withering. Closed hot houses were used because the withering, under favourable circumstances, is always supposed to give the best results.

In natural withering, the faster the process the better the result, so we may conclude that perfect withering would consist in removing all superfluous water from the leaf instantaneously, without disturbing the oils, juices, &c., while sufficient heat was applied to reduce the fibre to the soft condition required for rolling.

A series of careful experiments have been made in a small house heated by smoke flues, with one mound of leaf spread on about 15 square feet to a pound. It was found still, that the faster the operation the better the result. That the greater the heat, the thinner the leaf must be spread, and the more care and dexterity required.

The finest tea was made from leaf withered in 3 hours, at a temperature of 140 degrees. The tea was of several occasions carefully assayed, and true samples of the bulk were sent down to Calcutta to be valued, and the quality of the liquor as well as the appearance were pronounced excellent. The average valuations were about 14 annas, and the leaf was good, but not finer than that plucked on most estates in Dairajoling, or Sylhet, or Cachar, being two leaves and a bud. The market at the time was depressed, and the average price of the teas of the districts named was, at that time, between 9 and 10 annas.

In 1883 the entire crop of the Kaloagar Estate, Sylhet, just under 900 mds, was withered in hot houses, heated by smoke flues, and realized 11 annas per lb. average. The houses were "kitchens" built of bamboo and plastered skur. They were 14 feet high in the roof, 7 feet high walls, breadth 2 1/2 feet. Two four feet wide, passages and 4 rows of chimneys 3 feet wide.

The pipes were 9 inches in diameter, and 1/2 inch thick, and ran along both sides of the house underneath the outer row of chimneys. The heat was much greater near the furnaces than at a distance from them, and the house gets thoroughly heated for a distance of about 15 to 20 feet only from the furnaces.

The heat is also uneven, and the greater it is the more difficult it becomes to equalize the withering. The leaf must be thinly spread and carefully watched. One part of the house wither much more quickly than another, and if the leaf is left for an hour only, after it has reached the right stage, much quality is lost.

These houses, defective as they are, are preferred to those of the old style.

When the men have learnt how to arrange the leaf, and work the fire, the rolling can be commenced at 5 A.M., every day, in all weathers.

The leaf does not turn red unless it be bruised in some way during the withering process, and its juices become exposed to the air. This may happen from the leaf being gathered up a second time, and removed from one place to another.

If it is once established beyond dispute that the best tea can be made from artificially withered leaf, there should be no difficulty in making a hot chamber in which the leaf could be very thinly spread out and the heat equalized and regulated, and the moisture removed.

One of the great disadvantages of open houses is, that the damp cold air which checks the withering is admitted, as well as the warm air which favours it. Withered leaf retains moisture, and is refreshed by it—as a bouquet of faded flowers is revived by sprinkled water. But when the leaf has withered a second time, it loses its freshness, and when the flowers have again faded, they begin to give out an offensive smell, the first stages of decomposition having set in in both cases. Leaf which has once lost its vitality freshness and delicacy, never recovers it, and can never be converted into fine tea.

The fine qualities in the leaf may be chemically altered in the hot withering process, but they are not lost altogether as is proved by the quality of the tea produced by it.

In the same way, however, as the flavour of the tea is affected by different firing processes, so it is probably also affected by the degree of the heat applied in the withering, as well as by the manner in which it is applied.

(Good tea can be made of leaf which is carefully withered, rolled, fermented, and finally baked out, although strong, it is peculiar, and has not the delicate flavour and smell of tea, which is roasted over charcoal in the usual way, and this again is not so aromatic in flavour as that which is dried by the rapid hot air draught of the "Strucko")

It would appear that the best withering would be accomplished by a strong draught of moderately warm and quite dry air passing over the whole surface of the leaf.

If the juices can be kept uninjured, the more the leaf is withered, the better the quality of the tea. The presence of water in the rolled leaf appears to affect the fermentation injuriously. It is not accurately known at present what chemical changes take place in the various systems of manufacture, but we know that the more or less dependent on the weather, and that the changes which take place satisfactorily one day, will not do so on another, under apparently exactly the same condition. Lightly withered leaf makes tea without strength or body, and this is probably due to the presence of too much water in the rolled leaf which causes an injurious fermentation. On the other hand, over withering, or bad withering, by which the juices have been injured or destroyed have the same effect and produce weak pale liquored tea.—*Planters' Gazette* (English Paper)

A SKILFUL SURGICAL OPERATION.

THE American Ambassador at Vienna, Mr. Kasson, has lately forwarded to his Government an interesting account of a remarkable surgical operation lately performed by Professor Billroth, of Vienna, which, wonderful to tell, consisted in the removal of a portion of the human stomach, involving nearly one third of the organ and, strange to say, the patient recovered—the only successful operation of the kind ever performed. The disease for which this operation was performed was cancer of the stomach, attended with the following symptoms—The appetite is quite poor. There is a peculiar indescribable distress in the stomach, a feeling that has been described as a faint "all gone sensation," a sticky slime collects about the teeth, especially in the morning, accompanied by an unpleasant taste. Food fails to satisfy this peculiar faint sensation; but, on the contrary, it appears to aggravate the feeling. The eyes are sunken, tinged with yellow, the hands and feet become cold and sticky—a cold perspiration. The sufferer feels tired all the time, and sleep does not seem to give rest. After a time the patient becomes nervous and irritable, gloomy, his mind filled with evil forebodings. When rising suddenly from a recumbent position there is a dizziness, a whistling sensation, and he is obliged to grasp something firm to keep from falling. The bowels constive, the skin dry and hot at times, the blood becoming thick and stagnant, and does not circulate properly. After a time the patient spits up food soon after eating, sometimes in a sour and fermented condition, sometimes sweetish to the taste. Often times there is a palpitation of the heart, and the patient fears he may have heart disease. Towards the last the patient is unable to retain any food whatever, and the opening in the intestines becomes closed, or nearly so. Although this disease is indeed alarming, sufferers with the above named symptoms should not feel nervous, for one hundred and ninety nine cases out of a thousand have no cancer, but simply dyspepsia, a disease easily removed if treated in a proper manner. The safest and best remedy for the disease is Seigel's Curative Syrup, a vegetable preparation sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White (Limited), 17, Farringdon Road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

Dr. MARK TALLEY, F.R.S.E.D.

November 29th, 1891

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years with dyspepsia; but after a few doses of the Syrup, I found relief and after taking two bottles of it I feel quite cured.

I am, Sir, yours truly,

Mr. A. J. WHITE.

WILLIAM BRENE.

September 8th, 1883.

Dear Sir,—I find the sale of Seigel's Syrup steadily increasing. All who have tried it speak very highly of its medicinal virtues, one customer described it as a "Godsend to dyspeptic people." I always recommend it with confidence.—I faithfully yours,

(Sd.) VINCENT A. WILLS,

To Mr. A. J. WHITE. Chemist Dentist, Murthyr Lydval.

Seigel's Operating Pills are the best family physic that has ever been discovered. They cleanse the bowels from all irritating substances, and leave them in a healthy condition. They cure constiveness.

Preston, Sept. 21st, 1883

My dear Sir,—Your Syrup and Pills are still very popular with my customers, many saying they are the best family medicine possible.

The other day a customer came for two bottles of Syrup and said "Mother Seigel" had saved the life of his wife, and he added, "one of these bottles I am sending fifteen miles away to a friend who is very ill. I have much faith in it."

The sale keeps up wonderfully, in fact, one would fancy almost that the people were beginning to breakfast, dine, and sup on Mother Seigel's Syrup, the demand is so constant and the satisfaction so great.

I am, dear Sir, yours faithfully,

(Signed) W. BOWEN.

To A. J. WHITE, Esq.

Spanish Town, Jamaica, West Indies, October 24, 1882.

Dear Sir,—I write to inform you that I have derived great benefit from "Seigel's Syrup." For some years I have suffered from liver complaint, with its many and varied concomitant evils, so that my life was a perpetual misery. Twelve months ago I was induced to try Seigel's Syrup, and although rather sceptical, having tried so many reputed infallible remedies, I determined to give it at least a fair trial. In two or three days I felt considerably better, and now at the end of twelve months (during continued taking it), I am glad to say that I am a different being altogether. It is said of certain pills that they "come as a boon and a blessing to men," and I have no reason to doubt the truthfulness of the statement. I can truly say, however, that Seigel's Syrup has come as a "boon and a blessing" to me. I have recommended it to several fellow sufferers from this distressing complaint, and their testimony is quite in accordance with my own. Gratitude for the benefit I have derived from the excellent preparation, prompts me to furnish you with this unsolicited testimonial.

I am, dear Sir,

Yours ever gratefully,

(Signed) CARRY B. BERRY,

Baptist Missionary.

A. J. WHITE, Esq.

Hensingham, Whitehaven, October 16, 1882.

Mr. A. J. WHITE.—Dear Sir,—I was for some time afflicted with piles, and was advised to give Mother Seigel's Syrup a trial, which I did. I am now happy to state that it has restored me to complete health.—I remain, yours respectfully,

()

THE TROPICAL AGRICULTURIST:

A MONTHLY RECORD OF INFORMATION FOR PLANTERS OF

Rubber, Cacao, Cinchona, Coffee, India rubber, Sugar, Palms, Cotton, Cardamom, Kola, Cloves, Cinnamon, Nutmegs, Fibrous Plants, and other Products, suited to Cultivation in the Tropics.

[Published at the Office, Colombo, Ceylon, on or about the 1st of each Month. Commenced in June 1891.]

"THE TROPICAL AGRICULTURIST" has now an assured position in its large circulation in Ceylon, Southern and even Central and Northern India, the Straits Settlements, Sumatra, Java, Borneo, Northern Australia, Queensland, Central America, Natal, Mauritius, and the West Indies. From all sub-tropical planting settlements, we have had cordial approval of the publication, and an encouraging measure of support. The English, Indian, and Colonial Press have spoken in commendatory terms of the T. A., as also directors of Public Gardens, from Sir Joseph Hooker, F.R.S., downwards, and all planter.

No planter should be without it.

Rules of Subscription, including postage, in advance.

12 Sterling — Rupees 12 — 5 Dollars.

Single copies, 3s or Rs. 1, bank copies, 3s or Rs. 1 1/2.

Any one of the four volumes completed, bound in cloth, lettered, with comprehensive index, for 12 10s (or Rs. 12), carriage prepaid. As a medium for English, American, and Australian ADVERTISERS, the TROPICAL AGRICULTURIST is of great value for the tropics, India, as well as Ceylon, the Straits Settlements, Java, and West Indies (Central America being included in that term), or connected with agriculture, the Tropical Agriculturist stands unrivalled, the work being constantly in the hands of Native as well as European and American agriculturists. Being a monthly periodical, the Tropical Agriculturist lies on the table, and is very often referred to during each month, a fact which advertisers will know how to appreciate.

For the sale of plants, seeds, machinery, implements, &c., used in tropical (tea, sugar, fibres, &c.) agriculture, no better advertising medium exists.

Rules for Advertisements.

HOLLOWAY'S PILLS can be confidently recommended as a domestic remedy for the ailments of all classes and conditions of people. Young and old of both sexes may take this medicine with the certainty of deriving benefit from its use, when afflicted by disease is making them miserable. Holloway's Pills are recommended for their purifying, aperient, and strengthening properties. They remove indigestion, palpitation, and headache, and are generally serviceable in complaints peculiar to females. Each box is wrapped with printed instructions for the guidance of the patient, who will readily understand, from carefully studying them, the best way of recovering health. Holloway's Pills will work a thorough change in the constitutions of the weak and nervous.

INDIAN AGRICULTURIST.

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA.—SATURDAY, OCTOBER 10, 1885.

[No. 41.]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING 30TH SEPTEMBER 1885]

Madras.—General prospects fair. Much improved in Bellary and Anantapur. Small-pox, fever, and cattle-disease are reported as generally prevalent in all districts.

Bombay.—Good rain in all the districts of the Deccan and Southern Mahratta country. More rain urgently required throughout Gujarat, where crops are withering and in parts of Khandesh, sowing of rabi crops commenced in most districts of the Deccan and in parts of Bijapur and Belgaum. Fodder scarce in the eastern talukas of Belgaum and Dharwar. Standing crops damaged by rats, worms, and storms in parts of Hyderabad, and by drought in parts of Kurnool. Cholera in parts of sixteen, and fever and cattle disease in parts of ten districts.

Bengal.—Rain in all districts during the week. Prospects of crops are good, except in the flooded tracts in the Burdwan and Presidency divisions, and in Behar, and also on the sea coast of Orissa, where cyclone of the 22nd instant caused great damage. Bhadoi crops, where not injured by floods, are being harvested with fair results. Price of rice continues high all over the province. Fever is prevalent in some districts, but public health, on the whole, is fair.

N.-W. Provinces and Oudh.—Rain has fallen generally throughout the provinces, but more is needed in some places. *Aharis* have benefited from the rain, and harvesting operations have begun in a few districts. Prices are steady, and prospects on the whole good. Cases of cholera and fever continue to be reported, otherwise public health is fair.

Punjab.—No rain. Fever in the Hissar, Delhi, and Peshawar districts, and in the Kahuta tehsil of the Rawal Pindia district elsewhere the health is generally good. Rabi operations in progress in the south-east. Prices on the whole steady.

Central Provinces.—Prospects much improved by recent rain, but more is still required, especially in Nimar, where fall is much below average. Prices steady.

British Burmah.—Cholera slight in four districts elsewhere public health good. Cattle disease severe in one district, slight in three districts, elsewhere health of cattle good. Crop prospects good.

Assam.—Weather fair. Fever prevalent, cattle disease still reported from some mouths. Ploughing operations commenced for sowing *mat* and mustard. Prospects of all crops good.

Mysore and Coorg.—Much rain needed everywhere. Standing crops withering in Mysore district and backward in parts of Kolar district, but in Tumkur district they are reported to be reviving in localities where rain fell. Cattle in poor condition. Water supply sufficient for the moment. Prospects of the season reported good in Mainad taluka of Kolar and Shimoga districts, and less gloomy in Mardani taluka. Improving in Bangalore and Tanjore districts. Fodder scanty. Public health generally good, except in parts of Tumkur, Kolar, and Shimoga districts, where fever prevails. Prices slightly rising, except in Shimoga and Kolar. The recent rise in Shimoga reported last week due to exportation to Bellary. Speaking generally, the rain has done good, and the outlook is a little less discouraging than it was last week.

Bihar and Hyderabad.—In the Akola and Julgaon talukas prospects have improved, but more rain is required. Crops on other talukas in good condition. Rain has been beneficial to standing crops. General health fair. Prices—wheat 12½, coarse rice 12½, white rice 17, yellow rice 21, and for 1½ annas per current mode rupee.

Central India State.—Weather clear, with cool nights. Prospects of crops improving. Prices stationary. Health good.

Gujarat.—Crops prospects fair. More rain wanted. Two cases of cholera in the city amongst pilgrims, fever at Rajangab, otherwise health generally good. Prices stationary. Weather clear.

Hyderabad.—Prospects good.

Letters to the Editor.

ORANGE CULTIVATION.

TO THE EDITOR.

SIR,—Having read your correspondent "T's" letter, and your note on this subject, in a recent issue of your paper, it has occurred to me that you have under-estimated the average price of oranges in the Calcutta market. It is true that you can get oranges at four annas the score, but that is an exceptionally low rate, and applies to fruit of inferior quality, for it is seldom that you can get good fruit at that rate. I have myself bought them six to twelve annas the score. When selling the produce of the trees in my garden, I have invariably realised eight annas per score. Of course, it must be remembered that the fruits from my trees were of superior quality. The variety I cultivate is the 'Sythet,' but I have also the "Ombra" of the Punjab, which, though it yields splendid fruit, is not such a heavy cropper down here. In the Delhi district it grows to perfection, and the fruit attains a very large size. I have seen trees literally covered with fruit, so much so, that branches have given away with their load of fruit, a large portion of which had to be removed before ripening, to save the trees from perishing through exhaustion, and being torn down with a superabundance of fruit. The plan you recommend for cultivation is the one I myself have adopted for many years. There is nothing like well-decomposed night-soil, cow-dung, and common black "bank" soil, with an admixture of slaked lime, or old mortar freely powdered, for growing the orange in. In fact, orange trees planted entirely in old mortar have been known to yield excellent crops.

It may not be out of place to mention that the very best method of raising orange trees, is by budding. It is the quickest, surest, and most economical. By seeds, you are apt to get plants yielding indifferent fruit, as I have found from experience. You may, perhaps, get 10 per cent good plants, but then you have to wait for many years to make your selection. Whereas, by budding, you are certain of your variety, and the plants thus raised, invariably fruit the third year. I have found the common lemon or *khatta*, as it is called in Upper India, the best to use for stocks to bud upon. These are raised from seeds, and are ready for budding upon in February. The sweet lime, or *moos moos*, is said to make a good stock also; and it is alleged that the fruit of trees budded on these are sweeter than those on the *khatta* (literal, sour). I have, however, not been able to detect the difference. I have seven *beeghs* devoted to orange cultivation for the market, and I get an average yield of Rs. 200 per *beegh*. My trees are planted ten feet apart, but I think they are too close. As 8½ Bengal *beeghs* are equal to 1 acre, my average revenue will be equal to Rs. 700 per acre. My annual expenses do not exceed Rs. 200, so that I have a clear profit of Rs. 500 per acre.

Another point which I think worth mentioning is, that I change my stock of fruit-bearing trees after three years of full bearing. After 12 years' experience in the cultivation of the orange, I have found that when trees bear their full crop for three successive years, they begin to die off most unaccountably. I can assign no scientific reason for this; but I have come to the conclusion that, by having a stock ready in the nursery, and planting out between the old trees from the time they first begin to fruit, there is always a fresh lot of trees ready to replace the old ones from the year they begin to show signs of dying off. Thus, you avoid the risk of losing your revenue even for a single year. The expenditure is trifling, and the gain much. If your correspondent "T" intends going in for orange cultivation on a remunerative scale, he should bear this last fact in mind. For, although I have seen orange trees live to

a good age, I have not known them to fruit satisfactorily. In the Hoogsoon district, Delhi division, are to be seen miles of orange plantations; and I candidly confess that, nowhere in India have I seen this delicious fruit grown to greater perfection, although apparently little or no care is devoted to its cultivation. The fruit is there sold by the *maund*, and I have myself bought them at Rs 4 to Rs 6 the *maund*. In these plantations I have seen very old trees; but they had a gaunt and "needy" look about them, and the *malles* assured me that they were always replacing these old trees by young ones raised by budding. To grow the orange to perfection in Bengal, the danger to be guarded against is too much tenacity in the soil round the roots. The soil in Bengal is a heavy black, clayey loam, and this must be rendered friable by lime, sand, and cowdung well decayed. A little leaf mould occasionally would not be amiss. There is no fruit that will yield so well, with so little care and attention as the orange; and there is scarcely a fruit I know that is more wholesome. It should be widely cultivated; and if I can help you to foster a taste for orange cultivation, I shall be most happy to give any information that lies in my power.

AN OLD "MALLEE"

October 2, 1885.

II.

TO THE EDITOR.

SIR,—I am much obliged for your note on orange cultivation. Would you be so kind as to let me know why the orange should be budded on to the common lime or lemon, rather than raised from seed or seedlings of orange trees? Young orange seedlings are procurable in this district. Would it be best to use these seedlings or by budding?

Would you be so good as to quote some book where I can find instructions about budding, which would seem to entail some special knowledge and practice?

Your figures are not quite clear to me. You say 5 to 8 acres would be sufficient land to plant up to promise a return of Rs. 5,000 per annum. But 100 trees to the acre (i.e., trees planted 20 x 20), yielding 350 oranges per tree, would produce 1,750 score. Selling these at 4 annas per score = Rs. 400 per acre gross return, setting away half for loss, bad seasons, superintendence, upkeep and expenses, we have a nett return of Rs. 200 per acre. Consequently we should plant up 30 acres for a return of Rs. 6,000, and it would be more prudent to take up 50 acres, and plant out 5,000 trees.

T.

NOTE.—We publish to-day a letter from a correspondent, who has had much experience in orange cultivation, which furnishes nearly all the information our correspondent "T" wants, especially as an answer to the first question. As to the second query, we should recommend him to procure the seedlings now, and use them for budding good varieties upon in February next. Fleming's "Manual of Gardening for India" (3rd edition) is the best book we know of. We fear we were a little out of our calculations; the information was furnished to us by a correspondent. But having enquired personally into the rates obtaining in the Calcutta market, we are told that three qualities of fruit are sold. The best fetches from 10 to 12 annas, the next from 8 to 9 annas, and the last from 5 to 6 annas per score. This would give an average of nearly 8 annas per score. Therefore one acre of land planted with 100 trees yielding 1,750 score, at 8 annas per score, would realize Rs. 875 per acre, or Rs. 7,000 from 8 acres. Allowing Rs. 1,000 a year for expenses would just leave the 6,000 clear profit. However, to be on the safe side, 10 or even 12 acres might be planted. The expense would only be in the first outlay, for we do not suppose our correspondent meditates employing an expensive staff for supervision, one *malles* or Rs. 1 per man-*em* and two coolies on the 5 per *mansam* would be quite sufficient for all practical purposes.—ED., I. A.

MANGO PESTS, &c

TO THE EDITOR.

SIR,—(1) Your correspondent, Mr. Hari Chander Dutta, has been conferring a great boon on the public by contributing numerous articles on the propagation of mango and other trees. I shall be obliged if he or any other gentleman will be good enough to say what the remedy is for the extermination of small white round worms, which find access to the roots of young mango plants, and so thickly cover them up that there is a separation between the roots and the earth, with the result that the young plant dies away in course of time. These larvae are not found above the surface of the ground; but there are to be seen small ants of an ash color over the ground and crawling on the stems of the plant. The surface of the ground about a quarter of an inch around the stem is a little loosened, and this fact, as well as the appearance of the ants moving about the stem, are signs of the existence of the small white worms under the ground. I have tried various remedies to eradicate or kill the worms without injuring the plants,

but my attempts have all proved failures. In this way I have lost a large number of grafted mango plants purchased at high prices from the people who bring them to from Vinsagpetam.

It is remarkable that the worms I allude to do not injure, or appear in any other kind of plants in the vicinity.

(2) I should also like to know what the best treatment is for the growth of mango trees. In this town, which is some four miles from the sea (71 feet above the mean level), large mango trees even do not thrive well. The high winds blowing between March and September injure the tender leaves, and the branches wither away, commencing from the extremities until the whole tree dies. In most cases, the leaves are not healthy, being perforated a few days after budding by worms, which are not visible. In some instances the decay of a tree thus injured is attributed to larvae boring the wood. Can a remedy be suggested for the above also?

(3) Lastly, I planted, six years ago, orange trees in my garden. They are now tall, being 12 feet in height, without the corresponding bulk, but do not bear nor flower. Your valuable opinion is solicited about the improvement of this tree also.

A. GURUMURTY,

Head Clerk, Collector's Office,
Mangalore District.

Chattrapote, September, 30, 1885.

NOTE.—(1.) The following emulsion has been found an excellent insecticide.—Take one quart of soft soap to one gallon of boiling water. Add one gallon of kerosine oil to every two gallons of soap solution, and make an emulsion by violent stirring of the mixture. Syringe the trees with this, or apply with a painter's brush over the branches.

(2) We should recommend wood ashes, bone dust or a liquid manure, composed of fresh horse-litter and wood ashes. These have been found excellent fertilizers.

(3.) Perhaps the orange trees have been raised from seed. If so, there is very little chance of their fruiting for the next 2 or 3 years. A judicious root and head pruning in January, with an application of a compost, consisting of well-decayed night soil, cowdung, common black tank soil, and slaked lime (equal quantities of the first three, and a fourth part of the last named) might have a good effect. We should ourselves certainly try the remedy.—ED., I. A.

Editorial Notes.

We are glad to learn that Mr. M. Finucane, C.S., Director of Agriculture, Bengal, has proceeded on a tour to inspect the state of agriculture in several districts in the mofussil.

The net amount of Indian sea and land customs revenue, exclusive of the salt revenue, for the first five months of the current official year, amounted to Rs. 45,20,000, against Rs. 37,37,000 during the corresponding period of last year.

We have received a mass of correspondence from the Revenue and Agricultural Department of the Government of India, regarding the effects of soil and cultivation on the color of wheat. The subject is an important one, and we hope to review it in detail next week.

A RANGOON paper says that the quantity of currant-apples imported into Rangoon from Prume is almost incredible, though strangely enough the consignees of the fruit are only three Burmese women. It is evident that the fruit finds ready sale, from the fact that the importations are daily all cleared by 10 A.M. from the railway goods shed.

The quantity of tea exported from China and Japan to Great Britain, from the commencement of the season to the 11th September, was 102,448,669 lbs., as compared with 91,112,906 lbs. exported in the corresponding period of last year. The exports to the United States and Canada during the same period amounted to 29,414,271 lbs., as against 41,573,361 lbs.

If what the *Farmers' Review* says about the sunflower is true—and we have no reason to doubt the statement—it is really a very useful plant; and instead of being regarded as a weed, as it has hitherto been in India, it ought to take a prominent place among the cattle-feeding crops of the country. We recommend a parcel of the extract which we have found among our selections.

Dr. E. B. DUNN, of Hawaii, has long been known as a prolific writer on agricultural subjects in India. He has contributed some able papers to our columns, and from time to time he has addressed practical letters to the *Pioneer*, the latest of which contains an account of a particularly fine variety of the lettuce, with hints upon how it may be grown to the best advantage. The letter itself will be found among our selections.

It appears that the supply of salt from the Sambhur Lake was very seriously interfered with last year by floods in the hill streams, which poured such large quantities of fresh water into the lake that manufacture was stopped. The total output for the year 1884-85 was only 378,093 maunds, as compared with 8,614,671 maunds in 1882, and 4,343,697 in 1883. In consequence of the failure of supply, the minimum selling price of Sambhur salt, which had been reduced from 4½ to 3½ annas per maund, was raised to 9 annas at the end of June, 1884, which led to large quantities of salt being imported from Baragana, in the Bombay Presidency, from Calcutta, and from the Punjab mines.

We understand that a Wisconsin farmer who has given on a five-years' test, gives the conclusion he has reached, thus: "To get the best result is to have your corn just ripe, cut and haul when dry and no dew on it, run it through the cutter and cut it fine, and give it time to heat a little as you cut, so it will pack better as the pressure increases; and it will also keep a great deal better when open for use. I have used one inch boards for covering laid double, so that no cracks came opposite, and about 600 pounds of stone for pressure to the square yard of surface, and I will say to any man that likes to have good feed for his stock that corn put into a good silo, the way I have described, will come out nice and sweet and good enough to feed to the highest-priced Short-horn, the noble Hereford, the comely black and white or the fine-bred Jerseys."

A CONTEMPORARY observes that the cultivation of potatoes on the Neilgherries has long been a source of profitable enterprise, and as the natives are gradually learning to appreciate the tuber, it is satisfactory to learn that there are hundreds of square miles of arable land, which the hill tribes cannot profitably cultivate with their ordinary grains, but which, put under this vegetable, as the demand increases, would maintain their owners in comfort. The best elevation for the cultivation of the potato is above 6,000 feet, though experiments in the extreme north and south of the hills at 3,000 and 4,000 feet have not been quite failures. The extent of land under cultivation is estimated at 1,000 acres, including large areas of semi-drained swamps within the town of Ootacamund. Two crops are raised annually—one sown in February and lifted in July, the other sown in August and lifted in December.

There seem to be doing a good business in the production and sale of petroleum in the Caucasus. The *Génie Civil* tells us that there are about 400 wells in the vicinity of Baku, but only about half of them are at present being worked. The gross total of the petroleum extracted during the last three years is as follows:—800,000 tons in 1882, 1,000,000 tons in 1883, and 1,200,000 tons last year. Nearly the whole of this is converted into lamp oil at Baku itself, about a pound of good oil being obtained for three pounds of petroleum. There are 150 petroleum refineries at Tchorny Gorod (the Black Town) and Baku. In the course of last year, 200,000 tons of lamp oil, 100,000 tons of second-quality oil, and 500 tons of residuum were exported; these figures showing a slight increase over those for 1883 and 1882. The exports were distributed in about the same proportions over the principal countries of Western Europe.

General Sir James Fergusson, writing recently to the *British Trade Journal* on the pearl trade of the Persian Gulf, says:—

"The pearl trade of the Gulf has been famous from the earliest historic period; and the great wealth of the islands of Bahrain,

and of the small maritime chiefdoms known as, Dohal, Shingeb, Amulgwaine, and Rasulkhyma, on the Arab shore-lies of the Gulf, are still the richest pearl-fishing grounds in the world; and yet, perhaps, the finest pearls still swirl about on the sands at the bottom of the Gulf waters. The law seems to be that the deeper the water the finer the pearl or the oyster, and the deeper water along the banks has never yet been fished. The Arabs pursue their fishery by diving from small craft, which during the pearl season may be seen anchored by thousands along the banks. Seven fathoms is the maximum depth of their diving, while their ordinary fisheries are pursued in from four to five fathoms of water. Now, as the water deepens very slowly off the Arab coast, and as this shoal water over the banks extends some hundreds of miles—from the reefs of Bahrain and Et Khairiff to Cape Muscat—it seems probable that, were the deeper water along these banks to be exploited by steamers fitted with regular diving apparatus, miraculous draughts of pearls might still be obtained.

One of the most curious and useful results of the application of science to manufacturing processes, was discussed at a recent meeting of the Iron and Steel Institute at Glasgow, when Mr. Jones, of the Langloan Iron Works, read a paper on the present position and prospects of processes for the recovery of tar and ammonia from blast furnaces. If anything would seem to be more hopeless than another, it would be the effort to recover any valuable products from the gases produced by one blast furnace, yet at the Carlisle Iron Works, the tar and ammonia are being recovered from the gases of eight furnaces, and thirty tons of sulphate of ammonia are thus recovered every week. This prevention of waste, or recovery of valuable products that we have hitherto thrown away, is one of the most valuable services that modern science can perform in cheapening production. It is unfortunate that hitherto, no satisfactory means have been found of fixing and saving the valuable part of the sowing of great towns, but the escaping gases of a blast furnace would seem to be less likely to yield useful products than the water of a drain.

The following circular order issued by the Board of Revenue, on the subject of *tuccasi* advances to the cultivator, will be read with a good deal of pleasure, by every one who is interested in the relief of the people:—

The Board have been desired by Government to point out that the Agriculturists Loans Act, No. XII of 1884, is not intended to supersede altogether the ordinary machinery of loans from mahajans, under which agricultural operations are carried on in this country. Its object is to enable the Government to step in, and assist the more needy cultivators with loans on those occasions of unusual pressure, when the local mahajans are unwilling to run extraordinary risks. In granting loans, therefore, under the Act, some discretion should be exercised by district officers; preference should be given to cultivators of the poorer classes, and an attempt should be made to distinguish these from persons whose credit is good enough to enable them to obtain loans on reasonable terms from the local money-lenders.

This is precisely the order that was wanted, and if our district officers will but loyally carry it out, immense relief will be given to the people without any very serious loss according to the State.

We learn that Sir J. B. Lawes has concluded his report on the ensilage experiments at Rothamsted. "Upon the whole," he writes, "the analytical results clearly show that the milk of the mangel-fed cows throughout contained higher amounts of both total solids and butter fat than that of the silage-fed cows. Yet, quite consistently with the observation of others on the same points, the milk of our silage-fed cows was judged, both by colour and by taste, to be richer than that of the mangel-fed cows. The milk of the silage-fed cows possessed a slight, but not at all disagreeable, flavour, which may be described as hayey, and which could readily be detected by some, but not by others. The butter from the milk of the silage-fed cows was also much yellower than that from the milk of the mangel-fed cows, but there was no perceptible difference between the two as to taste." On this subject, an interesting letter will be found among our selections from the pen of Mr. Thos. Esdaile, of Northallerton.

The following summary of the Board of Trade returns for August 1885 is taken from one of our English exchanges :—

The Board of Trade returns for August and eight months ended 31st August have just been issued, and in common with those of the majority of the preceding months of the year show a decrease in all branches of trade. The value of goods imported during the month amounted to £28,956,976, against £29,610,739 in 1884, and £36,224,888 in 1883, being 2·2 per cent less than in 1884, and 20·6 per cent less than in 1883. For the eight months the total is £253,297,443, against £262,753,496 in 1884, and £287,103,694 in 1883, a decrease of 3·6 per cent. and 11·8 per cent respectively. With regard to the import trade of the month as compared with that of August 1884, animals, living (for food), have declined from £1,179,090 to £991,213 or 16·0 per cent, principally in oxen from Denmark and the United States, and sheep from Denmark, Germany, and Canada. The imports of wheat have declined from 5,706,594 cwt. to 5,232,150 cwt.; of wheat flour from 1,147,134 cwt. to 775,841 cwt.; and of oats from 1,460,385 cwt. to 1,204,687 cwt.; but those of barley have increased from 531,136 cwt. to 716,675 cwt.; of beans from 303,642 cwt. to 315,506 cwt.; and of Indian corn from 2,035,243 cwt. to 2,201,014 cwt.—the total value of corn and meal amounting to £3,752,185, against £4,585,537, a decrease of 18·2 per cent. Cheese is less by 69,775 cwt. and £258,167; lard by 20,175 cwt. and £56,002; rice by 101,024 cwt. and £80,167; and sugar, refined and unrefined, by 110,655 cwt. and £74,688.

We have had an opportunity of looking through the *Tea Planter's Vade Mecum*. It is a handy volume, compiled by the Editor of the *Indian Tea Gazette*. The nature and scope of the book are best explained by a brief reference to the very full synopsis of contents. The work is divided into sections, of which there are 27, under each of which is classified all matter relating to the special subject treated of. Thus, cultivation, manuring, blight, manufacture, &c., are treated of in separate "chapters," or "sections," in which is contained everything known, apparently, on each subject. There is an advantage in this form of arrangement, as it permits of ready reference to a particular matter, where all the information regarding it is to be found. In this sense, the book may be termed almost a dictionary, or encyclopædia of tea and tea matters. As a book of general instruction and reference, it should find a place on every tea-planter's bookshelf. The work also contains some very able specialist professional articles on timber for tea boxes, and on the use and care of steam engines in tea factories, which should prove of great value to tea estate managers; while the chapter devoted to a description and review of the different kinds of tea machinery in use, ought to be of much use, as enabling the relative merits of inventions to be compared. The author has had exceptional opportunities of collating all the information extant upon the subject of tea, which must have cost him infinite labour and trouble to put together in its present shape. We regard the *Vade Mecum* as an authority on tea.

The Indian Salt revenue for the first five months of the current financial year shows a steady increase. It amounted during this period to Rs. 2,50,73,000, against Rs. 2,42,87,000 for the corresponding period of 1884-85; Rs. 2,36,75,000 for 1883-84; Rs. 2,25,57,000 for 1882-83; and Rs. 2,81,61,000 for 1881-82, the year during which the higher tax was in force. The loss on the five months' operations, as compared with 1881-82, which in the first year of the reduction amounted to over Rs. 56,00,000, has this year been reduced to Rs. 30,88,000. The quantity of salt on which duty was paid in the five months of this year was 12,845,000 maunds, against 11,195,000 maunds in 1881-82, showing an increase in consumption of 1,650,000 maunds. The rate of increase has been as follows :—1882-83 over 1881-82 (first five months), 431,000 maunds; 1883-84 over 1882-83, 638,000 maunds; 1884-85 over 1883-84, 350,000 maunds; and 1885-86 over 1884-85, 243,000. It is therefore evident that some years must still elapse before the salt revenue at the reduced tax will reach the figure at which it stood before the reduction. All the provinces share in the increase this year, as compared with last year, except Bengal and British Burmah. Bengal shows a falling-off during this period of Rs. 7,30,000, and British Burmah Rs. 36,000. The

Bombay Presidency shows the largest increase, viz. Rs. 10,92,000, and Northern India comes next with Rs. 4,10,000, Madras Rs. 49,000, and Sind Rs. 20,000.

The *Civil and Military Gazette* notices the annual report of the Agri-Horticultural Gardens, Lahore, in the following terms :—

Under Mr. Hein, the new superintendent, "the gardens have greatly improved in every way, and many changes for the better have been taken in hand." A plot of land to the south of the cricket ground which, as the report says, presented "an unsightly appearance," has been levelled, and during the past nine months planted with orange trees. Elsewhere, overcrowded vegetation has been cut away; English rose cuttings have been planted out by the hundred; and the appearance of the gardens in spring is ample proof of the incessant care devoted to them. But it is to more practical matter that the report mainly refers. A number of experiments have been tried with plants and seeds. Most of the attempts at acclimatization failed. In May of the year 1884, twenty varieties of sugar-papaw were received from Singapore. The case had been two months in transit; and, eventually, all the outtings died. Seeds of the *cryptomeria japonica* from Bangalore failed to germinate; and some Italian turnip seeds germinated so luxuriantly, that the plants forgot to grow turnips below ground, and was discarded. With mahogany seed the Superintendent had better luck. Nearly one hundred young and healthy plants have been reared. Experiments were also made in Khaki, Nankin, and Georgia Sea Island cotton. The second variety, though sown in poor soil, produced well. From one seer of seed were obtained 4½ seers of clean selected cotton, and fifteen seers of good seed. Some one, attracted by the beauty and gloss of the staple, stole a quantity of the Georgia Sea Island cotton, and sadly diminished the out-turn of the crop.

We have not seen the report, but our contemporary

Ensilage experiments were, without exception, failures. One pit, filled with Indian corn, smelt so fearfully on being opened, that a "gentleman whose house was situated two hundred yards off complained about it." The contents of another pit, filled with turnip tops, *bhoora* and Indian corn mixed, were unanimously rejected by the garden bullocks. The test in this case was not a fair one; as the bullocks are well fed beasts, and as disinclined to eat "strange meats," as is the English servant maid to feed on "them Australian tinned things." Yet a third silo, covered for six months, returned nothing but a "mouldy mass, quite unfit for fodder."

This is very extraordinary; but as we have no details before us, it is difficult to arrive at a correct estimate as to the cause of these failures. If the most ordinary and elementary conditions of a silo had been observed, it is scarcely likely that these results would have followed. We fancy that those who carried out these experiments must have dug pits in the ground, and filled them up in the same manner as gardeners fill up pits with leaves and refuse for leaf-mould manure. For had the silos been properly constructed, and the fodder sufficiently weighted and made air and water tight, the "gentleman whose house was situated 200 yards off" would not have had occasion to "complain" of the silo.

In contrast to the ensilage experiment conducted at the Lahore Agri-Horticultural Society's Gardens, we read the following account of a similar experiment at the Nagpore Farm :— "The silo was merely a rectangular pit, 16 feet long, 10 feet broad, and 6 feet deep, plastered inside with cowdung. The *jowari*, which was very much stunted, was cut green and put into the silo on the 10th and 11th of November, the whole quantity weighing 66 maunds. The stalks were not cut up, and each cartload was well rammed down before the next was put in. The supply only filled the pit to a depth of 2½ feet, when it was covered with bamboo matting, dry grass, and earth to a total depth of five feet. The weight of the earth amounted to about 260 lbs. per square foot. The silo was opened after five months, and the whole of its contents, except a small portion round the edge of the pit, which had been damaged by mildew, was found in excellent condition. The weight per cubic foot of the ensilage when cut out was 15½ lbs., and as the report had

developed a sweetness which it does not generally possess, it was eagerly eaten by both horses and cattle." This farm is at present under the superintendence of a graduate of the Madras Agricultural College.

A correspondent notices that the cultivation of coffee in the Madras presidency is steadily extending. In 1874 there were 17,337 plantations, exclusive of 42 in the State of Travancore. More than half the total number of plantations are in Malabar, while in Madras there are 3,458, and in the Nilgiris 501. The elevation of the plantations varies from 800 to 6,000 feet. The total area taken up for the coffee cultivation in the presidency is 110,328 acres, of which 56,247 acres are under mature plants, 8,822 acres under immature plants, while 45,259 acres are only taken up for planting, but are not yet planted out. The total yield of coffee last year was 12,241,545 lbs. The average yield per acre ranged from 347 lbs. in Madras to 21 lbs. in Vizagapatam. The cost of cultivation per acre was highest in the Nilgiris, where it varied from Rs. 63 to Rs. 156, and lowest in South Canara, where it was Rs. 20-1-0. The Madras tea industry is also doing well. There are 84 plantations, all in the Vizagapatam, Madras, Nilgiris, and Malabar districts. These have a total area of 7,553 acres; of which little more than half is actually under cultivation. Last year the outturn reached 398,045 lbs. In Travancore there are 27 plantations, occupying a cultivated area of 1,497 acres. The total outturn was 108,740 lbs., of which the whole was black tea. As regards the coffee industry, it is surprising to find that Madras is making any progress at all, seeing that Ceylon has lost so much ground, but if the trade were recovering something of its old position there would be a golden future for large tracts of country in the presidency which are splendidly adapted for its cultivation.

The advices from Mysore are far from re-assuring, the province being we fear within measurable distance of famine, owing to the failure of the rains. It is but seven years since one-fourth of the population were swept away by the famine of 1877-78. The young Maharaja deserves every encouragement and assistance that the Supreme Government can give him, for in handing the territory back to native rule, we gave it back absolutely ruined, and with a debt of £800,000 upon its shoulders. As to exacting the enhanced tribute demanded of the Prince, it is out of the question altogether. The amount ought never to have been increased, when the result of our own direct administration of the province had proved to be so ruinous to its people. In some respects, the cultivators of Mysore appear to be more advanced than those of any other part of India, and they will not succumb readily to this new misfortune.

The following is a summary of the health, crops, and weather reports for the week ending 30th September 1885:—Rain has fallen in all districts of the Madras presidency from which reports are received. Prospects are generally fair, and have greatly improved in Bellary and Anantapore. More or less rain has fallen throughout the Mysore State, and prospects are less discouraging. More rain is wanted generally, especially in the Mysore and Kolar districts. In Coorg prospects continue favourable, but more rain is required in parts for the rice crop. Good rain is reported from all districts of the Deccan and Southern Mahratta country. In Guzerat and in parts of Khandesh more rain is urgently required. Rabi sowings have commenced in most districts in the Deccan and in parts of Bijapur and Belgaum. Fodder is scarce in parts of Belgaum and Dharwar. In the Berars the crops are progressing favourably, but more rain is wanted in Akola. In the Nizam's Territory the rainfall of the week under report has been beneficial to the crops, and prospects are favourable. More rain is much wanted in most States in the Central India and Rajpootana Agencies.

The recent rain has much improved prospects in the Central Provinces, but more is still required, especially in Nimar. Preparations for the rice crop have commenced. In the Punjab no rain fell during the past week, but prospects are on the whole good. Rabi operations have commenced in parts. Rain has fallen throughout the North-Western Provinces and Oudh,

but more is needed in places. Kharif crops have benefited by the rain, and harvest operations have begun in a few places. Prospects are on the whole good. In Bengal rain has again been general. Prospects of crops are good, except in the flooded tracts in the Burdwan and presidency divisions, in Behar, and also on the sea-coast of Orissa. Bhadoi crops, where not injured by floods, are being harvested with fair results. In Assam agricultural prospects continue favourable. Crop prospects are good in British Burma. The public health is generally fair. Prices are high in Bengal, and are generally steady elsewhere, except in Mysore, where they are rising slightly.

A CORRESPONDENT of the *Madras Times* brings to notice the merits of two native gentlemen, who have done a great deal in the cause of agriculture. This is what it says of one of them:—

"Mr. Sabapathy Moodelliar is a native of the Bellary district, and is well known as one of its very foremost citizens, as a man of education, wealth, energy, and intelligence; as a merchant and an advanced agriculturist. He has in his own hands upwards of 4,000 acres of land belonging to rayyets which he has taken, which he works with them, to which his capital has been applied. He has imported some 350 of the best pattern English ploughs; and practically shown their advantages: he has actually sold some 200 of these, while the others are used on his own lands. He has experimented with manures, and especially with pondrette, the whole outturn of which, I believe, he buys from more than one municipality. He it was who persistently followed out experiments in feeding cattle on prickly pear; and to this day he does so feed them partially, with the best results. He has employed a number of men trained at the Saidapet farm, and if we had not had such bad seasons, would probably have very much extended his operations. So he has started steam cotton presses all over the country. In eight of these he is interested, most, if not all, started by himself; he still manages, and is the leading spirit of, these all; they have, after their success has been assured, been formed into Companies paying good dividends. He was one of the movers, perhaps the chief, in the Bellary Spinning and Weaving Mill, where at present spinning only is carried on, and the management of which is now in his hands with the most satisfactory results; and he has another mill at Pondicherry, where both spinning and weaving are carried on. He has a distillery at Bellary, and also a small sugar factory, and he is largely interested in extensive sugar works at Panrooty in South Arcot. Above all, he is distinctly a man of the people, thoroughly trusted by them, thoroughly acquainted with their feelings and their wants."

(Of the other it is written:—

"He is an hereditary landholder in Tanjore, and is a Mirasdar in the Shiyall taluka of that district. His letters and reports which have been published by the Agricultural Department show him to be a man of considerable education, though not a 'Bee Yea'; and instead of following the usual role of zamindars, he has gone in energetically for improvements, in the carrying out of which he himself takes an active part. He has now some on 1,700 acres of land under his own system of cultivation, most of it with improved ploughs, which he at first got from Madras, but which he now makes on his own estates. He has started a workshop; trained artisans, whom he has taken round the best workshops in Madras; and now, he makes and repairs ploughs not only for his own use, but also for sale to adjoining landholders, among whom, I am glad to say, his spirited example is gradually having its natural effect. He also employs some of the trained men from Saidapet; he experimented (and continues doing so) with various kinds of manures; he has introduced on his lands a better class of cattle; has shown an example of great value by housing them properly, feeding them properly, and carefully looking after, and collecting in the best way their manure. He has started a machine for crushing oil cake for them, and is always ready to give a fair trial to anything that gives real promise of being successful and economical; while his experiments are carried out in the true and proper spirit, as may be seen from this short extract from a late report, at the end of which, he says, 'I beg to state that these cannot be taken as my conclusive opinions, since I am always changing them while my understanding of the matter increases.'"

The following is a summary of Messrs. Wm. Jass & Hy. Thos. Messrs. fortnightly circular of Indian tea, dated London, 10th September, 1885:—"Upwards of 55,000 packages have been

brought to auction during the fortnight, including 3,600 packages from Ceylon, and 1,500 packages of reprinted tea. A considerable portion of this has been tea of really fine character from Assam and Darjeeling, which from the lowest to the highest grade has met with keen competition, and has realized very satisfactory prices. Closing rates for fine descriptions are not quite up to the highest point, notably for Pekoes and Broken Pekoes, between 1s. 9d. and 2s. 3d. per lb. Teas with good make but indifferent liquor—in which category most of the Cachar, Sylhet, and Chittagong teas recently received are unfortunately included—become less easy to sell as supplies increase, and the weakness in quotations for common to medium Pekoes foreshadows a low range of price for these kinds later on. Leafy and broken sorts under 11d. per lb., however, are just at present an exception, as they are selling at stiff rates, the retailers having apparently come to an end of their stocks of cheap Souchongs and Brokenas. Considering the cheapness of China tea, between 8d. and 10d. per lb., it is hardly safe to reckon upon these prices being maintained; to some extent, however, they reflect the opinion of consumers as to the respective merits of China and Indian tea; for the relative value of the different growths depends almost entirely upon the balance of opinion among the mass of buyers throughout the country, by which the London dealers are guided in their operations. An illustration of this may be seen in the price of Ceylon teas, which continue to grow in favour, and to some seem dear in comparison with Indian: it is clear, however, that consumers who make the market think otherwise. We are unable to trace any change in the direction of a special demand for any particular type of tea; the highest prices, as we stated in our last circular, have been realized for the fully fermented, extra strong kind, and as successful instances of this type we must quote the teas just received from Amgoorie, Borelli, Jhanzie, Kellyden, Teek, and the Assam Company (not yet sold); but the prices obtained for the Chinamara, Meleng, Mijica Jan, Salolah, Scottish Assam, &c., and for the Ting Ling, Singbulli and Murnah marks among Darjeelings, show the strength of the demand for lighter teas with more flavour or pungency. The deliveries during August were again light, and from the figures overleaf, it will be seen that for the first three months of the season there is a serious falling off both in China and Indian. Taking the deliveries, however, from the 1st January—which includes the four months before and after the Budget—consumption of Indian and Ceylon has been 45,682,000lb., as compared with 41,190,000lb. during the corresponding eight months of 1884; and the delivery of China, &c., 100,880,000lb., against 102,100,000lb. At the Calcutta sales of the 27th of August, about 12,000 packages were sold at previous prices, the average being 9½ annas; and on the 3rd of September, about 14,000 packages were sold at 10 annas average, the market being quoted irregular, but generally ½d. to 1d. higher, a large proportion being Assam tea of good quality. The averages of the corresponding sales last season were 9.9 and 9.4 respectively. To-day 16,000 packages were offered."

**

MR. D. B. ALLEN, of the Bengal Agricultural Department, has addressed the following letter to the *Englishman*, on the subject of bones as a manure:—

Bones were first used as a manure in England about seventy years ago. At first they were ground, but after the method of dissolving them in sulphuric acid was discovered, the custom of using bone super-phosphate was generally adopted. It will probably be many years before bone super is commonly used in India, but it may be possible to treat bones in a cheap and simple way, which has more chance of becoming popular in this country. Putting aside caste prejudice, which is not an insuperable obstacle (for where labour is cheap, low caste men can always be employed to do the necessary handling), I come to the great objection that has been often urged, viz., the labour and expense of grinding bones sufficiently fine to spread evenly over the soil. This may be avoided by the process of fermentation. The value of fermented bones is recognised in England, and some farmers prefer it to super (*vide* the article on Agriculture in the *Encyclopædia Britannica*, ninth edition). This preference is not judicious; but experiments have proved conclusively that fermented bones give better immediate results than those obtained by applying bones raw, though the lasting effects of the latter continue for a greater number of years.

The process of fermenting bones is exceedingly simple. The bones, when collected, should be piled in a heap and mixed with half their weight of earth. The mass should be watered with urine or the liquid oozing from a dung heap, and then covered with a coating of clay about two inches in thickness. Strong fermentation will take place, and in three or four months the bone manure will be ready for use. It will be found especially valuable on light soils; and a good dressing of a ton to an acre will improve the crops for several years. The special value of bones is due to the phosphates they contain, and the experiment I advocate is so cheap and simple, that any one can prove for himself whether this system of manuring is advantageous or the reverse.

It must be remembered that the effect of bones, even when fermented, is not immediately apparent. As a rule the benefit of this manure will be seen better on the second crop sown after the manure was applied. Nor do I pretend that bones will give as valuable results as a general manure like cowdung. The value of cowdung is well-known to cultivators, and all that is not required for fuel is carefully stored and applied; but as cultivation increases, and the supply of cowdung diminishes, the necessity for some cheap substitute becomes more and more apparent. Bones alone will not supply this want, but bones and saltpetre will, I believe, except on lands naturally rich in soluble salts, afford the best substitute that can be got in India. Saltpetre alone will on some soils give marvellous crops, but this very fact tends in the long run to further exhaustion of the soil, unless other manures like bones are occasionally applied in order to maintain its normal fertility.

**

In the *Proceedings* of the Agri-Horticultural Society of India, 23rd September 1885, we find the following communication from Mr. J. A. Middleton, of Tinkong, regarding his experiments with economic plants at Tipling:—

"*Vanilla*.—I think I told you that I had planted it in virgin jungle with only the undergrowth cut down. It came on splendidly, but I regret to say that the squirrels took a liking to it and eat off the shoots as they came out. I have removed it to a more open space and have planted artificial shade over it, and I am glad to say it is now doing very well. Of course this transplanting has checked growth considerably, and will, I fear, cause delay in blossoming and fruiting, but I have little fear for it now.

"*Ceara Rubber*.—Last lot has germinated fairly well; after it is germinated it seems to have only one enemy, namely, the mole-cricket. This fellow destroys them when they are 3 to 4 inches high. I had 40 plants destroyed in one night. The only tree that came to any size here (Tinkong) out of the very first lot of seed you sent me, has begun to flower. I regret to tell you, however, that during a thunderstorm some two nights ago the flowering branch was broken off. This branch I have cut in pieces and planted to see if they will grow. In March one of the trees planted at Tipling was blown down in a gale. I had it cut in pieces and planted at once, and I am glad to say that all the cuttings are doing well. I should now be obliged by your giving me some information as to when, where, and how the trees ought to be tapped.

"*Diui Diui*.—As I told you some time ago the tree grows very freely here. Nearly every seed you sent me has germinated. The few trees I have here have not grown much in length lately, but have thickened about the roots, and have spread out on top. They seem to like the sun, as all are turned towards the south and south-west. Two are especially noticeable in that way, being spread out like trained plum trees facing south-west, not a leaf on the other sides. There is no shade anywhere near them, so I cannot account for this way of growing.

"*Rhea*.—I regret having forgotten to watch this plant at seedling time (end of April and May), as I wished to send you seeds. I was busy with a lot of new machinery and building at the time, and the Bangalore garden was rather neglected. I shall be very glad to send you a lot of cuttings if you wish them, and would try and remember seed next year.

"*Vegetable Seeds*.—When distributing the seeds I should like you to send all "*Bujis*" if possible. I find that they do best in Assam. For eleven years I have never had a failure with them, whereas even the best English seeds have never been a great success either with me or my neighbours.

"*Neem*.—This tree requires great care. I have been able to save three trees only, and would be glad of a few more seeds if you can spare them.

* American green seeds from R. Bulst, Jr., Philadelphia.

"I hope your remark that the Bengal Government are desirous of assisting the members of our Society for experimental purposes, as I shall be most happy to give every assistance in my power, and shall give any seeds or plants sent me my best care."

A short time ago we noticed the offer made by Mr. Nichols, C.S., to supply free of charge seeds of the "Katang" Bamboo (*Bambusa Arundinacea*.) In the *Proceedings* noted above we find the following letter from Mr. Nichols to the Society, and their comments on the subject:—

"I trust that a packet of Katang Bamboo seed will be despatched to-day to your address; you will, I believe, have nothing to pay, I shall be more than recompensed by your success. I venture to advise sowing in shallow pans or in seed beds in shelter. Transplant to a nursery bed when the seedlings are about two inches high. Again transplant when about seven inches high, and keep till finally located in a place where they can be frequently watered. The Katang likes a rather sandy alluvial soil, though it will do well on 'regur' or black cotton soil.

"So far as I can see, there will probably be no chance of getting more seed for some forty years. This variety is believed to have a life period of about 55 years. It often attains the height of sixty feet under favourable circumstances."

In 1886 Captain Sleeman recorded in this Society's Journal (*Transactions*, Vol. III) the flowering and death of all Bamboos in Dehra Doon, and states that it is a characteristic of the Bamboo that all the produce of the same seed will run to seed and die in the same season without reference to the season in which they may have been transplanted from original stock. Dr. Brandis seems to confirm this in his *Forest Flora*, and says isolated clumps may be met occasionally, "but as a rule all clumps in one district come into flower simultaneously, a few clumps flowering in the previous and some in the succeeding years." So it is probable that there will be a wide-spread flowering next season."

We also find the following regarding the *Erythroxylon Coca*, in the same *Proceedings*:—

Since the very valuable properties of this plant have been recognised, the utmost attention has been paid to its propagation at the Society's Garden, where a large plant some four feet high has long been established. Plants are now being distributed to members in selected districts for trial and report, viz., Darjeeling, the Terai, Cachar, Pubna, Tirhoot, Mussoorie, the Neilgherries, and Assam. In Bengal the plant seems to flourish without any special care or shelter, and seeds very freely.

GENERAL WILKINSON ON ENSILAGE.

II.

We now come to the practical results of General Wilkinson's various experiments. The silo, filled on the quick-loading system on 18th September 1884, was opened about the end of the year, i.e., barely three months after filling. We regard this period as scarcely sufficient to give anything like satisfactory results, nevertheless, in the present instance, the General assures us that the forage was "an excellent sample of ordinary wet sour silage, uniformly good throughout." The waste was limited in this case to two inches of grass immediately under the mats, though in places round the sides, especially near the door, the forage in contact with the walls was slightly mouldy; but exposure to the sun and air rendered the whole of this fit for use. An inch of water was found at the bottom of the silo, but this, it is said, had in no way injured the forage in contact with the floor of the building. Two other silos, one on the quick-loading, and the other on the slow-loading system, were opened in March last. We were ourselves present at the opening of these, and published a few short notes then placed at our disposal. These, however, gave very little information. From the report before us, it appears that "every blade of grass in both silos was in excellent condition, except that, as usual, the grass immediately under the mats had perished to a depth of not more than an average of 2 inches." It is further stated that, to decide positively whether the slow-loading system caused any destruction of fibre during the process of fermentation, thus causing loss of bulk in forage, one superficial yard was marked on the top of each silo, and the whole of the silage below it was cut out as carefully as possible down to the very bottom to

ascertain whether there was any marked difference in the weight of the two trusses thus obtained. The result was that the truss cut from the quick-loading silo weighed 1,004 lbs., while that from the slow-loading, 874 lbs. This difference in weight was, however, due to the fact of the latter silo having been built over a quick-filled one, which received the drainage from the slow-filled one. To arrive at an accurate estimate, a similar truss was cut from the quick-filled silo under the slow-filled one which weighed 1,135 lbs. Adding this to the 874 lbs. and dividing by 2, will give the average of 1,006 lbs. Thus it will be seen that slow-loading does not cause any diminution in the actual substance of the silage, while making it pack closer.

Referring to the space occupied by silage, it was found that the two slow-loading silos showed an average of 36½ inches of depth while the quick-loading was 46 inches with the same quantity of grass, thus showing 9½ inches more space in every 36½ inches occupied by the slow-loading method. General Wilkinson rightly says that "this is a most important fact, as the cost of masonry silos is the one argument against their universal adoption." The calculation made by the General as to the proportion of silage obtained from green grass is important. There were three silos, 10' by 10' by 10', each filled with 192½ maunds of grass. The average depth in the two slow-loading silos, as before said, was 36½ inches; and one square yard of this having been cut out down to the bottom, would give one-eleventh of the entire contents; and as each silo received 192½ maunds, or 15,400 lbs. [one maunds=80 lbs.], one-eleventh of this weighed 1,400 lbs. of green grass. When converted into silage, it weighed 1,004 lbs., having lost 396 lbs., or about 28 per cent in weight in both the quick and slow methods. General Wilkinson observes that there is every reason to believe that the whole of this apparent loss is due to the evaporation of excessive moisture; and that if the grass was cut on a dry day free from rain water, the loss in weight would be very small, probably less than 10 per cent. What he says about hay, occupying weight for weight six times as much space as silage, and about its containing weight for weight three times as much solid feeding matter, we remember to have read some time back in one of our English or American exchanges. It is further stated by the General that to those who have to purchase wet green grass by weight for their silos, it may be useful to know that, to estimate the amount of matured and sound silage, they must deduct about 28 per cent for dryage and 2 per cent for loss by rot and mould, or 30 per cent in all. But if only wet with dew, then 12 per cent. The following remark is important:—

"Silage weighs from 35 to 40 lbs. to the cubic foot, and one cubic foot is a full allowance for a large Hansi or English cow. Exactly one-half of this amount is sufficient for one of the very small village country cows, or for an ordinary agricultural bullock. So that a masonry silo 10' x 10' x 10' containing, say, 6 feet of good sound silage, will feed an English cow for 10 x 10 = 100 x 6 = 600 days, or a pair of country bullocks for the same period."

In England, it is said, well made silage weighs 50 lbs. to the cubic foot; but we suppose an extraordinary pressure would be required to bring this about. General Wilkinson's estimate seems a very fair one. We should like every cultivator to know that a silo 10' x 10' x 10' filled with 6 feet of silage, will feed a pair of bullocks for nearly two years. It would rather astonish the untutored ryot to be told that he could preserve his cattle fodder in a green state for a day of scarcity without any great trouble, risk or cost, sufficient to last him for his pair of bullocks for nearly two years! It is only by putting the matter before him in a plain, unvarnished, practical way, that our officers of the Agricultural Department can hope to effect any good among the cultivating classes.

Turning now to the nourishing and fattening powers of silage, we find that the figures quoted by us in April last in connection with these experiments were not quite as full as we have them in the report under review. To enable our readers to arrive at a fair conclusion, we quote this portion of General Wilkinson's report in extenso:—

All published statistics show, and my recent experiments fully confirm the fact, that silage is more easily digested, more nourish-

and fattening, than the green grass from which it is made. The accompanying table shows one of the advantages of silage:—

Statement of feeding and weights of four Orissa Bullocks fed on silage and four fed on ordinary rations from 29th December 1884 to 14th February 1885.

Four bullocks fed on ordinary rations.		29th December 1884.	30th January 1885.	7th February 1885.	14th February 1885.	Increase.	Decrease.
Paddy straw, dry grass & rice.		lbs.	lbs.	lbs.	lbs.	lbs.	lbs.
Ordinary rations.	at 25lb daily	1,024	1,020	1,021	1,020	..	4
	at ditto	1,000	1,005	1,008	1,108	12	..
	at ditto	947	1,003	976	974	27	..
	at ditto	1,000	1,100	1,000	1,104	25	..
Total		74	4

Four bullocks fed on silage.		29th December 1884.	30th January 1885.	7th February 1885.	14th February 1885.	Increase.	Decrease.
Green grass & rice.		lbs.	lbs.	lbs.	lbs.	lbs.	lbs.
Silage.	at 25lb daily	1,185	1,185	1,100	1,104	6	..
	at ditto	984	1,026	1,030	1,030	46	..
	at ditto	1,108	1,187	1,110	1,140	32	..
	at ditto	1,070	1,108	1,100	1,108	38	..
Total		122	..

N.B.—Paddy straw is so bulky for its weight that 25lbs. of it is considered by Government to be equal to 35lbs. of any green forage.

Six cows were experimented on—two of them large Haasi animals, letter A and B, and four small country cows numbered from 1 to 4—

Six cows, all fed on green grass up to 1st November 1884.		1st November 1884. weight.	Weight on 1st December 1884.	
		lbs.	Fed on grass. lbs.	Fed on silage. lbs.

ditto	408	..	458	..
Total	1,445	..	1,535	..
Total gain on silage	210	..

Letter A cow had been recently purchased in poor condition, so that it was still putting on flesh rapidly when these experiments began, or they would have been still more favourable to silage.

The silage used in all of these experiments was made on the quick loading system. The grass from which it was made was the common "alu" of Bengal (*Imperata arundinacea*), one of the poorest forage grasses in India.

We direct particular attention to the opening paragraph of the foregoing quotations. It will also be seen from the figures that the advantage was all on the side of silage. We regard these results as conclusive; and it is difficult to understand how any one could, after studying these results, come to any other conclusion than that silage was superior to fodder in a green state. It is true that in the feeding experiments with the cows, the General has omitted to give us the respective weight of silage and green grass upon which they were fed; but it may be taken for granted that they received fodder of both kinds in the same proportion, or based on the same calculation, as that given to the bullocks.

General Wilkinson observes that very recent experiments with silage made from the same grass on the slow-loading system, have not given good results, the animals losing weight when fed on it. He therefore does not recommend this system for general use. This is an important point, and should be noted carefully by those engaged in ensilaging fodder. We ourselves fail, however, to account for this result, as the silage

was of the same kind. But practical testimony ought to go a long way towards establishing a fact.

We find also that three Government bullocks in poor condition and at constant work, when fed on silage for one month, showed a total increase of 132lbs. Similarly, six other bullocks, all in the sick lines suffering from chafes, &c., were fed on half silage and half paddy straw for one month, and showed a total increase of 560lbs. or an average of 96lbs. The silage in both these instances was made from the common *alu* grass on a quick-loading system.

Looking at the experiments in the quality of milk, we find the same advantage on the side of silage. The milk was first tested with the cream, i.e., fresh from the cow, and afterwards in its skimmed state, 14 hours after. The General says: "All cows (at any rate in India) yield less and less milk, and their milk gets poorer as their calves get older. Native cows generally cease to give any milk about six months after the birth of a calf. A different opinion has, however, been expressed by a gentleman who has graduated at the Cirencester College; but having had some experience in India ourselves in dairy farming, we are in a position to corroborate generally the opinion expressed by General Wilkinson. The milk is "thin" and poor for a week or so after the birth of a calf; but improves steadily for about three months, after which it begins to get "thin" and poor, and deficient in quantity during the next three months, after which it ceases as a rule. There are exceptions of course, and we have known Haasi cows in the Hariana district to give good milk for 8 and 10 months. This was noticed by us in the case of cows kept at the Hissar cattle farm; but they were exceptionally fed and cared for, which is not the case with the great majority of cows in India. We take one more long extract from the report under review, as follows:—

The effect of this forage on the quality of the milk was, however, very marked, the use of silage almost invariably improved the quality of the milk to a perceptible degree, and the lactometer showed that the increase in cream was often very great.

The following table records the result of observations extending over six periods of 15 days each, commencing on the 1st November 1884. Six cows were experimented on, and the first six lines in the table show the result when these were fed upon green grass, chiefly *alu*. The silage was made from the same sort of grass on the quick loading system.

It will be seen that as time went on the "figure of merit," that is, the figure recorded from observations with the lactometer gradually sank, so long as the animals were fed upon grass.

The last six lines of the table show the result when these same six cows were fed on silage. It will be seen that the decrease in richness that was to be expected as time went on and the calves got older was greatly retarded, and in some cases the milk was considerably richer at the end of the experiments than it had been at the beginning:—

Richness of milk tested at periods of 15 days.									
Number or letter of cow.		First period.	Second period.	Third period.	Fourth period.	Fifth period.	Sixth period.	Remarks.	
Fed on grass.	Haasi cow A.	12	11	9	Put on silage.	..	Loss 2 1/2 p.c.
	ditto B.	10	10	10	Silage.	0 1/2	Loss 3 1/2 p.c.
	Country cow 1.	10	10	10	Silage.	0 1/2	Loss 3 1/2 p.c.
	ditto 2.	10	10	10	Silage.	0 1/2	Loss 3 1/2 p.c.
Fed on silage.	Haasi cow A.	12	On grass.	18	Put on grass.	11	Gain 2 1/2 p.c.
	ditto B.	10	On grass.	18	Put on grass.	11	Gain 2 1/2 p.c.
	Country cow 1.	10	On grass.	18	Put on grass.	11	Gain 2 1/2 p.c.
	ditto 2.	10	On grass.	18	Put on grass.	11	Gain 2 1/2 p.c.

The General thinks that to obtain the best results, the forage should be freshly cut and wet with rain or dew. He does not advocate the addition of salt; and recommends that silage should be cut out with a big knife in the same way as a stack of hay is cut at home; and that it is advisable to stack it in the air, sun, or wind for a few minutes before offering it to cattle. It is to be understood, as a matter of course, that the better

the grass the better the silage," and the better the silo, the better will be the results, as there will be much less loss from rot or mould.

Reviewing the three kinds of silage, the General confidently recommends the quick-loading. He says: "It never fails, and the results of all my experiments are entirely in its favour. If made of good grass, cattle prefer it to all other forage, and thrive and improve on it in an astonishing manner." With regard to the slow-loading method, he observes:—

"It appears in every respect exactly the same as quickly-loaded silage, except that it is more tightly compressed in the silo. The result of the feeding experiments with it, however, have been most disappointing. I therefore cannot recommend it. Further experiments may show that this failure was not due to the system, but still that is proved I strongly recommend that the quick-loading system be adhered to. It has yet to be proved that sweet silage has all the fattening, nourishing, and milk producing powers of sour silage."

He is somewhat diffident about expressing a decisive opinion in respect to sweet silage, for he says:—

"I have not sufficient experience of sweet silage to recommend it. Cows A and B have been fed on it for three weeks, and continue to give good rich milk, but the quantity is decreasing, probably because their calves are fully eight months old. The system is a troublesome one, and could never be generally adopted."

We, however, do not agree in the opinion that it could "never be generally adopted." The trouble is very little more, and we have every confidence that time will prove sweet silage to be the "silage of the future."

The following remark, regarding the grass found by him in the Fort, is important:—

"In Bengal I think the grass recently found by me in the ditch of Fort William should be sedulously spread throughout the country. It is not only one of the best forage grasses known in the world, but it is particularly suitable for horses and cattle; it resists drought, flourishes in Bengal, and can be kept in stock for 10 or 12 years. This is just the grass that is wanted in India and particularly near sea ports and great centres, as it could be collected in stacks and kept as a grand forage reserve in case of war or famine."

The grass referred to is the *Andropogon pertusus*, which is also known under other synonyms, such as *A. punctatus*, *Holcus pertusus*, *A. annulatus*, *Loposperma pertusus*.

In conclusion, we have only to say that one such experiment as that conducted by General Wilkinson, proves more than all those carried out by district officials, and which we have from time to time noticed in these columns. These were—we have no hesitation in saying it—in every instance worthless; and it is a pity that the Government of India ever permitted them to be carried out. So far as we can make out, the General has left no point unnoticed. The experiment was thorough, and he deserves great credit for the exhaustive, painstaking, and laborious manner in which he has drawn up his report. He has done a real service to the country in a most important matter of agricultural economy, which should be duly acknowledged by the Government of India.

THE IMPROVEMENT OF SEED CORN.

[Communicated.]

Some few years since the Council of the Royal Agricultural Society, with the view of stimulating the production of improved varieties of wheat, opened a series of prizes, and although after protracted and exhaustive trials, the judges appointed by the Society were not unanimous in admitting that any of the varieties submitted in competition were distinct from sorts already in cultivation, there were two kinds selected as being far in advance of the others, and considered of such sterling value as to justify special recognition in the shape of silver medals. It was the subject of this competition that suggested to Messrs. Carter, seedsmen, of High Holborn, London, the desirability of conducting some thorough experiments, with the object of artificially classing some of the most popular varieties of wheat. An account of these experiments may perhaps prove of interest to the readers of the *Indian Agriculturist*. The autumn of 1883 saw the commencement of

the process, by the sowing of the finest samples that could be obtained, with the object of having the very best blood to commence with. In the spring of 1883 some twenty or more crosses were made by one of Messrs. Carter's professional experts at their Experimental Grounds at Forest Hill, under the personal guidance of Mr. Sharman, the Manager. It may be noticed here that in the opinion of these experimentalists, natural cross fertilization of wheat, i.e., the impregnation of the pistil of the wheat flower with other than the pollen produced in the same flower, is physically impossible; and the process can only be made successful by the most careful and practised expert. The grains upon which the fertilization had been effected were carefully harvested, and in the autumn of 1883, sown side by side with either parent. By this means the most thorough comparison could be made, and peculiarities discovered. In due course of time, it was observed at a very early stage of growth that in several instances the effect of hybridisation had been successful, inasmuch that the hybrid, or the child so to speak, instead of having the upright habit of growth of the female parent, would have the prostrate and peculiar drooping form of the male, and vice versa. In some other cases, the offspring has the smooth chaff of the male, whereas the female form has the peculiar woolly chaff well known form of some kinds of wheat.

Another noteworthy instance of the direct result of hybridisation is shown in No. 19 (which is described further on), where the female is a woolly-chaffed, short-strawed wheat and the male is a very large, bearded and tall American variety; the offspring in this case is about a foot taller than the female, the chaff is more or less smooth, and the thick-set ears bear minute awns at the apex of the chaff of each grain in the tiers which appear to greatly puzzle the birds, and is known at present by the name of the bird-proof variety.

Another remarkable result is No. 13, the female parent being the well-known early Talavera.

It is expected that the hybrid in this case will prove of inestimable value for sowing in those countries where the seed time is in spring, and where earliness is an important desideratum, inasmuch that after careful personal observation, we have been able to confirm Messrs. Carter's own experience that the hybrid ripens, and is fit to harvest fully 14 days before either parent. This peculiarity was observed in the trial of last year, and this season's results fully confirm it. The ears are much finer and the grain appears to be greatly superior to the American dultuth; it is also quite a fortnight earlier than that well-known American variety, hitherto considered the earliest variety in the United States.

It is the custom, we believe, for English millers to mix a certain proportion of red wheat with imported whites with the object of giving substance to the flour, and Messrs. Carter with this fact in view have used red and white varieties of wheat in several instances as respective parents. Up to the present time the limited quantity produced in the experiments has not admitted of any of the hybrids being submitted to milling experts, but bearing in mind that only those varieties of wheats that are already known and liked by millers have generally constituted the parents, that the milling value will be great may be accepted as a foregone conclusion.

Various peculiarities are shown in the hybrids. In one instance extreme earliness, in another immunity from damage by birds, in another firm setting of the grain and non-liability to "thrash out" on the land during the prevalence of windy weather, a desideratum of the utmost importance to the New Zealand wheat-producer who leaves the grain until it is dead ripe, cutting off the ears almost close to the base and leaving the long straw to be worked into the land.

Another variety is remarkable for the short, thick, and firm nature of the straw. This appears to be a wheat that the heaviest torrent would fail to "layer," and is especially adapted for poor or very cold wet soils.

One feature is apparent throughout the trials, and that is, the remarkable vigour and productiveness of one and all of the hybrids as compared with the parents. This is the more remarkable, as in this season's trials which we had several opportunities of inspecting, the offspring has had the middle position in the plots, the parents as we have before

stated being sown on either side, and a broad path left on either side of them again for the greater convenience of observation, so that the parents had the advantage of more sun, air and light; yet, notwithstanding these manifest advantages, the hybrids are immensely more vigorous and productive.

It should be mentioned that the cultivation was alike for all, and was not by any means high; and an equal number of grains were sown in each instance throughout, so that this comparison in regard to productiveness is very reliable.

As an instance of the remarkable vigour of the hybrids, we were shown one plant in the row (No. 9) having 60 distinct ears; these are very long and well filled averaging 50 grains per ear, and the entire plant the produce of one grain showing a produce of 3,000 grains or 3,000 fold.

We have also had an opportunity of examining the ripe corn, when the distinctive features indicated by the habit and peculiarity of the plant is confirmed by the varied form and colouring of the grain.

It is upwards of 30 years since any records were made of the hybridisation of wheat in this country (England), and it was then that Mr. Shariff succeeded in developing some important improvements in wheat corn.

The following varieties have their distinctive character so fully developed, that Messrs. Carter have determined to cultivate them in larger quantities the ensuing season, with the object of placing them in the hands of the public as soon as possible :—

Hybrid No. 18.—Sown November 19, 1884.

Height of female, 4ft. 6in.

" " hybrid, 5ft.

" " male, 4ft. 9in.

Talavera White, crossed with Carter's Royal Prize Red.

Female, in ear, June 11.

Hybrid " " "

Male " " "

The advantages claimed for this hybrid are very broad ears partaking prominently of the character of the male parent, a very early and wonderfully quick ripener, being fully matured quite 14 days before either parent.

Hybrid No. 19.—Sown November 19, 1884.

Height of female 4ft.

" " hybrid 4ft. 9in.

" " male 5ft.

Carter's Fifi measure, crossed with Mammoth White.

Female, in ear June 19

Hybrid " " "

Male " " "

The female in the early stage of growth is dwarf and prostrate, while that of the hybrid is upright, after the style of the male; in its maturity it nearly approaches the height of the male parent; the ears are more bearded than those of the female and not so woolly; they are thick and closely set; the spiny beards are a great protection from birds; ripens 10 days earlier than either parent. Harvested August 22nd; considered a most distinct cross.

Hybrid No. 10.—Sown November 19, 1884.

Height of female 4ft. 6 in.

" " hybrid 5ft.

" " male 4ft. 9in.

Square-headed White, crossed with Hunter's White.

Female in ear June 18.

Hybrid " " "

Male " " "

Although it will be observed the hybrid was six days later in flowering, the ear was dead ripe six days earlier than either parent. The straw of this hybrid is of splendid quality, and would gladden the heart of the most exacting barnet builder, and the wheat appears specially adapted for light dry soils; one of the plants carried 40 ears, thus showing an immeasurably superior productiveness to either parent.

The male parent is very apparent in the hybrid in length of ear, but the most bright coloured straw takes the form of the female—ears narrow, very long, and well filled, 10 tier, 3 x 4 grain.

ROYAL BOTANIC GARDENS, CALCUTTA.

THE following resolution of the Government of Bengal contains a summary of the work done in these gardens during the year 1884-85:—The unusual mildness of the last cold season exerted a favourable influence on the more delicate plants cultivated in the conservatories, while the show of orchids was the most magnificent that has been seen for many years. A large number of the numerous trees planted during the past few years have grown well, and the garden now presents a fine park-like appearance, for which the public of Calcutta, no less than the Government, are indebted to Dr. King.

The cultivation of several economic plants engaged the attention of the Superintendent during the year. A fresh attempt was made to introduce the plantain (*Musa textilis*), from which Manila hemp is derived; but, as on previous occasions, the cold weather proved fatal to every plant of this species. Of the *Rhea* plant, both stems and roots were distributed among persons interested in discovering a proper method of extracting the fibre. Another fibre, which has lately attracted considerable attention, is bow-string hemp, the product of the plant *Sansevieria Zeylanica*. Although not indigenous, the tree grows well in Bengal, and the fibre is said to be admirable, while it is easy of extraction from the plant. Dr. King reports as follows on the Japan paper mulberry :—

"In several of my recent reports I have referred to the Japan paper mulberry as a hopeful source of paper fibre for Bengal. I am happy to say that the trees of this species in the garden continue to grow well. Although now only three years old, they are twenty-five feet high, and have proportionately thick stems. The fibre contained in the bark is one of the best materials for paper known. It is easily separated, is strong, and requires little bleaching. As the tree grows thoroughly well and coppices freely, I think it quite possible that, in the course of time, natives may be induced to grow it on the odd corners of land which are so common near Bengali villages."

The *Sabal* grass, the suitability of which as a raw material for paper has been established beyond doubt, is now largely used in local manufacture. Attention has lately been given to an important alkaloid, called cocaine, which is extracted from the leaves of the cocoa plant; and this plant is now being propagated to a large extent for distribution.

There have been considerable additions to the collection of dried plants, the contributors being Sir J. D. Hooker, Mr. Kunzler, Mr. Gamble, Mr. Duthie, Mr. Talbot, Dr. Cook, and several others. The interchange of seeds and plants went on actively during the year, the issues amounting to 23,433 living plants, and 2,979 packets of seeds; and the receipts to 12,055 living plants, and 1,201 packets of seeds. The receipts from sale of surplus plants amounted to Rs. 1,075-11-6.

The *Lloyd Botanical Gardens, Darjeeling*, which had suffered severely in recent years from the depredations of cockchafers, grubs, were comparatively free from this pest during the year under review. The grub has gradually disappeared, and the garden has once more been stocked with varieties of plants. It is to be hoped that the grub, which is said to be extending its ravages in the Darjeeling district, will display no partiality for tea. Dr. King states that there is some possibility of the site of the old municipal vegetable garden, situated between the Eden Sanitarium and the Botanical Gardens, being used either for dhobies' huts or washing tanks. The Lieutenant-Governor considers that this would be most undesirable, and trusts that Dr. King may be able to make some arrangement with the Municipal Commissioners to prevent it. A special report on the subject should be submitted.

The thanks of the Lieutenant-Governor are again due to Dr. King and his subordinates for the excellent work done during the year. For the first seven months of the year Dr. King was on furlough, and his duties were carried on by Mr. Brace, the Curator of the Herbarium.

DON'T DIE IN THE HOUSE

"Rough on Rats" cleans out rats, mice, beetles, cockroaches, flies, ants, insects, moths, chipmunks, gophers.

A. W. Mason & Co. Calcutta, Sole Agents.

Miscellaneous Items.

The representative of the Bombay Exports at the Poona Fine Art Exhibition says:—"The pottery ware exhibited by Mr. Terry from the Art Pottery Works, Bombay, attracted considerable attention, as also did a few exhibits from Madras sent by Mr. Chisholm as the result of experiments conducted with indigenous materials. I was enabled to compare two fragments of the Bombay and Madras pottery, and found the latter a much closer grained ware. Although I am credibly informed that the two vases are made from exactly similar clay, I can scarcely believe it, there being such a difference between the spongy Bombay production and the hard, close pottery sent by Mr. Chisholm."

MONTAGU CLYMENT THOMAS, the Chief of the Service at Chandernagore, reports that the torrents of rain which fell unevenly at Chandernagore, from the 21st to the 25th August, caused considerable damage, especially to the Indian part of the town, and among the dwellings of the poorer classes of natives. The damage to public property is estimated at 5,000 francs, and the Mayor urgently demands 8,000 francs for the immediate relief of the sufferers by the floods. The Governor of Pondicherry has devoted 8,000 francs out of the subvention of 500,000 francs, voted by the Chambers on account of the inundations at Pondicherry and Karikal in November and December last, for distribution amongst the more pressing and needy cases at Chandernagore.

SOUTH AUSTRALIA is passing through an unexampled period of depression. Never before in the history of the colony has the number of emigrants exceeded the number of immigrants. During the first six months of this year, however, only 3,591 people went to the colony as compared with 8,571 who left it. Some anti free traders have been unduly exalting protection as represented by the sister colony of Victoria, and have asserted that this protection has attracted the people from South Australia, where free trade exists; but the examination of statistics showed at once that this was a fallacy. South Australians are content to wait for a turn of the tide, considering that the adoption of empirical remedies must aggravate and not remove the evil. Meanwhile, "intending" emigrants must remember that depression is felt beyond our shores.

THE Mysore Dewan has sanctioned the introduction of the Arabian date tree, which is to be cultivated as an experimental measure in the province. Steps have been taken, through the British Consul in the Persian Gulf, to obtain a supply of the proper variety of the date palm, and it is expected that 400 or 500 young shoots will arrive shortly. The date palm, which grows luxuriantly in localities that have a scanty rainfall, will, it is hoped, do well in the Chitaldroog and Kolai districts and part of Tumkur, where the rainfall is precarious, and far below the provincial average. Should the experiment turn out a success, and the cultivation be largely extended, it will prove a stand-by in times of scarcity. Old records show the Arabian date flourished in the Lal Bagh many years ago, but the trees were either cut down, or allowed to perish from neglect.

NOTWITHSTANDING the heavy fall of rain recently in Bangalore, the prospects of the season in the province seem as desperate as ever. The fall appears to have been local, and from all directions the cry of threatened famine continues to come. Kolar will suffer in particular, the crops having all perished, and rain still holding off. In truth two successive seasons of drought have already told on the district, and emaciated subjects, suffering from want of food, may be seen about the country. The Dewan, it is understood, has determined to face the impending disaster, and is working with the Resident measures for mitigating it as much as possible. Relief works will be immediately started in the worst affected parts. Remissions of assessment must of course be liberal, and the whole result will be a black look out for the Mysore exchequer.

THE annual Administration Report of the Department of Horse-breeding Operations for 1884-85 shows the total number of stallions to have been 79 at the end of the last official year. Out of this 6 died during the year under review, 6 were destroyed, and 9 sold as being unfit for stud purposes. The number of new stallions that was received amounted to 15, one of them being presented to Government by Major-General Gage. This left 79 at the end of the year 1885. Eight of these were European, 10 British, 10 American, 10 Australian, 10 Indian, and 1 Australian. Out of

these one only has turned out bad, and two others had not been judged. Of the rest, numbering 72, some of them are pronounced good and some fair, though the animals of the latter class are said to have become too old for stud purposes. The last lot has, since the close of the year, been ordered to be sold. These serviceable stallions have been distributed over Gujarat and Kattywar, Sind, and Cutch, and Beluchistan, but mostly in the Deccan.

ENSILAGE AT THE ROTHAMSTEAD LABORATORY.

SIR,—Being questioned during the autumn of 1882 by numerous correspondents as to the nature of the several chemical processes through which green fodder passed in its conversion into ensilage, I replied, both publicly and privately, that, being no more than a very humble observer, taking notes of plain facts that came under the observation of practical experience, I could not venture on the domain of chemical research; but I added that I felt assured of the speedy accession of scientific inquiries to aid in fixing the position to be taken by the new cattle food at that time just presented to the agriculturists of Great Britain. Truly the foregoing forecast has been abundantly fulfilled, for each succeeding season has furnished us with a number of analyses by eminent men throughout the country.

Committees, too, appointed by bodies having more or less authority (the most recent being of 'quasi' Governmental creation) have investigated the subject, and the whole series of such inquiries have culminated in the issue of a set of very interesting statistics from the pen of Sir John Lawes. The word 'culmination' is used here because to many agriculturists it appears a strange eccentricity of fate, that from Rothamstead, of all places in the world, should come a report that could in any way be construed as supporting the new system. Has it not become almost a household word that the eminent directing mind at this famous spot positively banned the whole thing in its infancy as being a sort of 'will o' the wisp' kept dangling and dancing over the morass of depression to the misadventure of the already too much distressed British farmer? Sir John's former outspoken opposition is here referred to with the most respectful deference, and is only alluded to, to demonstrate the fact that ensilage is possessed of a feeding power the position of which, in comparison with other foods, has been fixed by him with severe impartiality, and that we must surely be justified in taking his results as a basis of unquestionable authority from which to proceed with further inquiries. The sun and substance of Sir John's labour may be taken to be that ensilage can fully hold its own with mangolds and the best of other foods for feeding and fattening purposes, but that for the production of milk the other foods have by a small fraction the best of the title. Now, Sir, what I particularly wish should be made known as widely as possible is the important fact that the above decision virtually places all consumers of heavy land almost on an equality with their more fortunate brethren on light soils, and that a succulent, nutritious winter feed is now possible to be obtained by every farmer in the kingdom.

There are many plain, plodding, practical laymen who thoroughly believe in the outcome of scientific investigation, but yet cannot help feeling that in all such inquiries some important points or ideas are often omitted. Probably this is unavoidable, but to the mind of the practical observer every important subject is tinged round with others, of less importance doubt, but still bearing with more or less force on the central question. To illustrate what I mean, we will take one, only one, of these secondary affinities to the main subject before us. Sir John Lawes, in experimenting, pitted mangolds in combination with other foods against ensilage in combination with other foods. So far so good. But I venture to think it would have been highly interesting if he had set one against the other—each entirely by itself. Thus we would have had given a diet solely of mangolds morning, noon, and night for one, two, or more weeks consecutively—nothing else given but water and ensilage, dealt with in the same manner. If a course like this could be followed out, something instructive and interesting would almost certainly be learned therefrom.

Experience here with ensilage has now extended to four seasons. Our doings during the first two of these were frequently laid before the public. As, however, by the end of the second season when and more able pens in large numbers took up the refrain, we gladly turned into silence, feeling assured that the system, if

allowed a fair field, would hold its own. Mr. Stobart (the owner of this estate) continues to hold the same favourable opinion of it that he did at first. In 1884 he had, and again this year he has, in his silos upwards of two hundred tons of ensilage, and he is content in the assured feeling that he has in store something that will successfully meet the exigencies of the coming winter, as far as these are connected with his herd of cattle. Each winter he feeds upwards of 40 fat beasts, makes from 16 to 20 cows, and carries through upwards of 60 store cattle of various ages, and all of these, without exception, have a share of the ensilage.

Having been frequently asked to give an opinion as to how heavy arable land could be best utilized for this work, I should be glad, with your kind permission, to describe what Mr. Stobart has done this season with some 7 acres of fair average heavy land. Early in April this piece of land was sown with oats; on the 30th of July and August they were cut and put into the silos. During the following week the land was mowed and ploughed—the plough used being Ramsden & Son's 'patent chill-breast digger.' (This implement does its work splendidly, laying up and breaking the soil as if done by hand labour; indeed, so well does it perform its special work, that if better known it would surely become indispensable on every heavy land farm.) The usual course of harrowing, &c., has followed the ploughing, and the land is at the present moment a good fallow, ready to be ridged up for autumn sowing.

Thus Mr. Stobart has secured a crop and made a fallow in one season, where, under ordinary circumstances, the oat crop must have been taken now, and the fallow made next summer. It may also be noticed, in this connection, that silo crops are taken when in a green state, and are, therefore less exhaustive to the soil than if left to ripen.

When silos were first introduced into England the late cycle of rainy seasons were at the height of their baneful influence, and it was generally allowed that the crowning benefit of ensilage was to consist in counteracting the disastrous effects that so much wet produced on the quality of hay; but last year and again this year the drought is teaching us the additional important lesson that ensilage can prove as great a boon in dry seasons as in wet ones. On much of the tract of land which it is my duty occasionally to traverse, I find the turnip crops are virtually a failure. Almost every attempt has resulted in disappointment. Look, for instance, at that field before us, and on the majority of farms you will find its exact counterpart.

What does those ragged rows of stunted, aphid-covered, sickly-looking plants represent? Why days and weeks of heavy and painful drudgery to man and beast, and a heavy outlay of capital—the result to the husbandman being loss and disappointed hopes. He must, in consequence, also look forward to the almost certain selling (at a sacrifice) of the best of his store stock; and those calving cows also which the wife had quite reckoned on having to make butter from during winter—must they go too? While, on the other hand, happy is the man who in such a case has a well-filled silo to fly to. With this succulent, nutritious store at hand from which to draw at will, he can possess his mind in peace; for has he not the judgment of the highest authorities connected with the science of agriculture as a guarantee that good ensilage is fully equal to mangolds as food for his cattle?—Yours, &c.,

THOS EASDALE.

Estate Office, Pepper Arden, Northallerton,
September 5, 1885.

—North British Agriculturist.]

A FINE COS LETTUCE.

TO THE EDITOR OF THE "PIONEER."

SIR,—In the Lucknow Horticultural Garden is grown an acclimated cos lettuce, with a selected pedigree of upwards of 15 years. No newly imported kinds come up to it, as far as suitability to this climate is concerned, yet it is hardly known beyond the sphere of official reports. It is a large and tall cos variety; the tips of the leaves cabbage or fold over each other, so as to blanch the inner leaves, without the bother of swathing. Please note what those who have tried it have said about it. Some years back a trial of the Lucknow cos lettuce seed was made at the Saharunpore Botanic Garden, which resulted in the following report: "A splendid variety; three sowings were made, and all made heads superior to any imported variety we had. Enquiries were made by parties who received it in *dallees*, where the seeds were obtained from." (1) In 1868 I sowed some seed of this superb cos lettuce in Etawah, and sent some heads of it to friends. They said they never saw anything like it for size, whiteness, sweetness, and crispness. Last year I grew it again. I sent a few heads of it to a lady who had come to Etawah. She said she never saw anything so good. On returning to Agra she asked me to send her some heads of this lettuce, that she might show the residents of Agra what fine lettuce ought to be like in India. Later on she did not forget to write for some of its seed. Now there is a little secret about growing lettuce for seed, which may not be generally known, and which the sooner it is learnt, the more easily will the grower be able to improve his seed for future sowings. First, always get hold of the best acclimated strain possible.

Second, sow the seed, not too thickly, in well prepared beds of rich soil, in October (in the N. W. P. and Oudh.) Third, when big enough to handle prick out the young plants carefully 12 or 18 inches apart, in rich soil of the best quality, where they can get plenty of air and sun. Water at once with a rose, and then irrigate the beds regularly at intervals, and watch the result. The growing lettuce should never want water, that is, it should never be checked in growing; being a leaf-vegetable, it should have the richest possible soil. Of course weeding and other culture must be attended to. Chauli ashes appear to suit lettuce, but of course it is possible to give too much of a good thing. When the heads are coming on towards being fit for the table you will find that most of them will fold the tips of their inner leaves one over the other, that is, they cabbage. These are the ones you should select for seed. Do not fancy for a moment, however, that you lose the heads for the table by keeping seed from these plants. Note this. When the head is ready for use, cut it off close to the ground, leaving only three or four leaves on the stump. Plunge the head in clean fresh water at once, and use it afterwards as required for salad. Within a week or so you will see little sprouts coming up from the stump. These are the side shoots of the lettuce, and it is from these only that good seed for the next generation can be obtained, that is, if you wish to have lettuce that will grow slowly and cabbage, and will not "run off into flower like rockets." Please note also the following:—Any lettuce heads which do not cabbage and remain open like endive, take up scrupulously by the roots and do what you like with them. This you must see done yourself, as your males will not do it, but will leave the stumps of the open-headed lettuce, also in the ground, the shoots of which would seed like the rest and leaven and spoil your stock with lettuce fit only for cows and goats. The stumps, with their flowering stems, should be irrigated regularly as before until you gather all the seed you want. Remember the seeds, when ripe, are attached to little tufts of cotton, and will be soon blown away anywhere after expanding. They should therefore be collected daily, after the sun has dried off any dew. A second selection may be made while the flower stems are growing. The fewer stems you leave on each stump, the more nourishment will they get and the stronger will the seed ultimately be. The stumps of the earliest heads taken off *cat-via paribus* are likely to give better seed than the latest. The former will have a good bit of the cold weather to grow and perfect themselves in, while the latter will have the beginning of the hot weather to do it in. Yet a third selection may be made. By winnowing the seed, after cleaning it in a gentle breeze, over an extended sheet, you will be able to separate the plumpest, and therefore the soundest and heaviest seeds from the chaffy, light ones; the former is what you should keep for stock. If you follow this advice strictly, and see to it now and again yourself, you will not be disappointed with your acclimated seed. Moreover, by growing already acclimated seed and keeping your own every year, this lettuce will adapt itself, with a little intelligent modification in the treatment, to all the climates of the N., S., E., W., and centre of India. One word more about the seed. As it would be useless to go to war without keeping your powder dry, so would it be useless to take all the foregoing trouble about nursing and selecting it, after all, you do not keep your seed dry. Bottles well corked or tin boxes with tightly fitting covers—never too full—are the best for keeping seeds in. Take advantage of dry bright sunny days to air and sun your seeds on a blanket spread on a charpoy (not on the ground), with a boy to watch the squirrels. Now there is a reason for most things in this world, and the reason why the side shoots of the lettuce plant are better than the main shoot for keeping seeds from in India is this; the main stem tends to shoot up quickly, and the seeds will produce plants with the same tendency. Therefore lettuces from the main stem seeds would disappoint you by flying off like rockets into flowering stems before you would have time to consume them, and on the slightest provocation from warm weather and dryness at the roots, while your object should be to make them grow slowly, and have them fit for the table throughout a longer period. This you can bring about by keeping seeds from the side shoots only, which will give plants that will grow more slowly. Remember that the winter in India is very short; no sooner are you rid of the rains and their hot-house atmosphere than the coldest part of the winter is upon you (when most vegetables are at their best), and the next warm weather soon following up. Curiously enough, natives do not care about lettuce, although they who are fond of eating raw vegetables might eat the raw blanched and sweet leaves with advantage, especially if they first dipped them in lemon juice and then in salt. I use this fine cos lettuce, however, every winter for prisoners, while I keep the stumps of the prime ones for seed. In the prison the lettuce are sharpened and boiled as other vegetables, and a fine thing they make when properly done up. For soldiers nothing could be better than this fine vegetable. Last of all it is not impossible that this lettuce grows largely without much richness of soil would yield an opium called *Lactucarium* which is useful in medicine. It is collected from incisions in the lower stalk, and the root is said to yield an extract which is stronger than that made from the leaves. The medicinal properties of *Lactucarium*, or the extract, are said to be sedative, narcotic, gently laxative, and powerfully diuretic. Whether the cultivated kind can be made to yield this apparently useful drug is, however, a matter for experiment.

E. BONAFIL.

ABOUT THE SUNFLOWER.

Some few weeks ago we were sitting with some "old reliable" farmers, talking over different methods of farming and new crops. The conversation turned to the subject of sunflower culture for stock and poultry feeding, and we concluded to give our readers a few remarks on the subject.

"The seeds of both the common and dwarf sunflower yield an oil little inferior to that of the olive for domestic purposes," says Lawson, so thus at the outset of our researches we come on a valuable asset for this plant. In Portugal, we find that the seeds are made into bread, as also into a kind of meal, and here in America they have been roasted and used as a substitute for coffee. The greatest objection to the cultivation of sunflowers is that they require very superior soil, and are a most impoverishing crop, particularly the taller growing sort (*Helianthus annuus*), from which circumstance the dwarf species (*Helianthus Indicus*) has been preferred by some cultivators, specially in France, who assert that as its dwarf habit of growth admits of a greater number of plants being grown on a given space, it is not so much inferior to the other in quantity of produce as, from its appearance, one would be led to expect. In addition to the uses above mentioned, some French authors assert that the leaves, either in a green or dried state, form excellent food for cows, and that they are greedily eaten by them. The stems also are valuable for fuel, and indeed are used for that purpose in some localities.

Sunflowers are best cultivated on hills, like field corn, but may also be used to fill up odd corners, and in time may attract more attention as a field crop than they do at present.

HARVESTING.

When the stem and discs of the sunflower become withered, and the seeds shining and dark colored, the plant is ready to be harvested. It may be simply pulled if weak, but out west here, those we have seen would better be attacked by an axe, as in tree felling, or a good, heavy, sharp, corn knife will answer the purpose. The discs are afterwards cut off with a sharp knife and the seeds rubbed out.

Lawson says that from 30 to 40 bushels of seed on 1 acre is a fair crop of sunflower. These will yield 50 gallons of oil, the refuse will make 1,500 pounds of oil cake, and the stalks burnt into ash will afford one half ton of potash. Professor Johnston mentions that the seed yields 15 per cent of oil.

COMPOSITION.

The analysis of sunflower seed and cake compared with flaxseed meal and cake is as follows:

	Water.	Albuminoids.	Fats.	Carb Hydr.	Ash.
Seed	80	130	210	77	30
Cake	100	342	110	170	106
Flaxseed meal	97	842	39	293	7
Flaxseed cake	117	283	90	200	77

In order that our readers may fully comprehend the value of the above analysis and form for themselves a comparison between the two seeds given, we shall explain the uses in feeding of the different component parts mentioned.

Water—Is absolutely necessary as a vehicle of plant-food and for carrying on the vital processes.

Albuminoids—Nitrogenous matters which go to form the flesh of animals, also gelatinoids and some of the fat, 100 parts of albuminoids yielding 51.4 of fat by combustion in the animal body these give heat and mechanical force, repair waste of nitrogenous tissue, and supply in themselves most of the requirements of the animal.

Fats—Go to form fat in the body, but many change into a different kind; they are burned in respiration to give heat and mechanical force, and thus are "fat formers" and "heat givers," one of fat equals 2.44 of starch in food value.

Carb-hydrates—Include starch, sugar, gum, dextrine, mucilage, etc., and are more immediately used for heat and mechanical work, but if taken in excess they are laid up as fat. They form the largest part of all vegetables.

Ash—The combustible or mineral part of plants or foods, consisting mostly of salts, and going to form bone, blood, etc., in the animal.

From the above it will be readily seen that sunflower seed and cake is quite a valuable feeding stuff, deserving of trial by all stockmen.

We shall welcome any experience which our readers can give regarding the cultivation, yield, or value as a feeding stuff.—*Farmer's Review.*

PEACH GROWING IN AMERICA.

We hear occasionally of a planter, who tired of the vicissitudes of coffee or tea planting takes orange growing in Florida or peach growing in Georgia. Some marvellous stories have been circulated about success in these departments. Let us see what Mr. Parnell, a brother of the Home Rule leader, says about peach growing—"In my early days," said Mr. Parnell to a correspondent who interviewed him, "I was advised that there were excellent chances for investment in the South, and especially in Georgia. It was my idea that thus located there was money in cotton, so I paid cash down 12,000 dollars for 1,500 acres. To this original purchase I have since added 500 acres, making my possession 2,000 acres in all. For three years I planted cotton only to find it a delusion." It was in this unfortunate moment that Mr. Parnell made up his mind that there was money in peaches. The great peach forest is described as containing acres and acres of ground, stretching indeed into miles, covered with every variety of tree. The trees, which number 150,000, are planted twelve feet apart, and are kept trimmed to the ground, so that a person standing can pick the rosy fruit from its fastness. When the first blush comes upon the cheek of the dainty beauties, 100 men, women and children are set to work, each armed with a flat basket, returning to the rendezvous when the bottom is covered. Thus they keep on day after day until the season is over. The story of Mr. Parnell's venture is briefly this—He invested 12,000 dollars in his plantation. He has spent over 5,000 dollars since in trees, seeds, and labour. Upon this investment he makes from 2,000 dollars to 10,000 dollars a year, and would not sell his peach forest for less than 300,000 dollars. Great as Charles Stewart Parnell is as the uncrowned king of Ireland, greater is John H. Parnell, the peach king of America. "I found it necessary to have recourse to English varieties. It was clear that a hard, firm peach which would bear handling would be a gold mine. In 1871 I brought from England 5,000 budded trees—the Beatrice, the Early Rivers, and the Early Louise. I have found that these three varieties meet every requirement. I have developed a hybrid, to which I have given the name of Parnell. The peach is destined to rank in the peach family as the Le Conte does among the peaches. I secured it from an accidental seedling. I made my first shipment of this peach five years ago, when it went off at 25 cents a bushel. I have now seven thousand trees of this variety. It has a dark red skin, white flesh, and is firm and hardy for shipment. The next is the Foster, a peach of yellow skin, saffron flesh, and firm mould. But one crop in three of this peach, however, is fit to ship. Of the Amelia peach, dark fleshed and brownish red cheek, I have over 8,000 trees. I have spent much time in experimenting, and believe that I have now solved all the difficulties of this neighbourhood. As old trees die I replace them, and also make a regular annual increase of 25,000 trees." "The worst enemy of the peach orchard," remarked Mr. Parnell, "is the half taught horticulturist with a pruning knife. There is no doubt but that peach trees understand the art of growing, and should be left alone. The borers will not do as much harm as the man who tries to exterminate them. If a tree yields bad fruit, just cut it down and plant. The principal danger, however, is winter killing, which is a misnomer because the killing takes place owing to the absence of winter. Where no winter comes the sap never sinks. A sudden cold day chills the tree, just as it does a man. I have fully exploded one idea prevalent, that it won't do to plant a new orchard upon the site of an old orchard. Thousands of my best trees are standing upon ground which has been the site of half-a-dozen previous orchards. Trees set out on the north-east never fail to have fruit. Peaches flourish in alternate years, sometimes one variety, and sometimes another. In 1875 there was a wonderful yield of early peaches. In 1878 the crop was equally good, but in 1879 there was a peach famine, which caught me two ways. The famine in Ireland deprived me of my rents, and the famine in peaches deprived me of my income here. In alternate years since, with wonderful regularity, the yield has upheld the theory. The earliest shipment ever made to New York was on the 16th of May, and the latest the 10th August, when the Delaware crop cuts off the Georgia sales. The demand for good fruit has never yet been met. I always have more orders than I can fill."—*Home and Colonial Mail.*

CINCHONA IN BOLIVIA.

The United States Minister at La Paz has something to say to his government relative to the cultivation of Cinchona in Bolivia. The scientific cultivation of quina in plantations has now been carried on for about seven years, and the districts in which it is chiefly practised are Mapiro, where 1,500,000 plants are cultivated; Louge, 500,000 plants; Yungas, 1,000,000; and Guany, 500,000; making a total of 6,500,000 plants. Where the principal quinas are, it is a very rough and broken country, the Andes being cut and swarmed into deep valleys in every direction. The trees are planted on the sides of the valleys or ridges, in altitudes of about 3,000 to 4,000 feet above the sea. They will grow higher up, even to 8,000 feet, but in that case they are stunted, and will give little or nothing of what is called quina bark. The plants require a great deal of sun, heavy rains, and fresh winds. A tree will yield from fifteen to twenty pounds of bark. The seed is collected in November and December, which in Bolivia are the early autumn months, and are planted very thickly in boxes or beds, about twelve feet in length and three feet in breadth, and placed on a slight declivity and well irrigated. When the plants

are about six inches in height, and have a few leaves, they are transplanted; holes of from eight to ten inches deep are dug about six feet apart, in which they are placed. The plants are then covered partly over with twigs and other light stuff, grass and leaves, to keep off the sun for about three months. When the plant is strong and healthy, the undergrowth of other plants is cleaned out, great care being taken in conducting this operation. This attention to the plants continues for about two years, and then they are left and considered sound. About 25 per cent of all the plants decay or rot before they come to maturity. When the tree is six years old, it is about fourteen feet in height, and has a diameter of about six inches up to six or seven feet. When the bark is of the most productive kind, the trunk grows straight and slender, and has the form of an orange tree. When a tree is left standing for ten or twelve years, it is over a foot in diameter, and the bark is thicker and heavier, but not so productive in quina. The bark is ready to cut when the tree is about six years old. A transverse incision is made in the trunk of the tree a few inches from the ground, another incision some twenty four inches higher up and two vertical incisions opposite. The bark is pulled off in two pieces. Two cuts and sometimes three are made in each tree twenty-two or twenty four inches long, and seven or eight inches wide. After the tree is stripped it is cut down, leaving a trunk about a foot above the ground, and from the base where the bark has been left there spring out about fifteen or twenty shoots or sprouts; these are left growing until they are a little higher than the stump, and are then thinned out, only two or three being left. The trees produce on an average about four or five pounds of bark, and the bark is placed in paved yards, and is generally cured in four days, but in rainy seasons it requires nearly three weeks. — *Home and Colonial Mail.*

AN ALARMING DISEASE AFFLICTING A NUMEROUS CLASS.

The disease commences with a slight derangement of the stomach, but if neglected, it in time involves the whole frame, embracing the kidneys, liver, pancreas, and in fact the entire glandular system; and the afflicted drags out a miserable existence until death gives relief from suffering. The disease is often mistaken for other complaints; but if the reader will ask himself the following questions, he will be able to determine whether he himself is one of the afflicted:—Have I distress, pain, or difficulty in breathing after eating? Is there a dull, heavy feeling, attended by drowsiness? Have the eyes a yellow tinge? Does thick sticky mucous gather about the gums and teeth in the mornings, accompanied by a disagreeable taste? Is the tongue coated? Are there pains in the sides and back? Is there a fullness about the right side as if the liver were enlarging? Is there constiveness? Is there vertigo or dizziness when rising suddenly from a horizontal position? Are the secretions from the kidneys scanty and highly coloured, with a deposit after standing? Does food ferment soon after eating, accompanied by flatulence or a belching of gas from the stomach? Is there frequent palpitation of the heart? These various symptoms may not be present at one time, but they torment the sufferer in turn as the dreadful disease progresses. If the case be one of long standing, there will be a dry, hacking cough, attended after a time by expectoration. In very advanced stages the skin assumes a dirty, brownish appearance, and the hands and feet are covered by a cold sticky perspiration. As the liver and kidneys become more and more diseased, rheumatic pains appear, and the usual treatment proves entirely unavailing against this latter agonising disorder. The origin of this malady is indigestion or dyspepsia, and a small quantity of the proper medicine will remove the disease if taken in its incipency. It is most important that the disease should be promptly and properly treated in its first stages, when a little medicine will effect a cure, and even when it has obtained a strong hold, the correct remedy should be persevered in until every vestige of the disease is eradicated, until the appetite has returned, and the digestive organs are restored to a healthy condition. The surest and most effectual remedy for this distressing complaint is "Seigel's Curative Syrup," a vegetable preparation, sold by all chemists and medicine vendors throughout the world, and by the proprietors, A. J. White, Limited, 17, Farringdon road, London, E.C. This Syrup strikes at the very foundation of the disease, and drives it, root and branch, out of the system.

Market Place, Pocklington, York, Oct. 2, 1882.

Sir,—Being a sufferer for years with dyspepsia in all its worst forms, and after spending pounds in medicines, I was at last persuaded to try Mother Seigel's Curative Syrup, and am thankful to say have derived more benefit from it than any other medicine I ever took, and would advise any one suffering from the same complaint to give it a trial, the results they would soon find out for themselves. If you like to make any use of this testimonial you are quite at liberty to do so.—Yours respectfully,

(Signed) R. TURNER.

Seigel's Operating Pills are the best family physic that has ever been discovered. They cleanse the bowels from all irritating substances, and leave them in a healthy condition. They cure constipation.

St. Mary street, Peterborough, Nov. 29, 1881.

Sir,—It gives me great pleasure to inform you of the benefit I have received from Seigel's Syrup. I have been troubled for years with dyspepsia, but after a few doses of the Syrup, I found relief, and after taking two bottles of it I feel quite cured.

I am, Sir, yours truly,

Mr. A. J. WHITE.

WILLIAM BRENT.

Horsingham, Whitehaven, Oct. 18, 1882.

Mr. A. J. WHITE.—Dear Sir,—I was for some time afflicted with piles, and was advised to give Mother Seigel's Syrup a trial

which I did. I am now happy to state that it has restored me to complete health.—I remain, yours respectfully,

(Signed) JOHN H. LUMSDEN.

August 15th, 1885.

Dear Sir,—I write to tell you that Mr. Henry Hillier of Farnborough, Wilts, informs me that he suffered from a severe form of indigestion for upwards of four years, and took no end of doctor's medicine without the slightest benefit, and declares that Seigel's Syrup which he got from me has saved his life.—Yours truly,

(Signed) N. WHITE.

Mr. WHITE.

Chemist, Calcutta.

September 25th, 1885.

Dear Sir,—I find the sale of Seigel's Syrup steadily increasing. All who have tried it speak very highly of its medicinal qualities. One customer describes it as a "Godsend to dyspeptic people." I always recommend it with confidence.—Faithfully yours,

(Signed) VINCENT A. WHITE.

Chemist-Dentist.

Murphy, Travell.

Proston, Sept. 21st, 1885.

My Dear Sir,—Your Syrup and Pills are still very popular with my customers, many saying they are the best family medicines possible.

The other day a customer came for two bottles of Syrup and said, "Mother Seigel" had saved the life of his wife, and he added, "one of these bottles I am sending fifteen miles away to a friend who is very ill. I have much faith in it."

The sale keeps up wonderfully; in fact, one would fancy almost that the people were beginning to breakfast, dine, and sup on Mother Seigel's Syrup, the demand is so constant and the satisfaction so great—I am, dear Sir, yours faithfully,

(Signed) W. BOWMAN.

To A. J. WHITE, Esq.

THE TROPICAL AGRICULTURIST:

A MONTHLY RECORD OF INFORMATION FOR PLANTERS OF Tea, Cacao, Cinchona, Coffee, India-rubber, Sugar, Palm, Cotton, Cardamoms, Kola, Cocoa, Quinacina, Nutmegs, Fibrous Plants, and other Products, suited for Cultivation in the Tropics.

[Published at Observer Office, Colombo, Ceylon, on or about the 1st of each Month. Commenced in June 1881.]

"THE TROPICAL AGRICULTURIST" has now an assured position in its large circulation in Ceylon, Southern and even Central and Northern India, the Straits Settlements, Sumatra, Java, Borneo, Northern Australia, Queensland, Central America, Natal, Mauritius, and the West Indies. From all sub-tropical planting settlements, we have had cordial approval of the publication, and an encouraging measure of support. The English, Indian, and Colonial Press have spoken in commendatory terms of the *T.A.*, as also directors of Public Gardens, from Sir Joseph Hooker, F.R.S., downwards, and so have all planters.

No planter should be without it.

Rates of subscription, including postage, in advance:

£1 Sterling.—Rupees 12.—5 Dollars.

Single copies, 6s. or Rs. 1; buck copies, 3s. or Rs. 1½.

Any one of the four volumes completed, bound in cloth, 1-stored, with comprehensive index, for £1 10s. (or Rs. 18), carriage prepaid. As a medium for English, American, and Australian ADVERTISEMENTS of goods suitable for the tropics, India, as well as Ceylon, the Straits Settlements, Java, and West Indies (Central America being included in that term), or connected with agriculture, the *Tropical Agriculturist* stands unrivalled, the work being constantly in the hands of Native as well as European and American agriculturists. Being a monthly Periodical, the *Tropical Agriculturist* lies on the table, and is very often referred to during each month, a fact which advertisers will know how to appreciate.

For the sale of plants, seeds, machinery, implements, &c., used in tropical (tea, sugar, fibres, &c.) agriculture, no better advertising medium exists.

Rates for Advertisements.

[9 words to line]

12 lines and under, per Line	0s. 9d. (3 annas).
Above twelve	0 8 (7 ")
Quarter Page, once	17s. Rs. 10
Half " "	41 8s. " 17
Whole " "	72 " 24

5 per cent off for each additional insertion.

For long contracts, special reductions.

Communications respecting advertisements and subscriptions for the *TROPICAL AGRICULTURIST* may be addressed to

Holloway's Ointment and Pills.—Diseases of the most formidable and chronic characters have been cured by Holloway's remedies. Ulcerations which have proved themselves incurable by other means have healed kindly, under the powerful and regenerating influence of this excellent Ointment. Scabs, most violent, excruciating eruptions, and glandular swellings can be most safely and effectually healed by Holloway's Ointment and Pills, which can do no harm under any circumstances. Neither of these medicines has anything deleterious in its composition; both are essentially purifying and strengthening in their nature. The combined power of these noble remedies enables them successfully to cope with most derangements of impurities, and to give, at once, relief, and permanent cure.

CALCUTTA:—SATURDAY, OCTOBER 17, 1885.

[No 42.

Health, Crop and Weather Report.

[FOR THE WEEK ENDING 7TH OCTOBER 1885]

Madras.—Partially withered dry crops in Bellary wonderfully revived, later sowings thriving, wet crops moderately good, communications interrupted by heavy rain. Standing crops fair small-pox in two taluks, cattle-disease in one of Kurnool. Rain much wanted in Tanjore. In Kistna, standing crops thriving; harvest *ambu* and *raji*, outturn below average. In Chingleput, standing crops generally good, but withering in parts. Fever abating, but anthrax in three taluks and small-pox in one. In Tanore, dry crops much improved by recent rains; fever and cattle-disease in parts, 13 deaths from cholera. In Coimbatore, standing crops generally good, but in Colegal much paddy has been lost, harvest paddy, *chola*, and *raji* in parts, outturn about average. General prospects fair, much improved in Bellary and Anantaporo.

Bombay.—Weather sultry. Fever in nine and cattle-disease in three taluks. In Kurrachee damage to crops in Tatta, Dadu, Mohwan, and John taluks, owing to drought, and in Ghorabari taluka to salt-water freshes late doing damage in Jati taluka. In Sholapoor, *harif* crops doing well, *raji* sowings commenced in lighter soils. A break in rain required. In Dhawar, more rain required in Bankaporo and Kalghatgi. Rice crops which were withering are reviving; *maru* and other crops good; cotton sowing in progress everywhere except in Navalgund and Gadag, where a break is required. In Kanara, rice crops thriving; harvest commenced on coast. In Rajkot, crops unhealthy in many parts, owing to want of rain. Good rain throughout the Deccan and Southern Mahratta Country and in parts of Gujerat. More still wanted in north of Gujerat, where the crops are withering. Sowing of *raji* crops in progress in several districts, standing crops injured by drought and rain in parts of Kurrachee, by storms in parts of Hyderabad, and by blight in parts of Rutnaur. Cholera and fever in parts of two, and cattle-disease in parts of eight districts.

Bangal.—In Chittagong, weather seasonable, standing crops in certain localities damaged by gales. In Dacca, prospects of crops good, harvesting of jute and *aus* nearly completed, early *aman* blossoming. In 24 Pargannahs, prospects of *aman*, except on low inundated lands, are good, harvesting of *aus* going on, estimated outturn 10 to 12 annas. Prices of common rice 10 annas, 10 chittacks to 15 seers per rupee. In Moorshedabad, weather seasonable. Prospects of *aman* in the earth excellent, *raji* being extensively sown and doing well, prospects generally much brighter. In Rangpore and Bhagulpore, prospects of winter rice good, *raji* and *aus* being sown, rice 12 seers per rupee. Cholera decreasing. In Purneah and other districts, crops doing well, and growing of cold weather crops progressing. Rain in almost all districts. Prospect of crops generally good except in the inundated tracts in the Buriman and Presidency Divisions and in Behar, and also on the Orissa coast, where stricken by cyclone *Bhadra* crops yielding fairly, where not damaged by floods. Price of rice getting easier in some districts. Public health generally good, though prevalence of fever and cholera is reported from some districts.

N.W. Provinces and Oudh.—Paddy being out; other crops doing well. A slight sprinkling of rain in places, more needed. General prospects, however, good. Cholera and fever somewhat abating, and so is cattle-disease; general health is good.

Punjab.—Slight rain in the Ferozepore and Rawul Pindie districts. Fever prevalent in the Hissar, Delhi, and Peshawar districts, and in the *Saluki* taluk of the Rawul Pindie districts. *Rabi* operations in progress in the south-east. Prices fluctuating. Health good in all districts.

Central Provinces.—There has been a timely fall of rain in Nimar, but more is required, especially in Raipore, where crops are reported to be withering. Prospects continue fair in all other districts. Prices steady.

British Burmah.—Cholera slight in five districts; fever slight in one district; elsewhere public health good; cattle-disease slight in eleven districts; elsewhere health of cattle good. Crop prospects good.

Assam.—Dark storm, slight cool. Reaping of *aus* and transplanting of *raji* crop finished. Common rice 14 seers 8 1/2 chittacks per rupee.

Mysore and Coorg.—Rain has fallen throughout the State. Standing crops improving, agricultural operations general. Horse gram being generally sown; irrigated *raji* and *maur* harvested in Tumkoor district. No material change in prices. Prospects of the season considerably improved by the recent rains. Public health good. Water supply and fodder available. Murrain reported in parts of Mysore, but generally cattle improving in condition.

Hyas and Hyderabad.—In Amraoti, crops progressing favourably; *raji* sowing commenced. In Akota, weather sultry. Crops in good condition except in Akota and Jalgaon taluks, where more rain is wanted. In Hyderabad, rain beneficial to standing crops, except in Shahabad taluk, where *harif* crops are slightly damaged. General health fair.

Central India States.—In Indore, prospects improved, and prices of food grain falling. Fever still in Morar and in Lakhkar. Cholera reported from several districts of Rawal state in Gooena, weather cloudy. In Sehore, prospects of crops unfavourable, rain much needed. In Nowroon, weather clear. Prices steady. Health generally good in all districts.

Rajpootana.—In all districts tanks fairly full; wells good. Health good. Crops being cut in Geroi, where weather very warm and dry for time of year. Rain wanted more or less, for the crops in Mierwana, Partabgarh, Meywar, Haroti, Jhalawar, Ajmere, Jeypore, Uwar and Bhaneer, crops in danger of being damaged for want of rain in Marwar.

Nipal.—Cold weather set in. Prospects good.

Letters to the Editor.

ORANGE CULTIVATION AND MANOE PESTS

TO THE EDITOR.

SIR,—I have read with great interest the letters of "T, An Old Malles" and Mr. Gurnumwry, which appeared in your issue of the 10th instant, on the above subjects; and I will feel obliged if you will permit me through your columns to say a few words also. I do not agree with *Old Malles* as to the soil recommended by him for general use for the orange, his process will not be productive of good results in every climate and soil; perhaps it might in his own garden, but it may have a different effect in a place where "T" desires to cultivate the orange. As to the very best method of raising orange trees, it is a fact that trees raised from seed, generally not more than ten per cent are good. The reason for this I believe is, that good seeds are not selected. Many seeds lose their vitality very early after being gathered. Most of our *malles* exercise no discretion in selecting and sowing seeds, and that is why you do not get a sufficient number of good plants. It is worth mentioning that budded trees are invariably two years later in producing their fruits than grafted ones. Budding is only resorted to by experienced horticulturists where a tree is rare. [We have never heard of this before.—Ed., J.A.]

In the 3rd para. of his letter *Old Malles* writes:—"Another point which I think worth mentioning is that I change my stock of fruit-bearing trees, after three years of full bearing. After 13 years' experience in the cultivation of the orange, I have found that when trees bear their full crop for three successive years, they begin to die off most unaccountably. I can assign no scientific reason for this." But your able correspondent makes up this deficiency by keeping a stock ready in the nursery, and planting out between the old trees from the time they first begin to fruit. This appears to me to be very true, but it can be rectified [by another method]—Dig up the surrounding ground of every tree in November and December after removing the fruits, and remove the old earth, and lay up in a high state for a couple of days or more (not longer than a week)

giving as much surface as possible, so that the atmosphere may act upon the soil, and then fill up the parts thus dug with a compost made of sandy loam from old pastures, 3 parts, and one part of pigeons' dung, then cover with some fresh earth, and water the trees regularly in the morning till the trees blossom. This will not only render the trees healthy, but will improve the soil and make the trees more fertile than before.

As to Mr. Guruswamy's questions, I would recommend him for the first to adopt the following method: loosen the soil round the roots and remove the old earth, clear the roots with a hard brush, then paint them with a solution of tobacco leaves 1 part, fresh lime 2 parts, and soap-suds 1 part, then cover the roots with earth composed of pigeons' dung, and water regularly, both in the morning and evening, till the trees begin to shoot out new leaves; or he may act according to the method suggested in my letter which appeared in your paper of the 9th May 1885. For the second, I would say that pigeons', rabbits', and hogs' dung, rotten cow-dung and slaughter-house offal and coal ashes (fresh) are very good fertilizers. For the last, I would refer him to my letter which appeared in your issue of the 1st August 1885. I would ask Mr. Guruswamy to try both your and my methods partly, and make known the result through your valuable paper.

HEM CHUNDRA DUTTA.

October 12, 1885.

Editorial Notes.

We understand that in August last the Mysore Gold Mining Company crushed 153 tons of ore, which yielded 366 ounces of gold.

Locusts, it appears, have made their appearance in a village of the Trichinopoly district, and are reported to be damaging the growing crops of sugarcane, ragi, and samba paddy. Arrangements have been made to watch and report their appearance and movements.

The collection of models of agricultural implements made by the Madras Government for the Colonial and Indian Exhibition is intended to remain permanently in London, and its cost is to be met from the balance at credit of agricultural services.

The opium returns of the first 6 months of the current financial year amounted to Rs. 4,34,400, being Rs. 24,81,400 better than the estimate. The receipts from Bengal opium were Rs. 2,58,606, below the estimate, while those from the opium duty on opium from Bombay were Rs. 26,10,321 above it.

The latest reports from the tea districts state that the weather in Assam and the north-eastern hills is to be unfavourable, and that the drought in the Terai that the autumn will be seriously affected. The weather in Cawnpore has been more favourable, and the drought is decreasing.

Reuter telegraph, under date 10th instant, that the Washington Agricultural Bureau's monthly report states that the average condition of the cotton crop in the 10 cotton States is 78 per cent. Reports received state that the crop is injured by excessive rain-storms and worms.

The total value of cotton exported from the several ports of British Burmah during the month of August 1885, amounted to Rs. 1,52,556, and weighed 6,917 cwt. The export was, however, confined to Rangoon alone.

The total value of imports of all articles during the same period amounted to Rs. 73,72,041. The imports of treasure (silver) were as follows:—

For Government	Rs. 80,000
„ private parties	8,72,946

There were no importations of gold. The total of exports of all articles for the same period amounted to Rs. 82,44,987, and of silver:—

By Government	Rs. 1,000
„ private parties	8,72,946

It will thus be seen that the imports were far in excess of the exports.

The London season of 1886 promises to prove a most attractive one. In addition to the Indian and Colonial Exhibition, which it is expected will be a gratifying success, there is to be "The American Exhibition of the Arts, Inventions, Manufactures, Products, and Resources of the United States." This Exhibition will open at Earl's Court, Kensington, London, on May 1, 1886; and one of its most instructive and interesting features, we are told, will be the "Industrial Hall," where all the most recently improved machinery will be exhibited in motion. Our American cousins have "gone ahead" of us in this direction, and the Exhibition ought to possess a peculiar interest for the British mechanic.

We understand that the indigo brokers estimate the total outturn of the present season at 110,000 maunds, a large falling off from the 166,507 maunds of last season. This is considerably below the original estimates. The falling off is confined chiefly to Behar and the North-West Provinces. In the former the outturn is expected to amount to only 52,850 maunds, against 62,038 maunds last year, while in the North-West Provinces this year's crop is estimated at under 40,000 maunds, against 84,300 maunds last year. The heavy rain that fell late in the season has tended largely to reduce the produce from the khouties in Behar, while the unfavourable season generally is said to have been the cause of the falling off in the North-West Provinces.

There has been some "hitch" as to the distribution of Mr. Mills' duties. The Government of Madras desire that the course of veterinary instruction at the Madras School of Agriculture should be so arranged as to set Mr. Mills free for the greater portion of the year, or for half the year, for the purpose of mofussil inspection. The Principal of the Agricultural College does not think it practicable, in the interests of the college, that the course of lectures could be so arranged unless the veterinary training is to be greatly restricted, and the curriculum laid down entirely re-arranged. He adds that the touring season would be, under ordinary circumstances, the working season of the college, and that, instead of curtailing veterinary instructions, it would appear to be the intention of the Government to extend and develop it very considerably in the college. In this opinion the Principal is supported by the Director of Public Instruction. The Government of Madras have, however, overruled this objection by observing that, although Mr. Mills is paid entirely from Agricultural Funds, three-fourths of his salary is at present spent in the service of the Agricultural Department. And that in these circumstances, it is reasonable to expect that some less dispropor- tionate division of his services should be agreed to by the latter department. The Government, therefore, insist on such a revision of the curriculum at the Agricultural School as will set Mr. Mills free for six months of the year for mofussil inspection. The difficulty of serving two masters is very clearly illustrated here.

The live-stock ordered on the Saldapet Farm are to be sold, and a certain number of them is to be retained for the use of the Agricultural School. The Acting Director of Agriculture, Mr. P. C. P. is submitting his proposals for the disposal of the live-stock and made a suggestion which, in our opinion, is deserving of favourable consideration. It is nothing more than the establishment of a stock-breeding farm. He says that Mr. W. Wilson, the late Director, had before he quitted his post, commenced instituting enquiries into the matter. The reason being the obvious necessity that existed for the introduction, throughout the presidency, of good breeding bulls; and it

want, it was expected, the farm would supply. Mr. Price says that complete information has not yet been obtained, but from what has thus far come to hand, it appears that there is but little doubt that a suitable spot can be found for experiment; and that, if the idea meets with the approbation of Government, it would, he suggests, be advisable to retain the cattle where they now are until a scheme can be worked out. They are reported mostly good beasts, which could not be replaced excepting at considerable cost. If Government do not approve of the plan, the cattle left on hand may be either sold or distributed gratis, whichever Government see fit. They have from first to last cost a good deal, and he therefore does not see why they should not be sold. The Board of Revenue strongly support the proposal for the retention of the cattle, pending preparation of a scheme for establishing a stock-breeding farm, which they regard as a great desideratum in the presidency, and the Government states that it will be glad to have the Director's promised scheme for a stock-breeding farm as early as possible.

**

The following is a summary of the health, crop, and weather reports for the week ending 7th October 1885:—

Good rain is again reported from the Madras presidency—in Bellary especially the fall was heavy; and both in that district and in Anantapore prospects have much improved. Elsewhere prospects are fair. From Mysore general rain is reported; the standing crops are improving, and agricultural operations are in general progress. Water and fodder are available. More rain is reported in parts of Mysore, but the cattle are generally improving in condition. In Coorg the season continues favourable. Good rain is reported throughout the Deccan and Southern Mahratta Country and in parts of Guzerat. In the north of Guzerat more rain is still needed for the crops, which are withering. Rabi sowings are going on in several districts. In the Berars the crops are in good condition, except in parts of Akola, where more rain is required. In the Nizam's Territories the recent rain has been beneficial to the crops. In the Central India and Rajpootana States little or no rain fell during the week under report. In Agra and Sehor in the former, and in Marwar, Kherwara, Maywar, Harowli, Jhallawar, and Ulwar in the latter, more rain is much wanted. In the Central Provinces prospects are fair in all districts, except in Nimar and Raipore, where the crops are suffering from want of rain. Preparations for the rabi are in progress in some districts. In the Punjab the rainfall of the week was confined to the Ferozepore and Rawalpindi districts, and more rain is wanted in places. Rabi operations are in progress in the south-east. In the North-Western Provinces and Oudh slight rain fell in a few districts, but more is required. General prospects are however good. General rain is reported from Bengal. Prospects of the crops are generally good, except on the inundated tracts in the Burdwan and Presidency division, and in Behar. On the Orissa coast crops have been much damaged by the late cyclone. The bhadoi crops are yielding fairly where not damaged by floods. In Assam agricultural prospects continue favourable. In British Burmah reasonable weather prevails, and crop prospects are good. The public health is generally fair. Prices are fluctuating in the North-Western Provinces and Oudh and in the Punjab;—in Mysore no material change is reported; while in Bengal the price of rice is falling in some districts. Elsewhere prices are generally steady.

**

A CORRESPONDENT of the *Bombay Gazette* says the Horse Show has been opened at Poona. It was very much inferior to its predecessors, and the exhibits were fewer in number and of worse quality than usual, while the yearlings are sadly deficient in those qualities which at one time were characteristic of the annual show in Poona. In the fancy classes the show was poor, very few hunters and teams competing. It was visited by a large number of visitors. His Excellency the Governor and staff were present and inspected the animals. The Commander-in-Chief distributed the prizes to the owners of the horses. No prizes were awarded to the exhibitors of horses four years and over or to geldings bred in India, but under clause X, a special prize of Rs. 50 was awarded to a horse called *Maulabau*, belonging to Mr. Dadabhai Hormadji Dubashi. Very few of the exhibited horses are being sold. Thus the Horse Show for 1885 closed.

The *Daily Chronicle* of the 7th September has the following paragraph:—"The singular feature in the jute trade was

reported. The ship *Falls of Dee*, which arrived in the Tay recently, had on board as part of her cargo 110 bales of jute gunny bags. This is said to be the first direct importation to Dundee of manufactured bags from Calcutta, and the fact that 80 tons of these goods have been sent from India to the head quarters of the jute industry in this country, is considered to be a proof of the keen competition now carried on in the jute trade. It is also reported that a Dundee jute merchant has exported, or is about to export, a quantity of jute to Calcutta, there being at present a scarcity of jute at the Indian port and a glut of it in Dundee, where the price of the article is much lower than it is at Calcutta, its original port."

**

MR. BRISS, the Commissioner of Salt and Abkari Revenue, has submitted his report regarding his enquiries into the measures adopted to secure the purity of monopoly salt, according to which there has been a slight improvement in some respects, but in others it has somewhat deteriorated. The Government of Madras, however, think that the quality has in recent years distinctly deteriorated—the average percentage of chloride of sodium, which in 1876 was 93.505, is now only 92.513. They cannot accept the Commissioner's excuse, of addition to the work of the officers of the Department as having anything to do with the deterioration in the quality of monopoly salt. But to aid the Commissioner in this work, it has been decided to place the services of Dr. Rutton at his disposal for six months to enquire and ascertain the cause of the deterioration in the quality of the salt.

**

We noticed a short time back the despatch of a consignment of mahogany seeds from Barbadoes, intended for Madras, but which had been sent all the way to England first, whence they were to be forwarded to Madras; and we remarked at the time that this circuitous mode of obtaining seeds was not calculated to result satisfactorily, as the vitality of the seeds was seriously affected by long keeping, and a double sea voyage. These seeds have now been received in Madras. The Secretary of State, in his forwarding letter, observes that they were ordered directly from Kew instead of through his office as usual. Mr. Lawson, the Director of Cinchona Plantations, Gardens and Parks, Nilgiris, in acknowledging receipt of the seeds says: "Inasmuch as many seeds lose their germinating power very rapidly, it is desirable that they should, in all cases, be imported direct, and not have to go through an intermediary office." This just bears out what we said, and we hope that some means will be found to import seeds from foreign countries for India direct, instead of their having to go all the way to the India Office, thence to the Royal Gardens at Kew, and from there forwarded to India. Red-tapeism might, we think, in the case of seeds, be dispensed with.

**

MR. WHYMPER, of the Nilgiri Brewery, offers a good field for the remunerative cultivation of barley in the southern presidency. Having been granted a contract from Government for the supply of malt liquors, the brewery will require large quantities of barley, which the proprietors would prefer to purchase locally, instead of having to import it from the Punjab. It appears that malt costs them Rs. 22-13-4 per quarter, delivered at Ottacumund, which is a very high rate, and they are prepared to buy at any price under Rs. 20 per quarter. Barley of an inferior quality is grown in the Nilgiris, but there is no reason why, when a demand has been created for good grain, a better quality cannot be grown in the Nilgiris. We are glad to learn that the Madras Government, to whom Mr. Whympere applied, are taking steps to make the requirements of the brewery as widely known as possible among the principal cultivators of the district. The Company would purchase about 40,000 bushels annually, which would be equal to about 23,000 maunds. The Madras Government, in passing orders upon the subject, observe that "there is no doubt that the barley at present grown by the Badagas has greatly deteriorated owing to the want of fresh seed, and there is no little doubt that, with this defect supplied, as good a quality of grain might be raised on the soil and in the climate of the Nilgiris as in any part of Asia or Europe. Having in view their large requirements, it is for the Company

to consider whether it would not be worth their while to import and distribute seed of good quality amongst the Badagas, who, it is thought, would gladly enter into contracts to supply the demand of the Brewery. If a certain market for the produce were once established, it is probable that cultivation would extend, and the requirements of the Brewery could be met at rates far more reasonable than under the present system of importation.

The value of fruit as a diet has often been insisted upon; but there seems to be a sort of prejudice to the use of fruit on a large scale, which may doubtless be traced to an ignorance of the laws of hygiene. The following remarks, which we extract from the *Journal of Health* will, we think, be read with interest. In a hot, enervating climate like that of India, fruit should form a very large proportion of our daily food:—

Of all the fruits with which we are blessed, the peach is the most delicious and digestible. There is nothing more palatable, wholesome, and medicinal than good ripe peaches. It is a mistaken idea that no fruit should be eaten at breakfast. It would be far better if our people would eat less bacon and grease at breakfast, and more fruits. In the morning there is an acid state of the secretions, and nothing is so well calculated to correct this as cooling, sub-acid fruits, such as peaches, apples, etc. The apple is one of the best of fruits. Baked or stewed apples will generally agree with the most delicate stomach, and are an excellent medicine in many cases. Green or half-ripe apples stewed and sweetened are pleasant to the taste, cooling, nourishing, laxative, far superior, in many cases, to the abominable doses of salts and oil usually given in fever and other diseases. Raw apples stewed are better for constipation than some pills. Oranges are very acceptable to most stomachs, having all the advantages of the acid alluded to, but the orange juice alone should be taken, rejecting the pulp. The same may be said of lemons, pomegranates and all that class. Lemonade is the best drink in fevers, and when thickened with sugar it is better than any of squills and other nauseants in many cases of cough. To matons act on the liver and bowels, and are much more pleasant and safe than blue mass. The juice should be used alone, rejecting the skins. The small seeded fruits, such as blackberries, figs, currants and strawberries, may be classed among the best foods and medicines. The sugar in them is nutritious, the acid is cooling and purifying and the seeds are laxative. We would be much the gainers if we would look more to our orchards and gardens for our medicines and less to drug stores. To cure fever or act on the kidneys, no febrifuge or diuretic is superior to water-melon, which may, with very few exceptions, be taken in sickness and in health in almost unlimited quantities, with positive benefit. But in using them, juice should be taken, excluding the pulp, and then the melon should be fresh and ripe.

It is true that we cannot procure apples in sufficient quantities, or at rates low enough to suit the pockets of the masses, but peaches, water-melons, oranges and figs are common enough, and should be largely used. We have other fruits, such as plantains, mangoes, plums, pappas, and pine-apples, custard apples, &c., which are all good, wholesome fruits, which ought to figure conspicuously on our tables. The tomato can be had nearly all the year round, and limes or lemons are plentiful in all seasons.

Mr. Rea, of the Archaeological Survey, has brought to notice an important archaeological discovery he has just made at a place called Narasapalayam, in the North Arcot district, which consists of some rock-cut excavations. He thinks that the hitherto received opinion that they are of Jain origin, and probably the ancient residence of monks, is erroneous; and that, judging from the architecture and inscriptions, are more important than had been supposed. He says they are similar in style to the caves at Mahabalipuram, which have been usually considered the most ancient works in Southern India; that the architecture and method of cutting the rock, likewise the letters employed in one of the inscriptions, are the same as the Pallava Grantha characters used at Mahabalipuram. He thinks that they date back somewhere to the 8th century. This is certainly an interesting "find," and we are glad to learn that the excavations have been completely surveyed, and that impressions of the inscriptions have been taken. Mr. Rea says that the impressions and translations of these inscriptions have

been despatched to Dr. Burgess, who will doubtless give us the benefit of his knowledge as to the value of this discovery in due course.

THE report submitted by Mr. Benson, Agricultural Reporter to the Government of Madras, on the working of the Madras Farm, shows that some good work was done there. The soil is said to be very poor and unsatisfactory, but much has been done to improve it. Suitable buildings for stock have been erected, and several large wells sunk, with good results as to water-supply. The present has been a bad season, and so was the last; but notwithstanding these drawbacks, guinea grass was put down on land partially reclaimed, which has done fairly well. Vegetables have also done well, while tobacco has been found to grow well, and some of that produced has been highly thought of. In fact, it presented characteristics which promise that the growth of leaf of good quality is possible. The cattle were all kept in boxes on the accumulated manures, with satisfactory results. It appears that the quantity of manure turned out on this system is very great, and the cost trifling. The cattle were generally doing well. Mr. Benson notices the want of land on which a supply of paddy straw could be raised for bedding. He thinks that certain land which Government declined to take up last year would answer this purpose very well, while it would at the same time present a fair site for carrying out experiments in the use of irrigation water, and the cropping of irrigation crops. This subject is under consideration. There is, apparently, no Superintendent appointed by Government over this farm. This is a want which should be supplied at once, as no good results can possibly be expected without a qualified superintendent. We understand that some men are available in the Agricultural College. Why should not one of these be appointed, instead of the Saidapet Farm overseer?

LAST week we reproduced a letter addressed by Mr. D. B. Allen to the *Englishman*, regarding the use of bones as manure, which has elicited the following from a correspondent, who signs himself "L. L.,"—and which will be read with interest:—

Mr. D. B. Allen, in your issue of the 6th instant, draws attention to the wholesale exportation of bones from the agricultural districts of India. It is a matter of congratulation to find that one so recently out in this country from the study of agriculture in England, has been struck with at least one of the evils which are undermining the productive powers of the soil in India. The evil against which Mr. Allen has raised his voice has been of longer continuity and of greater dimensions than even he seems to be aware of. I shall give here some figures taken from the Trade and Navigation returns published regularly by the Department of Finance and Commerce of the Government of India, which will show the weight and value of the bones exported during the last five years:—

	Tons.	Rs.
1880-81	7,490	2,15,821
1881-82	6,733	2,41,495
1882-83	10,993	4,19,131
1883-84	26,945	12,91,993
1884-85	18,883	7,87,179

These exports proceed from the different ports in the following proportions (to quote the figures of the last mentioned year):—

Ports in—	Tons.
Bengal	2,587
Bombay	9,862
Sind	2,287
Madras	3,048
British Borneo	190

And they are consigned chiefly to the United Kingdom, Ceylon, the Straits Settlements, and Hong-Kong. Besides bones, other soil-enriching substances are also exported, and their value amounts annually to over fifty thousand rupees. The export trade in bones has not escaped the attention of the officer (Mr. J. H. O'Connor) of the Department of Finance and Commerce, who has collected and reviews the statistics of the maritime trade of India. In 1884 he made the following remark:—"There was a large increase in the trade in animal bones, of which 23,000 tons were sent to England, though they might more usefully have been applied to the fertilization of Indian soil."

In the Review for 1884-85 also he notices the trade, and makes a similar remark. But it is evidently the duty of the Agricultural Departments of the different provinces to busy themselves in the matter, and to explain the evil to the various native and European associations interested in the welfare of the country and of agriculture in particular. Such associations, if made to understand the evil and to awaken to a sense of their duty, could easily induce land-owners to appreciate the value of bones, and either to prohibit their removal from their estates, or to levy such a rate for right of removal as to make the export an unprofitable enterprise.

That bones make a valuable manure has long been known, and their wholesale exportation from India is a matter for grave consideration. But "L. L.," who we think also hails from the Department of Finance and Commerce, has lost sight of the immense quantities of really valuable manure that are daily "wasted in the desert air" by the Municipality of Calcutta, and which might, with advantage, be more profitably utilized by the ryots and cultivators than bones, of the use of which the Indian cultivator knows little or nothing.

In December last year the Government of Bombay sanctioned a trial to be made for threshing wheat with a steam threshing machine. The experiment has come to an end, but with what success we are at present unable to say; as, although the Bombay Government have issued a Resolution on the subject, there is no mention made of the result of the experiment. Copies of the report submitted by the Director of Agriculture on the result of this trial, are to be forwarded "to all Commissioners, Collectors, and Political Officers attached to Native States, and the Chambers of Commerce at Bombay and Karachi for information"; but whether the *Indian Agriculturist* is to be favoured with a copy remains to be seen. The Resolution itself which we have cut out from a Bombay contemporary, and after omitting the preamble runs as follows:—

Messrs. Balmer, Lawrie & Co. should be thanked for the enterprise shown by them in sending the steam wheat thresher fully equipped and manned to this presidency for experimental purposes. The thanks of his Excellency the Governor in Council should also be conveyed to the Chief of Vinohur and Rao Sahib Mahadev Balkrishna, Mamlatdar of Nipha, for the energy and foresight displayed by them in facilitating and furthering the objects of the experiments.

The proposed payment of Rs. 1,250 to Messrs. Balmer, Lawrie & Co., as the Government share of the expenses incurred by them on account of the carriage and working of the machine, is sanctioned.

The Governor in Council is unable to entertain the proposal made by Mr. Ozaune that Government should buy the engine and thresher used last season at a maximum cost of Rs. 4,000 and work them in Khandesh in connection with the Bhadgaon Farm, as there is no budget grant for the purpose, and as it is not an object on which Government can ask the Government of India to sanction expenditure while the veto on all extraordinary outlay is sustained. In the circumstances the best course to adopt is to offer to Messrs. Balmer, Lawrie & Co. to bear half the expenses as proposed of another experiment in Gujarat next season; with the promise to buy one smaller complete machine for the Bhadgaon Farm hereafter, if the new experiment is fairly successful. The Director of Agriculture should be requested to ascertain if the Vinohurkar or some Chief in Kathiawar would buy the old machine.

The inference to be drawn from the foregoing is that the Government are too poor to purchase the steam thresher at a cost of Rs. 4,000, although it is required to be worked in Khandesh in connection with the Government Farm at Bhadgaon. The reason given for this would seem to be as 'poor' as the Government professes itself to be.

Messrs. Balmer, Lawrie and Co. are to be congratulated upon the spirit of enterprise displayed by them in connection with this experiment, and it is much to be regretted that they should receive so little encouragement at the hands of Government who profess themselves ready and willing to encourage private enterprise, especially in connection with the wheat trade of India.

In a country like India, abounding as it does in rich stores of archaeological and epigraphical interest, the recent Resolu-

tion of the Government of India to encourage a closer study of the subjects, cannot fail to be regarded as a move in the right direction. The question has occupied the attention of Government for some time past, but received a powerful impetus in 1883, when the Secretary of State for India, in sanctioning the appointment of Mr. Fleet as Epigraphist to the Government of India, suggested the desirability of training native scholars in such a way as to fit them hereafter for taking a prominent place in the prosecution of historical research. Mr. Fleet, whose opinion was obtained on this suggestion, advised that Professors of Sanskrit in Government Colleges should form classes of selected students for special training in epigraphical and historical researches. He observed that, with such a preliminary training, a few students would be secured who would be fitted to commence under him the more rigid study of critically examining new inscriptions, of translating and editing them, and of disposing of their contents in a scholar-like manner. The local Governments and Administrations committed on the subject were, however, of opinion that the adoption of Mr. Fleet's suggestion for the formation of such classes in Government Colleges would not be practicable; the reason given being that the time of the Professors was already fully occupied, and it was considered doubtful whether, under present circumstances, students would be forthcoming to attend them. But it was generally agreed that the several Universities might with advantage make Indian palaeography an optional subject for the higher degrees, and they are to consider what steps should be taken for attaining this object. We are therefore glad to find that, in order further to encourage the education and training of natives of India in epigraphy, the Governor-General in Council has suggested that a special prize of Rs. 500 should be offered by the local Government annually at each University to the student who does best in this subject if he is recommended for it by the examiners. It is also suggested that this prize might hereafter be supplemented by the liberality of private gentlemen interested in the ancient history of their country, if their attention were invited to the subject. In this respect the Viceroy has set an example by directing that an annual prize of Rs. 500 be offered for the best collection of inscriptions, with a critical essay on them by *bona fide* graduates of the Universities under 30 years of age. The essays are to be sent to the Epigraphist to the Government of India on or before the 1st April of each year, and the amount of the prize is to be charged in the contingent bill of the Epigraphist. The selected essay will be printed at the expense of Government. Lastly, in order to encourage the study of epigraphy among the Surveyors and Assistant Surveyors employed in the Archaeological Survey Department, the Governor-General in Council has sanctioned the grant of a reward of Rs. 500 to any *employee* of that department who qualifies in epigraphy within two years from the date of his appointment to the department.

THE question of cattle-disease is an important one in India, and too much care cannot be devoted to a clear and proper understanding of the subject. As a matter of fact, little or no attention is paid to the health of cattle, especially such as are intended for the slaughter-yard, and the meat of which adorns our tables later on in the form of tasty dishes cleverly and adroitly done up by the indispensable "baburchi." How much of the meat thus served up may be diseased, and unfit for food, it is difficult to say; but we should imagine, after reading the two articles on tuberculosis in the last number of the *North British Agriculturist*, that a very large percentage of the animals slaughtered for human consumption were affected with this terrible disease. Although, in the letter addressed by "J.H." to the *N.B.A.*, he takes a somewhat moderate view of the extent and effects of tuberculosis, yet he is willing to believe that Professor Walley has good and sufficient reasons for advising the slaughter and burial of all animals in whose system tuberculosis is evidenced by positive symptoms, with occupation to owners. The Professor even goes further, and maintains that even animals in whose system there is strong presumptive evidence of the existence of the disease should be so treated. The leading article in the *North British Agricult-*

tourist goes into the subject thoroughly, and puts the matter in plain language, and deals exhaustively with the disease in all its aspects. We have a shrewd suspicion that were a thorough system of investigation adopted in regard to the animals slaughtered in our large presidency towns and cantonment stations, some very startling discoveries would be made. One's blood runs cold to think that we may be taking into our system the germs of this horrible malady at every meal! It would, of course, be a morbid state of mind that would imagine a tubercle in every piece of beef or mutton; but the danger is none the less real for that. It behoves our municipal authorities to be exceptionally careful in passing animals for the slaughter-yard, and in minutely having examined the meat of all animals after being slaughtered. The two articles referred to by us will be found among our selections.

THE American Exhibition of arts, inventions, manufactures, and products, to be held in London next year, in juxtaposition to the Indian and Colonial Exhibition, promises to be quite a feature of the age. A correspondent of the *Statesman*, in a recent letter on the subject, says:—

A matter of gain to India will be the attention that Americans will be likely to give to the capabilities of private enterprise in India. In all that relates to agriculture, and not less in manufactures, there is a vast field offering, hitherto unattempted, and if our American friends will only show the more cautious Britisher the way, it is possible that the wealth of Ormus and of Ind may be found to exist not only in fable. The younger generation of the feudatory princes and noblemen have been educated under European auspices to an understanding of civilisation and enlightenment not comprehended by their fathers. Numbers of them will visit England this next year by special invitation of her Majesty's Government, and if their State coffers are drained of a large amount, the material gain to themselves and their people will be incalculable.

Further on, he gives the following interesting information:—

In the language of the Exhibition prospectus, it is proposed to arrange the entrance hall so that the European visitor shall take leave of his native soil, and shall temporarily be in and commence his visit to North America from the harbour of New York, with the Bartholdi Statue of Liberty, and the striking features of the Eastern entry to the United States around him. On leaving "New York Harbour," the visitor's first excursion will be through the various States across the Continent to San Francisco, from the Atlantic to the Pacific sea-boards. He will have the opportunity of inspecting collections, illustrating the wealth and civilisation of the entire country from east to west, from north to south. The railway routes and the picturesquely diversified scenery of the agricultural, pastoral, forest, and mining States will be illustrated by paintings, plans, and products. The natural resources and characteristic social conditions of the various parts of the vast territory extending from ocean to ocean, and from the lakes to the gulf of Mexico, will thus be exposed to view, and will offer exceptional facilities for comparison. The condition of the respective agricultural, grazing, mineral, and manufacturing localities will be particularly shown, and in a manner which will be intelligible and interesting to all; whilst the state of development and the undeveloped resources of the various sections will be brought under the visitor's notice in such a form as will enable him to establish a trustworthy basis for judgment as to their respective advantages. It is intended that this shall be one of the most valuable, instructive, and entertaining features of the Exhibition. The manufacturing department of the Exhibition will comprise the development in every branch of that inventive genius which in the United States has reached so high a point; and as far as possible, it is proposed to present the various processes in working order, by the aid of electricity, steam, gas, or hydraulic power. A separate hall (the Industrial Hall) will be devoted to the handicrafts pursued by white, Chinese, Indian, and negro men and girls. The labour-saving machinery, by which manual labour is reduced to a minimum, will be plentifully exhibited. The systems of working the great railways and canals, the oil wells, and the coal and silver mines will be shown, together with the machinery and organisation by which American manufactures are produced. Not only sight-seers, but manufacturers, land-owners, commercial men, farmers, all who are interested in stock-raising, and all who think of emigration, will find much to study in the Exhibition.

In addition to the above, and various forms of amusement and recreation to be provided, the following comprehensive programme is presented to the public:—

The Exhibition will include a Californian wine-shop, Florida fruit store; an Indian village; Indian canoe-makers and mat-weavers; ice drink pavilions and bars. Restaurants, with the products of the Eastern and Pacific coasts, of the Northern and the Southern States, characteristically prepared and served, by white and coloured male and female cooks and waiters, will help to mark the peculiarities and variety of American social development. Arrangements are being made to include a Dress Pavilion; an Atlantic Cable office; an Electrical Elevated Railway, and reproductions of the façades and interiors of comfortable hotels and public buildings. The lighting of the buildings and the illumination of the grounds, avenues, gardens and fountains by electricity, are already having the most careful attention of the council, and will in themselves constitute an especially interesting and attractive display. Finally, a feature of the Exhibition will be the manner in which the grounds will be laid out with a wealth of American flora; intersected with cool and shady avenues with seats everywhere, in sound of good music and the playing of fountains; and illuminated at night,—a fairy scene.

It is therefore, evident that the Americans know how to go about these matters. And when it is said that the entire Exhibition is a purely private undertaking, the United States Government providing no funds, we may well admire the indomitable enterprise of our trans-Atlantic cousins.

An interesting lecture was delivered by Colonel Hunt, C.B., Commissary-General, at Simla on the 2nd instant, on the subject of Stock farming in India. A full text of the lecture will be found among our selections. We quote below an important portion of the address, from which it will be evident that Colonel Hunt knows what he is talking about:—

From the cattle slaughtered for ration purposes the average outturn of ration meat is 143½ lbs. per head, and that of the sheep amounts to only 21½ lbs. These figures represent about one-fourth in each case of the average weight per carcass in England. Indeed, I may go further as regards mutton, and say that an English leg of mutton weighs often as much as the average whole sheep in India. As a rule the best of the slaughter stock comes into the hands of Government, so the average weight per carcass throughout the country must fall far below the figures I have named. This would not signify if the quality of the meat were good. But I am forced to confess that it is very indifferent. The orders on this subject are that the troops shall be supplied with the best pressed beef and mutton. But in a country where for half the year the grazing is of the most miserable description, and where no attempt is made to store and preserve for stall-feeding purposes the immense surplus of fodder produced during the other half of the year, and no attempt is also made at breeding and rearing for the purpose, it is clear that "bad must be the best of it." I have said that improvement in stock must follow improvement in fodder, but so bountiful is nature in the wonderful vegetation which starts every year with the fertilising monsoon, that I think I may qualify this opinion and say that, starting with that period and storing the natural growth of hay, it is feasible to any one possessing grazing land to start the improvement in both matters simultaneously.

In England it is not beneath the dignity of noblemen to purchase young stock every year and turn it into their park land, reselling it with great profit the next year, and in the interim going to but trifling expense in supplementing the grazing.

In India the conditions are different, and such results would by no means follow turning stock into grazing land, and allowing it to feed for itself. But if part of the land were set apart for hay making, and ensilage were resorted to in the early part of the monsoon, the system would be just as practicable and profitable in this country.—[The italics are ours.—ED., I. A.]

My personal experience as an Executive Commissioner Officer was that, during the dry season, of the cattle and sheep brought for sale, I used to have to reject a large proportion, and I have constantly had the dealers, who are not in this country system, offer to sell me the rejected animals at half price or even less. In the case of sheep I have frequently been obliged to reject entire droves, not finding any of them fit for my purpose, and in regard to both sheep and cattle, I have no hesitation in saying that any person possessing or renting a tract of good land, and obtaining twenty or thirty calves or ewes of our large Cantonments, could, by

purchasing stock during the dry months, allowing them to graze all over his ground for the first few weeks of the monsoon, and then reserving a certain portion of his land for grazing and collecting hay from the rest of it, laying out a small sum in the purchase of "horses," and cultivating a few fields of lucerne, carrots, &c., could start operations with the monsoon, and turn out his cattle and sheep in prime order after a few months, increasing their weight very much and giving us a vastly superior quality of beef and mutton. An enterprising person devoting his attention to this matter could, by selection from the ewes passing through his hands, start a small flock of sheep to be gradually increased, to breed from; I could give him good rams obtained by crossing with the best English and Australian sheep at the Hissar Farm, and I think I could guarantee that the wool alone would pay the expenses of the flock. I should also be very glad to contract with him to purchase his live stock by estimated weight for ration purposes, and he would commence to recoup his outlay within the first three or four months. His expenditure in farm buildings, cattle enclosures, &c., would be but small, if conducted on the principle which I am now introducing at the Hissar Farm, where we find our object best answered by using light thatches supported on a few poles; and enclosures made by cutting and collecting the "jowanna," or camel thorn (the dry leaves of which by the way shake in a heap on the ground afford an excellent description of hedges for sheep), and rolling it into hedges to form the enclosures.

EFFECTS OF SOIL AND CULTIVATION ON THE COLOUR OF WHEAT.

At the present time, when the question of improving and extending the cultivation of Indian wheat is attracting such a large share of attention, it is satisfactory to find that the Government of India is interesting itself to get together all the information possible on a very important subject in connection with wheat cultivation, *viz.*, as to whether the quality of the soil or the character of the cultivation effects a change in the colour of wheat. From the correspondence placed at our disposal by the Revenue and Agricultural Department of the Government of India, it appears that in June, 1884, enquiries were set on foot with a view to determining this point. Replies have been received from the several Local Governments, which tend in a measure to prove that soil and cultivation do change the colour of wheat.

Mr. Ozanne, the Director of Agriculture, Bombay, says that he has not instituted enquiries in this direction before, but he is arranging for a thorough and systematic test of the questions whether red wheat will turn to white, and *vice versa*, under the influences of soil and climate; and whether hard wheat will become soft, and soft hard, under similar conditions. He quotes two works on farm crops wherein it is stated that the colour of wheat is influenced in some measure by both soil and climate. The following paragraph, quoted by Mr. Ozanne from Wilson's *Our Farm Crops*, throws some light on the subject:—

"The difference in colour between the red and white varieties is probably mainly due to the nature and character of the soil in which they are grown. Fine white wheats gradually become darker and coarser when grown continuously on cold uncongenial soils, while the coarser red wheats grow, year after year, on rich warm soils in a good climate, generally lose their characteristics, become of a lighter red colour, then yellowish, and finally assume the external appearance of a strong white variety. It has been remarked that the grain in this respect is affected differently to the straw in changing its colour and character more quickly than that does. Hence we have many varieties of red wheats with white chaff and straw, and varieties of white wheats with red straw, the chaff and straw retaining their original colour after the influence of cultivation has effected a change in the grain."

He also quotes Dr. Forbes Watson, who thinks that the marked geographical distribution of the various wheats of India seems to show that the influences of climate on colour and hardness is considerable. As to the effects of excessive and late rainfalls, Mr. Ozanne says that he has sufficient evidence to prove that these tend to make hard wheat become more or less soft, and sometimes some cases where this actually happened.

The Director of Agriculture and Commerce, N.W. Provinces and Oudh, has reported that hand-picked white wheat was sent to certain district officers for experiment, one of whom has submitted a decisive report to the effect that five specimens were sown in the stiff clay of Muskara and Hamirpore, and that in every instance the produce was very much redder in colour than the parent seed. This is very conclusive proof that soil exercises great influence in changing the colour of wheat. Another instance is mentioned of a field of clayey soil close to the Cawnpore Agricultural Station being sown with hand-picked white wheat, the produce of which on being threshed was found to be inferior in appearance and colour to the original seed. The Director of Agriculture thinks that this effect is probably due to the presence of iron salts in which clayey soils are generally very rich. He observes, however, that the fact of white wheat in certain soils reverting to red in colour, is a matter of common knowledge in most districts; and that it is alluded to as an agricultural fact in Sir John Le Cantuer's book on *The Improvement of Wheat Seed by Observation and Selection*.

The report received from the Punjab is a little conflicting. It is stated that all the replies received from the various district officers consulted, do not throw much light on the subject; that the question appears to have been a new one to most farmers consulted by them; and that replies from many districts were to the effect that changes from white to red, or *vice versa*, were unknown. It is, however, stated that a good white wheat, if cultivated without care, and under conditions of soil, irrigation, &c., unsuitable to it, will by degrees degenerate into a red wheat; but that scarcely any instances were known of the improvement of a red wheat to a white by superior husbandry. It seems to us that the enquiries instituted in the Punjab on this subject were not of a nature to elicit satisfactory answers. It is apparent that no practical tests were applied to ascertain facts beyond doubt, as was the case in the N.W. Provinces and Oudh. The answers returned by the several district officers appear to be founded on hearsay evidence of native agriculturists, who cannot be expected to make accurate statements on a point requiring close observation, and experiment, and which entails some little trouble. But an impetus having recently been given to the wheat question in the Punjab by Sir Charles Nicholson, in his important resolution noticed in these columns a short time back, it will no doubt act as an incentive to more accurate enquiries into the subject under reference.

Equally unsatisfactory is the report of the Director of Agriculture, Central Provinces. He gives it as his opinion that he could discover no grounds whatever for believing that the colour and variety of wheat was altered by a change of soil or climate; and yet he says:—

The wheat grown in Chattisgarh mostly belongs to one of two well-marked varieties called respectively *hansa* and *kathia*. The former has a soft white grain resembling that of the *pusht* kind; the latter has a hard red grain. *Hansa* wheat is grown on deep black soil retentive of much moisture. *Kathia* wheat is grown on land in which yellow clay is mixed with black earth and which dries up comparatively soon. Their cultivation is, therefore, markedly localised. *Hansa* predominates along the western border of Chattisgarh where deep black soil abounds, and *kathia* is principally grown over the rest of the area where the soil is shallow.

It will be seen from the above that it is clearly the soil that affects the colour of the grain. Having got "mixed" so far, the Director makes another anomalous statement by observing that he "could find no grounds whatever for believing that the colour of real *kathia* could be changed to white, or the colour of white *hansa* to red, by growing either of them on land best suited to the other."

It appears to us to be evident that the Director took no practical steps to ascertain facts by actual experiments; and, therefore, his report must be regarded as being founded upon mere supposition and belief, instead of upon ascertained facts. He concludes thus:—

I should add, however, that I have had no opportunity of making enquiry respecting irrigated wheat, and it is, I believe, irrigation which is supposed in some places to effect a change of colour in wheat grain.

The supposition here referred to has no basis whatever, and we are constrained to remark that the report submitted by the Director is not what might have been expected from an officer of Mr. Fuller's standing and experience in agricultural matters.

It will be seen from what we have said that the only province where anything like a practical test was applied to ascertain whether soil and cultivation influence the colouring of wheat, was the N.-W. Provinces and Oudh; and these tests prove clearly that the influence is real. We may therefore accept it as an ascertained fact that soil and cultivation tend in a marked degree to change white wheat into red under certain conditions; but the question whether red wheat can be changed into white under similar conditions has yet to be proved; and it is, we presume, with a view to ascertaining this fact that the Government of India took up the enquiry. It is a pity, we think, that proper experiments should not have been conducted in this direction. Even the N.-W. Provinces and Oudh Government have omitted to ascertain whether red wheat can be changed into white by superior cultivation, and with different soil to that used in the experiments in the Hamirpore district.

Madras not being a wheat-growing country, we presume nothing was done there in this connection. Bengal, likewise, is not a wheat-growing country, cultivation being confined to certain limited areas, such as the Patna, Bhagulpore, and Shahabad districts. But the results of experiments, even in these districts, would have been none the less interesting. Mr. Finucane has doubtless instituted enquiries, the results of which will, we suppose, be made public in good time.

TANNEIF'S CASSIA.

NEARLY all plants yield tannin more or less, and the species that do so for economic purposes are innumerable. The mangrove, which fringes most tropical coast lines, has been turned to good account in this respect by the Chinese; and as regards India, we might mention that that variety of the *Cassia* known botanically as the *Auriculata*, a common shrub of Central and Southern India—more especially on the Coromandel coast—is extensively used for tanning purposes in those parts of the peninsula where it is indigenous. The southern parts of the Bellary district and all over the Mysore country, in the Madras presidency are the localities in which the plant grows wild, and where its collection forms an industrial occupation for a small section of the local population. The plant is bushy, and from four to eight feet high, in flower all the year round. The leaves, according to Roxburgh, are scattered, from eight to twelve paired, and the leaflets "oblong, entire, mucronate, a little downy." The flowers are "large, numerous, bright yellow," while the legumes are "linear, membranaceous, waved, from ten to twelve-nerved." The same authority states that the bark is "a pretty strong, simple astringent," while another declares it to be "one of the most valuable tanning substances of India." With this bark the natives commonly tan and dye their leather, and it is said to occupy in this country the same position that oak-bark does in Europe. The plant being quick-growing, is sufficiently large in a couple of years for cutting down, which operation does not necessarily imply destruction, but rather an increase of the number of shoots and a more prolific fresh growth. The method of operating of barking is very simple. The twigs are lopped off, cut into convenient lengths, and dried. The practice in the Mysore country and other parts of Southern India to effect the separation of the bark, is by "beating" with a mallet, on a wooden block, which readily loosens the outer rind or covering, the shells being afterwards bagged for the market. The price at Bangalore is from Rs. 60 to 70 per ton, rough bark; and better prices might be reasonably expected from the product if a little care and attention were bestowed upon its manufacture. The plant will grow anywhere, within its habitat; and, in its wild state, propagates fast. It is a feature in some of the treeless tracts of the Madras presidency, thriving in every variety of soil. The point, therefore, to be considered is—why this useful plant, so common and well-known, has not been utilised to a greater extent ere this?

Miscellaneous Items

THE Cawnpore market report for the past fortnight is a blank. Business is slack and depressed in almost every kind of country produce.

A KURNOOL correspondent writes on the 5th instant:—"We have had heavy rains in this district during the past week. There is no fear of famine now, and the crops are progressing favourably."

ARRANGEMENTS have been made to send from the Central Museum, Madras, for a couple of months in the cold season, a man accustomed to collect and preserve specimens of natural history, and the fruits of his labor will be sent to the Museum to be worked out and named.

A LUCKNOW paper says:—"Somewhat unexpectedly, although for the past day or two the weather has been gloomy, on Thursday a fair quantity of rain fell,—just such showers as are most likely to benefit agriculture. The heat has sensibly decreased as a direct result, and now we may look for an early advent of the cold season. The public health continues fairly satisfactory."

THE Poona Horse Show opened on Wednesday at 5 P.M., and remained open the next day, Thursday. There were fancy classes, the prizes in which depend entirely on public subscriptions, while in the *bond fide* breeders' classes no entrance fees were charged. There were twelve classes in the former and eleven in the latter, and a very large number of prizes were offered. H. H. the Commander-in-Chief was to distribute the prizes on the 8th.

IN Berar good seasonable showers of rain have fallen for the *kharif* crops. Cholera, in a mild form, is still prevalent in some districts. Although sufficient rain has fallen (41 inches) up to date in Nagpore, yet the quantity is 12 inches below the fall of last year for the same period. Timely showers of rain have fallen in the Ahmednagar district to save the crops. Last month's death was anticipated, but fortunately it has been averted. Secunderabad is also fortunate in getting 31 inches of rain to date.

A CORRESPONDENT of the *Ceylon Observer* writes:—"On Sunday, the 13th, at about 2.45 P.M., there was a drizzling of yellow rain spots at Kotahena: the spots were on the leaves, and persons who went out with white dresses at this time and who were caught in this rain found their clothes covered with yellow spots. This is a phenomenon not uncommon in Ceylon, and known as 'blood rain,' the colour of the drops being often red, owing to a fungus, or to dust in the upper atmosphere."

By instructions received from the Minister of Marine in Paris, the Newcastle coal in lumps housed in the temporary sheds on the north beach at Pondicherry is to be sold by public auction on the 30th instant. The quantity to be offered is 4,712 tons which will be put up in eight separate lots and the highest bidder will in each case be the purchaser. It would appear from this action of the French authorities that peace with China is considered permanent, at least for a year or two. The new sheds on the south beach are filled with patent fuel which the French navy engineers prefer to ordinary coal.

A CONTEMPORARY says:—"Some seven or eight years ago, a number of bees settled in the upper verandah of the Madras Bank, at Bangalore, and constructed two large hives, which hung to the eaves of the verandah. They were very peaceful, orderly neighbours for some time, but one unlucky day, they were accidentally disturbed in some manner, and wreaked their vengeance on every living thing that came in their way. The Bank doors had to be barricaded, as well as the Agent's private quarters, and the utmost confusion and consternation prevailed. A valuable horse belonging to a gentleman who called at the Bank was so fearfully stung, that it shortly after died. Other animals and several persons were more or less badly stung. The bees were after this, of course, dislodged, and not encouraged to settle at the Bank again. A few days ago, however, a large body of them put in an appearance at the Bank, and constructed no less than five hives in one time. Such dangerous neighbours, not being welcome from past experience, the interested colony was smoked out, advantage being taken of the fact of its being Sunday, and the Bank closed."

The recent heavy rains have, it is reported, done considerable damage to property in the Alor Patta of the Kolhapore district. The small stream at Mouza Mahasudi overflowed its banks, and the current carried away the house of a carpenter with all the property it contained. It appears that the carpenter, his wife, and two children were sleeping in a room in the house. In the middle of the night, he was roused by the heavy downpour which descended in torrents. On looking out he found that his house was surrounded by the flood. He therefore let loose his cattle and leaving his house to the mercy of the rains, found protection for himself, his wife, and children in another part of the village.

The Indian trade returns for the month of August, which have just been published, show a slight revival in the import trade, which had fallen off in July; coupled with a decrease in the value of Indian exports which, in July, had shown an increase. There was a large increase in the value of cotton piece-goods imported. In August, 1885, India imported less than two crores worth of cotton piece goods; whereas, for last August, the value exceeded 2½ crores. It may be noted that this increase is entirely due to large imports into Bengal and Burmah, the imports to Bombay, Sindh and Madras showing a considerable falling off. Turning to exports, we find a large decrease under the following heads:—rice, tea, raw cotton, seeds indigo, and other dye stuffs.

At the last sitting of the Abkari Commission Mr. P. M. Mehta, in resuming his address, dwelt upon the grievances of the bhundaris, who were suddenly thrown out of occupation owing to the tax on toddy trees being doubled at a bound. The bhundaris had taken such an extreme step because they knew that, with the excessive tree-tax that was demanded from them, they could only work at a heavy loss. It was a hardship to the bhundaris to be deprived of their only means of subsistence, and also a hardship to the poor that they should be deprived of a wholesome drink which was generally used by them as food. Mr. Maneckshaw J. Talyarkhan, who also addressed a few remarks to the Commission, urged that the tax should be considerably reduced and brought within reasonable limits, so that pure toddy could be had by the poor for two or three pice per bottle. The president, Mr. Grant, said the Commission would carefully consider the evidence, as well as the addresses to which they had listened, and then submit their report to Government.

The Mauritius Government recently, in acknowledging the receipt of a letter from the Madras Government, asking that working models or specimens of the 'Casse-tete' and 'Grattouse' used in Mauritius for the extraction of aloes fibre might, if possible, be despatched to Madras, have replied as follows:—"I beg to transmit to you the enclosed copies of the reports, from which you will see that the machines mentioned in Mr. de Chazal's pamphlet are the same that were used on the estates where the accidents alluded to in Mr. O'Connor's report occurred, and that they are considered inefficient. Some improvements have been made rendering their use safer, but they are still considered as machines requiring caution in their use. The feeding of these machines is reported to be dangerous, although a guard has been devised to prevent the operator's hand from coming into contact with the 'gratte' as it revolves. But this has not quite attained its object." The Government of Madras have decided that "in view of the existing imperfections pointed out in the letter read above in the various machines used for the experimental extraction of the aloes fibre, the Government of Mauritius will be informed that no specimens or models will at present be required by this Government."

Mr. ARTHUR P. SMITH, Assistant, Travancore Survey, writes to Madras Mail:—"I am credibly informed that some two years ago, it would seem, a Shanar ryot of the village of Kanchipuram, some miles from the postal village of Chinnamannur, in the Periyaculum Taluq of the Madras district, while sinking a well in his land, struck rock, which was blasted with gun-powder at the depth of 23 feet (or 19 metres). Immediately below this rock was found a supposed human skeleton of gigantic proportions. It strikes me as somewhat extraordinary that a human skeleton of such large proportions (however exaggerated, an eyewitness states it to be the remains of an ordinary man) was found beneath solid rock which required blasting. The bones rested on a bed of fine sand, and I believe are still to be found in the village. Perhaps the bones may belong to some ancient Shanar man, and this accounts for the largeness of size. I may here state that the village lies in an open and wild plain, where wild animals of any size could not have existed for

ages. I give the information for what it is worth, as it may be of interest to antiquarians and geologists. Unfortunately I have had no time to devote to the matter, and hope that some inquiry may be made regarding it. My informant was the native school-master of Comabay village, only four miles from the spot."

Selections.

MEETING OF THE INDIAN TEA ASSOCIATION.

A MEETING of the members of the Indian Tea Association was held at the rooms of the Bengal Chamber of Commerce on the 8th instant at 3 P.M., for the purpose of taking into consideration and adopting the new rules for the payment of bonus to coolies. Those were present—Mr. D Cruickshank (in the chair), Mr. Geo. Henderson, Mr. W. O. Bell-Irving, Mr. Jas Milne, Mr. G. M. Kelly, Mr. J. Horney, Mr. William Wilson, Mr. G. R. Watson, Mr. C. C. Macleod, Mr. J. C. E. Johnstone, Mr. W. Davidson, Mr. H. C. Garth, Mr. J. N. Stuart, and Mr. C. T. Richardson.

The Chairman opened the proceedings by saying that he thought it was to be regretted that Mr. Wilson, who had taken so much interest in this matter, should have been unable to attend and preside at the meeting. Fortunately, the bonus question had already been fully discussed, and he did not think there was very much to be said in connexion with these rules, which seemed to be generally approved of. It would be in the recollection of the members of the Association that at the general meeting, held in February last, certain revised bonus rules were approved of, and ordered to be submitted to the different local associations, and to members of the Association for an expression of opinion regarding them, in view of their confirmation and adoption at a later stage. These rules, the object of which was to reduce all round the rates of bonus paid to coolies, were considered desirable in view of the depressed state of the tea industry, and the necessity for making further reductions in expenditure. The rules had been circulated, and the association had received opinions regarding them from local bodies, and also from the home representatives of different companies. There was a considerable conflict of opinion in regard to the rules, the object of which, as stated, was a general reduction of bonus all round, and many were of opinion that they could not be carried out. Some said they could not risk the possible loss of labour by agreeing to them; others that if the rules were enforced, they would be obliged to withdraw from the Association as they could not see how they could be worked. In view of this conflict of opinion, the Committee came to the conclusion that it would be impossible to enforce rules compelling a general reduction of bonus, and they accordingly decided to modify their original proposals, and the revised rules, which had now been circulated for some weeks past, were drawn up. These are based on a different principle from those approved of at the General Meeting in February, and carried out the same principle that was embodied in the original bonus rules. That principle was that the Association would not attempt to interfere between an employer and his own labourers as regards the terms on which the latter might be re-engaged. The rules now in force were only intended to regulate the rates of bonus and the wages to be given to coolies leaving one garden of the Association to take employment in another belonging to it, an employer re-engaging his own labourers being free to make any terms he pleased with them. The same principle had been adhered to in the bonus rules which had now come up for consideration. It would be seen that in the original bonus rules, those which had been in operation for some time past, Rule 2 ran as follows:—

"That the maximum rates of bonus or advance to be given to coolies engaged by one garden from another belonging to the Association, shall be (except for gardens in whose favour owing to their situation and other circumstances, the General Committee may consider it desirable to relax the rule) Rs. 6 (per annum) for men, Rs. 4 (per annum) for women, and proportionate rates for children, without any increase of wages; or a corresponding increase in the monthly wages may be given in lieu of bonus or advance."

As regarded coolies re-engaged on gardens on which they had been employed heretofore, the Association had laid down no rule. A manager may make his own terms with the coolies he had imported, and who had been working under him. There had been a good deal of misunderstanding, he thought, with regard to those rules, as several correspondents had referred to them as if they understood them to apply to all coolies alike, and not alone to those engaged by one garden from another. For instance, the Planters' Stores Company write in a letter just received:—

"As I shall be unable to be present at the meeting called for to-day to consider the coolie bonus question, I beg to inform you that the undernoted gardens (Doom Dooma Tea Co., Ltd., Sandang Tea Co., Ltd., Wilton Tea Co., Ltd., Baitjan Tea Co., Ltd., Digby Tea Co., Ltd.) do not at present see their way to agree to stop giving the coolies the customary bonus, and are unanimous in their conviction that such a determination would tend to drive their labour, not merely from garden to garden, but from the district altogether, and we will consequently be unable to subscribe to any such resolution. They are, of course, willing to continue not to take labour from neighbouring gardens, and might, perhaps, see their way to gradually, and by a small amount at a time, reduce the rate of bonus; but even then the popularity of some of the gardens

would make it very difficult, if not impossible, to fix any equal and definite rate. Further than this, they are convinced it would be most hazardous and unwise to venture."

It appeared from this that the rules had been altogether misunderstood. The companies mentioned were willing to continue not to take labour from a neighbouring garden, and that was what the Association wanted. The rules were intended to discourage coolies going from one garden to another, leaving individual employers at liberty to make their own terms with their own coolies. He had not heard any grave objections to the rules as at present drafted. They would find that in the revised bonus rules, now under consideration, it is stated: "That no bonus or perquisite, such as rum, rice, blankets, &c., shall in future be given to coolies engaged by one garden from another belonging to the Association." That was to say, the object of the original rule was to reduce the rates of bonus from the higher rates, previously ruling, to an uniform rate of Rs. 5 to a man and Rs. 4 to a woman. The object of the present rules was to do away with bonuses altogether in the case of coolies engaged by one garden from another. But as many engagements were made under Act XIII, it was necessary to provide for advances to be given for agreements under that Act, in order to make them binding, and accordingly the rule went on to say: "In cases where agreements are made with such coolies under Act XIII of 1859, and it becomes necessary to make an advance in order to bring these agreements within the provisions of that Act, the amount of advance for a year's agreement shall not exceed Rs. 6 for a man and Rs. 4 for a woman, and shall be recovered by equal monthly instalments during the last six months of its currency." The principle of giving no bonus was here adhered to, the amount given under Act XIII as an advance being recovered during the last six months of the agreement. It would be seen, therefore, that the new rules went a step further than the original rules. The time allowed in which to receive opinions regarding the proposed rules was rather limited, but this was unavoidable as they wanted to get the rules adopted and passed during this month, in order that they might be in operation from November. So far as the answers he had seen went, no serious objection had been taken to the rules, and the discussion regarding them had already done much good, and had led to considerable reductions being made in the rates of bonus both in Assam and Cachar. He would be glad to hear what any gentleman had to say in reference to them, or any objections there might be to bring forward.

Mr. Stuart remarked that the only reply he had received from Assam showed that one of the managers of a garden there had misunderstood the rules in the same way as the Planters' Stores Company.

Mr. Henderson said that his firm had one objection to rule 5, and that was, that the time should be extended to six months instead of three as at present. In some districts twelve months were allowed.

The Chairman said that there was no reason why District Committees could not make it twelve months if they chose making it a local rule.

Mr. Henderson said that one or two men had written down, stating that they thought rule 4 invalid and quite useless.

The Chairman pointed out that under the Act a coolie was entitled to his discharge note.

Mr. Henderson was of opinion that coolies did not want it, and that the possession of one barred him from employment anywhere else.

Mr. Stuart enquired whether a manager under the Act was bound to give a discharge note.

The Chairman thought he was.

Mr. Richardson remarked that any coolie could go to a garden not in the Association, where he would be received with open arms.

Mr. Stuart said that the special object of rule 5 was to prevent coolies going from one garden to another.

The Chairman did not think the rule relating to discharge notes a very clear one, but the object of rule 5 was to discourage coolies changing from one garden to another.

Mr. Stuart thought it advisable to adjourn the meeting for the purpose of obtaining further opinions on the rules.

The Chairman said that he had received a telegram from the Secretary of the Cachar District Committee to the following effect:—

Meeting, Cachar Committee, 3rd October. Bonus Rules.—Rule 2. After last two lines thus "recovered during the currency of the agreement." Rule 3. Insert words "rate of" between monthly and wages. Rule 5 agreed to by 5 votes against 4.

He did think it would be a great pity to pass the rules without carrying with them all the local bodies. The original rule 5 was not so strict. At the meeting held in February last the rule (5) was submitted, and the Chairman said:—

"The next rule was a modification of the Jorhat proposal, and was as follows:—

"That no superintendent, manager, assistant manager, or other employed or agent of a garden represented in the Association shall, without the consent of the labourer's previous employer, employ or harbour any labourer from another garden also belonging to it, until a period of six months shall have elapsed from the time of the labourer leaving the garden on which he was last employed."

It seemed from the agreement of the Jorhat planters, which had been circulated, that it was almost the unanimous opinion that some such rule should be in force, but it had been considered better to modify the period of one year to six months."

The resolution was voted, and since then, owing to differences of opinion as regarded the rule, it has been further modified and limited to three months. A similar rule had been in operation for some time in several districts, he believed, being a local rule.

Mr. Henderson did not see how the Association gardens would suffer from the rules. They ought all to gain.

After some further conversation.

The Chairman remarked that it had been suggested that as they had received only one report from one local committee on the revised rules, and as the time had been very limited for obtaining the views of the various local committees, it would be desirable to adjourn the meeting for a month until reports came in from Assam and Sylhet. This view met with general approval, and the following resolution was put and carried unanimously:—

"That this Meeting be adjourned to the 12th November next, to admit of reports being received from those Local Committees who have not yet submitted their views regarding the proposed new bonus rules."

This resolution having been carried, the meeting separated after a vote of thanks to the chair.

STOCK FARMING IN INDIA.

The following is the text of the lecture delivered at Simla on Friday last, the 2nd instant, by Colonel J. Hunt, C.B., Commandary General, upon the above subject:—

The subject of my lecture is Stock Farming in India, as connected with hay and other fodder farming. My object in delivering this lecture is of a two-fold nature: 1st. The strictly professional motive of improving the economy and quality of the British Soldier's meat ration. 2nd. The advancement and prosperity of her Majesty's Indian Empire, in the improvement of the stock of sheep, cattle, and horses, &c., and in the consequent improvement in the trade in wool and hides, as well as in that of food supply. The subject is very closely connected with the agricultural interest of the country in regard to hay farming, a matter which, in proportion to the rapid extension of cultivation of food grains and of crops utilised in production of clothing, &c., is daily forcing itself upon the notice of the public and of Government with increased urgency; and in regard to which I must preface my discourse with some remarks to enable you to appreciate the force of the facts which I purpose laying before you. It is now some two or three years only since the difficulty in procuring forage for the mounted branches of the Service, and at the same time dealing fairly with the interests of the ryots and landholders in protecting their land from the ravages of the grass-cutter, has induced the Government to inaugurate a system of preserving Cantonment lands for production of hay, and of starting grass farms in the neighbourhood of large Cantonments where the fodder difficulty was particularly apparent. The officials employed on this duty have found it some what uphill work, and work of an unpopular nature, owing to the necessary uprooting of time-honoured customs and institutions which formed some of the items of the easy-going life so acceptable to the European constitution in the, to it, trying climate of India. But very material and important results have been attained, which may be summed up in the fact that it has been demonstrated that here, as in England, to utilise meadow land for hay-making instead of reserving it entirely for grazing, is a most profitable procedure; and that, so far from grazing land being injured by taking an annual crop of hay off it, it is improved; and while the prospects of the hay crop are by no means damaged by grazing off the first growth of grass which springs up with such rapidity when the monsoon sets in, there is good grazing also to be had from the after growth when the hay has been removed.

We have in our Indian Stud and other farming operations, long since realised the fact that grass land will not, as grazing land, support cattle throughout the year, and that to obtain the full value from such land resort must be had to hay-making; and we have also proved that excellent hay, which will retain its nourishing properties unimpaired for years, is obtainable from properly protected land all over the country. The value of the experiments carried out within the last two or three years consists largely in this knowledge having been disseminated through the country to our Cantonments, from whence it will spread rapidly to the zemindars and ryots; and when they realise that properly cured hay finds a ready market, and that it is the determination of Government to preserve to them their lands from trespass of any kind, and further that it is greatly to their interest to raise hay with the object of breeding superior cattle, sheep and horses, I have no doubt that the fodder difficulty will quickly become a thing of the past, and I confidently expect that in a very few years hay will be abundantly procurable, not only at every Cantonment in India, but in every halting place throughout the country. Officers like Sir H. Macpherson have done the State most valuable service in the interest displayed in this question of grass supply and their personal exertions to further it, but I do not go with them in their ideas of the necessity of ploughing and top-dressing to raise hay in India where the heavy rainfall of the monsoon of itself sufficiently loosens the soil and fertilises it. The gutta bunda system under which the Indian agriculturist divides his field into a number of small squares marked out by a slight elevation of the soil a few inches high, answers every purpose when the rainfall would not otherwise lay long enough to penetrate and loosen the soil. As for manuring and top-dressing it is quite needless. The concentrated rainfall which we have in the monsoon does this work by flooding the country, and depositing wherever nature or art has provided the means of retaining it, i.e., nature by depressions in the plains, or art by something in the gutta bunda line, ample manure, washed from places where the water cannot lie. Ploughing and top-dressing produce rank vegetation and render it too difficult to contend with weeds and injurious herbage. I am point to many places where good hay is collected from every monsoon from ground where the water is thus naturally detained for a while annually, and where never a head's turn has been done since creation in the way of ploughing, top-dressing or manuring. The Indian Kharab Officer will tell you how by the

simple process of fencing in ground for arboriculture, and in the interests of the growth of trees preventing the grass from being grazed down throughout the year, the hay crop has been increased whereas operations are carried on, seven fold.

The experience of the last year or two leads me to most strongly deprecate, not only ploughing and manuring, but cultivation of any thing but hay proper; and I think that the time has come to regulate the energy of certain of our enthusiasts whose ambition, not content with increasing the Cantonment income by the cultivation of various crops which they consider more profitable than hay, does not stop quite short of raising standing crops of Nankin suits of blue uniform on their parade grounds. I have, I think, dwelt sufficiently on hay culture to indicate how really stock farming is dependent upon it. I now, therefore, proceed with the subject of breeding and rearing cattle of all kinds, sheep, horses, and other beasts of burden. There can scarcely be any one present here to whom it is not apparent that vast improvement is possible in the breeds of horses, ponies, cattle, and sheep in this country. The country is a pastoral one; it affords splendid grazing in season, and is capable, without encroaching upon the growth of grain crops, of producing dry fodder in unlimited quantities to supplement grazing, and it is because its resources in fodder are undeveloped that the breeding of all kinds of domestic quadrupeds are so defective. The people, content with ploughs and agricultural implements of patterns with which Noah and his sons must have been familiar, in the matter of fodder rest satisfied with Bhooza, i.e., the straw of wheat, barley, and vetches, partly broken up in their rude process of threshing on the grain in lieu of threshing, and partly chopped up. They also store some supply of Kirby, i.e., the dry stocks of Indian corn, "Jowar," Bajra, &c., and in certain districts, like Gwalior, dry grass, I cannot call it hay, is stored for plough cattle and horses. The storing of this dry grass is entirely subservient to crop growing, and as the hay ought to be cut and cured in September when their ploughing operations commence, they will not accord it the necessary attention and labour; hence it is allowed to stand for months until the sap has receded from it, and it is of little or no value when it is collected. The value of properly cured hay may be estimated from the following:—13 lb. of green grass are the equivalent of 1 lb. of dry grass. The regulation ration of army horses is 30 lb. green grass or 20 lb. hay, but this hay is the ordinary dry grass procured in Indian markets. Of properly cured hay 10 to 12 lb. is given by the Livery-stable keepers in Calcutta, and is found an ample quantity. There would thus be a saving of about 18 to 20 lb. substituting properly cured hay for the green grass ration of Army horses, and of 8 to 10 lb. by substituting it for the present hay ration of those horses. The quantity stored of this description of fodder, which in itself is very deficient of nourishment, and is only fit for humped cattle and sheep, is scarcely equal to the requirements of plough cattle and draught bullocks, in regard to which and to horses, for whom short grass is sown from the surface of the land, I may say that all efforts amongst the natives is confined; and it is to this absence of all attempt at cultivating and setting land apart for the growth of fodder that the failure of our stock-breeding operations in India, the natives to practice the systematic breeding of stock, is attributable. We have to get first to get them to interest themselves in fodder cultivation, and then the stock breeding will follow, and the combined measure will result in a considerable increase in the wealth and prosperity of the country. The great difficulty in inducing the natives of India to cultivate fodder, that, while such is the prevalent belief, and even whether it be the best or not, and if it be not good money to be given the quality. In the United Kingdom, cultivation of fodder is a necessity, the proportion of cattle cultivated land being 29 out of 100 acres, the average in India being only 10.5, while the proportion of woodland in India is 10 out of 100, and in the United Kingdom is 20 out of 100. As regards my primary object in writing to you, viz., the improvement of the breed of the King of the Hill, I will now place before you some statistical information which will perhaps facilitate your work. In the above table, the returns show the total consumption of cattle and sheep in the supply of railways, which is to be as follows:—

		Cattle.	Sheep.	Total.
Bengal	Cattle	3,177	60,199	63,376
	Sheep	78,169	16,677	94,846
Bombay	Cattle	1,134	21,457	22,591
	Sheep	66,695	14,280	80,975
Madras	Cattle	1,022	18,128	19,150
	Sheep	59,935	13,187	73,122

Total Head of Cattle .. 1,06,151

Total Head of Sheep .. 2,48,738

Of the cattle 101,362 were cows and only 5,322 males; and of sheep 204,709 were males and 44,044 ewes. The proportion of female to male cattle slaughtered is of a most startling character. It indicates, in my opinion, that while the supply of cattle is as yet very plentiful, in as much as that the necessity for reservation of a large proportion of females for breed purposes has not been forced upon the attention of the breeders, a very destructive system of slaughtering cows exists, which must in the long run materially affect the market. As regards sheep the proportion of ewes to males slaughtered, 44,044 of the former against 204,709 of the latter, is remarkable, and is due to restrictions having in 1873 been placed by Government on the number of ewes to be slaughtered by the Commissioned Department. This was occasioned by alarm being felt even then that the supply of wool should result from the indiscriminate slaughter of male and female sheep. The measure can, however, have had scarcely any effect, the number of sheep killed for troops being quite insignificant compared with that of the number consumed by the population, and it is my opinion that the score of

1873 was by no means groundless, and that since then the supply of sheep has diminished.

The export of hides amounts to 8,605,796³ annually, which, set against the number of animals slaughtered for the use of the troops, shows that the consumption for this purpose is a mere drop in the ocean, the more so when it is remembered that the expenditure of hides in India for all the different purposes for which leather is used is also enormous.

	Hides.	
Calcutta	6,938,934	
Bombay	6,75,000	
Madras	1,041,960	
	8,605,794	
	Sheep Skins.	
Calcutta	222,987	
Bombay	2,856,000	
Madras	3,865,720	
	6,944,707	

From the cattle slaughtered for ration purposes the average outturn of ration meat is 14½ lbs. per head, and that of the sheep amounts to only 2½ lbs. These figures represent about one-fourth in each case of the average weight per carcass in England. Indeed I may go further as regards mutton, and say that an English log of mutton weighs often as much as the average whole sheep in India. As a rule the best of the slaughter stock comes into the hands of Government, so the average weight per carcass throughout the country must fall far below the figures I have named. This would not signify if the quality of the meat were good. But I am forced to confess that it is very indifferent. The orders on the subject are that the troops shall be supplied with the best grass fed beef and mutton. But in a country where for half the year the grazing is of the most miserable description, and where no attempt is made to store and preserve for stock feeding purposes the immense surplus of fodder produced during the other half of the year, and no attempt is also made at breeding and rearing for the purpose, it is clear that "bad" must be the best of it. I have said that improvement in stock must follow improvement in fodder, but so beneficial is nature in the wonderful vegetation which starts every year with the fertilising monsoon, that I think I may qualify this opinion, and say that, starting with that period, and storing the natural growth of hay, it is feasible to any one possessing grazing land to start the improvement in both matters simultaneously.

In England it is not beneath the dignity of noblemen to purchase young stock every year and turn it into their parks, reselling it with great profit the next year, and in the interval going to but trifling expense in supplementing the grazing.

In India the conditions are different, and such results would, by no means, follow turning stock into grazing land, and allowing it to find for itself. But if part of the land were set apart for hay-making, and ensilage were resorted to in the early part of the monsoon, the system would be just as practicable and profitable in this country.

My personal experience as an Executive Commissariat Officer was that, during the dry season, of the cattle and sheep brought for sale, I used to have to reject a large proportion, and I have occasionally and the dealers, who are not in this country graziers, offer to return the rejected animals at half price or even less. In the case of sheep I have frequently been obliged to reject entire droves, not finding any of them fit for my purpose, and in regard to both sheep and cattle, I have no hesitation in saying that any person purchasing or renting a tract of grass land within twenty or thirty miles of any of our large cantonments, could, by purchasing stock during the dry months, allowing them to graze all over his ground for the first few weeks of the monsoon, and then reserving a certain number or his land for grazing and collecting hay from the rest of it, laying on a small sum in the purchase of kirbee, and cultivating a few inches of turnips, carrots, &c., could start operations with the monsoon, and turn out his cattle and sheep in prime order after a few months, increasing their weight very much, and giving on a costly enterprise a return to this matter could by selection from the ewes passing through his hands, start a small flock of sheep to be gradually increased, to breed from; I could give him good rams obtained by crossing with the best English and Australian sheep at the Hissar Farm, and I think I could guarantee that the wool alone would pay the expenses of the flock. I should also be very glad to contract with him to purchase his live stock by estimated weight for ration purposes, and he would commence to recoup his outlay within the first three or four months. His expenditure in farm buildings, cattle enclosures, &c., would be but small, if conducted on the principle which I am now introducing at the Hissar Farm, where we find our object best answered by using light thatches supported on a few poles; and enclosures made by cutting and collecting the "jowassa," or camel thorn, the dry leaves of which by the way shaken in a heap on the ground, afford an excellent description of bhooza for sheep; and cutting it into hedges to form the enclosures. I trust that, by my journeying through the country this winter, I may find some of our Muhammadan gentlemen of means who would be willing to embark in such a speculation as this, and I am sure that in such cases Government would be willing to assist, as far as circumstances admit, by granting them tracts of grass land. As regards the Hindu section of the community, whose religious prejudices would prevent their having anything to do with slaughter stock, an ample field is open to them in the setting apart of grass land for breeding horses, mules, plough cattle and sheep, the latter for wool; and

If our District Officers and Political Agents, will interest themselves personally in the matter, grazing and fodder farms will quickly spring up in different parts of the country. I have alluded frequently to the Government Cattle Farm at Hissar, regarding which I will now put before you some details, as, the farm, until within the last year or two, affords a very notable instance of the mistake of placing too great reliance on grazing to the neglect of the necessary storage fodder to supplement the same. The principle formerly observed at the place having been to store but a very limited quantity of hay, under the idea that to take more off the farm land would interfere with grazing.

(To be continued.)

TUBERCULOSIS.

WHAT is tuberculosis? That, we feel sure, has been a common question among readers of the *North British Agriculturist* during the last two weeks. We propose to answer it, and in doing so, we shall not content ourselves with a bare explanation of what is the diseased condition to which the term is applied, but we will attempt to give in plain language such an account of the malady as may enable nonprofessional readers to follow intelligently the important discussions that from time to time are raised concerning it.

Tuberculosis is the name applied to a disease in which there are developed, in various parts of the body, little growths, or tubercles, having a characteristic microscopic structure. It attacks both men and animals, and is known by a variety of names. Thus in the human subject it is this condition that is at the root of the ordinary form of what is termed Consumption, Wasting, or Phthisis; while in the lower animals, it is variously known as Pining, Consumption, Grapes, Kernels, Cysts, Angioberries, &c.

The growths from which the technical name of the affection is derived have a very variable distribution. In cattle their most common seat is the lungs and pleura (the lining membrane of the chest), while next in order of frequency comes the peritoneum (the lining membrane of the belly). In other cases the tubercles grow in the reproductive organs of either sex, in the spleen, the liver, the intestines, the kidneys, the udder, the brain, lymphatic glands, joints, muscles, &c. In most cases the new growths do not invade more than two or three of these situations, but in some instances there is a rapid development of the tubercles throughout the animal's system, and to this latter condition the term *acute or general tuberculosis* is applied.

The individual tubercles are of small size—smaller than a pin's head, but by coalescence they produce large masses of new tissue in the organs where they appear. Thus, in the lungs, the normal spongy structure becomes destroyed, and its place taken by solid masses, which, later on, tend to soften, break down, and be coughed up. On the pleura and peritoneum the aggregations of tubercles form large projecting masses, resembling a cauliflower or a bunch of grapes, and it is from these that many of the common names for the disease are derived. In the early stage the tubercles are of a greyish white colour, but when more mature they become yellow. When they attain a certain size, they tend to assume a consistence like cheese, and this may either soften and break down, or it may partially dry up, and become gritty from a deposit of lime salts in it.

Among the lower animals cattle are most frequently the subjects of tuberculosis, and after these come pigs. Goats are occasionally attacked by it, but it is doubtful whether horses, sheep, or dogs ever contract the disease spontaneously. Within recent years, however, it has been shown to attack fowls, and it at times proves a great scourge in the poultry yard.

From the various situations in which the lesions of tuberculosis appear, it will readily be understood that its symptoms are not well defined. When it attacks the lungs and pleura (which, as already stated, are its most common site), the animal suffers from a cough, evinces pain on pressure between the ribs, and steadily emaciates, until, if the disease is allowed to run its course, the animal is reduced to the condition of a living skeleton. If less vital parts are the seat of the new growth, the symptoms may be very obscure. It is almost an everyday occurrence for animals to be slaughtered whose carcasses present on the peritoneum and pleura most extensive growths of tubercles, such animals never having evinced in the minds of their owners a suspicion of the serious affection of which they were the subjects. It is a point that cannot be too strongly emphasised, that an animal may have an extensive growth of tubercle in its system, and give no other evidence of it than a certain unthriftiness, and a lack of tendency to fatten, no matter how favourably circumstanced. Among cows a not infrequent seat of tubercle is some part of the generative system, such as the ovaries of the womb. The diseased process is here a common cause of sterility, and it at the same time creates a condition of sexual excitement which makes the cow almost constantly 'bulling.'

When the disease invades the udder, it produces a diffuse swelling in which there is little or no pain. The swelling generally affects only one quarter of the udder, and for a considerable time, at least, the milk from the diseased portion may present to the naked eye no abnormal characters. The importance of the last mentioned point will be shown later on.

Tuberculosis is by no means a new disease. It has even been surmised that it was known in the time of Moses, and certain it is that it is referred to by some of the ancient writers in terms that leave no doubt as to its identity. Nevertheless, it is only within very recent years that a satisfactory account of its pathology has been given. The two important points that have for a long time been under discussion, and to which until recently no direct answer could be given, are—1st. Is tuberculosis an infectious (or

contagious) malady? and 2nd. Is tuberculosis of animals identical with the like named disease in man?

Clinical observation had long ago led many eminent medical men to the belief that the disease was at times transmitted from a diseased individual to the healthy, the most common medium of infection being the material coughed up and expectorated from a diseased lung; though in some instances the inhalation of the same atmosphere with an affected person, or even the wearing of the clothes of one dead of the disease, was reckoned upon as a sufficient cause. Similarly, some veterinarians had been led to the conclusion that the introduction of a tuberculous cow was a great danger to the herd—in fact, that the disease spread by infection or contagion. Still, until very recently, these views did not meet with anything like wide acceptance, and perhaps the most general view of the nature of the disease was, that in certain individuals an inflammation of, say the lungs, or a lymphatic gland, excited by an ordinary cause (such as cold, &c.) was prone to be followed by a softening and breaking up at the seat of inflammation, and that the softened materials, when carried by the vessels to other organs, were capable of acting as an irritant, and setting up a growth of tubercles. It was not, however, generally believed that there was any similarity as regards contagiousness between tuberculosis and glanders or pleuro-pneumonia.

But if clinical observation had failed to afford convincing proof of the contagious character of tuberculosis, the same can hardly be said of the results of experiment. Gerlach attempted to settle the question by feeding animals either with tuberculous matter, or with flesh taken from animals having distinct tubercular growth in some part of the body. In this way he succeeded in producing the disease in 35 out of 46 animals when he fed them on uncooked tubercular matter and in 10 out of 15 with the same matter cooked. Of other 35 animals that he fed with uncooked flesh from tubercular cows, 8 became the subjects of tuberculosis. Other investigators tested the effect of tubercular matter when inoculated into the system of healthy animals. Thus, Baumgarten succeeded in producing tuberculosis in rabbits by inoculating them in the eye with blood taken from another rabbit affected with the disease. Toussaint also experimented in the same way, using as the inoculating material tubercular matter from the lungs, saliva, mucus from the nose, and urine, of tuberculous animals. All of these materials he found capable of setting up tuberculosis in such animals as pigs, rabbits, and cows. A third set of experimenters tried the effect of feeding animals with the milk of tuberculous cows. Johns, for example, fed two pigs and one rabbit with milk from a tuberculous cow, using the milk taken from an apparently healthy quarter of the udder. These animals were fed with this milk for about one month, and were killed after an interval of about six months. All the three animals were found on post-mortem examination to be extensively affected with tuberculosis. In another case he fed 3 pigs and 2 rabbits with milk, part of which was taken from a quarter of the udder affected with tuberculosis. These animals were fed with the milk for about five weeks, and were killed after an interval of two months. After death both pigs and rabbits showed in various parts of their bodies extensive growths of tubercle.

Many similar experiments might be cited, all having the same result; and in view of the evidence that they afford, and of the evidence in the same direction afforded by clinical observation, it is impossible to arrive at any other conclusion than that tuberculosis is a contagious malady.—*North British Agriculturist*.

TUBERCULOSIS IN CATTLE.

SIR,—I feel glad that so able an authority as Professor Walley writes publicly on this matter. He asks, 'what I mean by a wholesale slaughtering and burial of the carcasses of phthisical cattle?' and he answers the question himself in the next paragraph when he says, 'I have advised, and do so still the slaughter of all animals in whose system tuberculosis is evidenced by positive symptoms; not only so, but I have gone further, and advised that animals in whose system there is strong presumptive evidence of the existence of the disease, but with compensation to the owners.' May I presume that the carcasses of all these animals that were slaughtered, showing phthisical tubercles or apical lesions were destroyed, and that these are the suppressive measures that are demanded? Whether rightly or wrongly, this is certainly an innovation from the general rule. Professor Walley goes on to say, 'Does "J. H." know what he is writing about?' Certainly not properly, as I am very anxious to know a great deal more; but I am happy to say, for the sake of frail and suffering humanity, that I am not prepared to accept of the terrible conclusion he has arrived at, when he says, 'Once for all, let us be distinctly understood that tuberculosis is absolutely incurable.' The progressive nature of science is a wonderful power, and the recuperative power of nature is by far more marvellous still, being nothing less than the veiled power of the Divine Father. Therefore, I cannot agree with Professor Walley, when he says that the system cannot wholly recover its strength again. I think I have known cases where the morbid deposit had become liquidified and absorbed and thrown off by the invigorated system. Furthermore, cannot Professor Walley see as nothing like a line of demarcation in his admission of the disease being capable of being cured in its progress by the active and affecting media becoming potent? I think this, in veterinary practice, is quite a common occurrence, and the animals fed up and sent to the slaughter. Does he imagine that flesh from such a source, when not containing an active virulent virus, would cause phthisis in a highly susceptible human subject? For my part, I think that would be ascribing the matter ridiculously low, as if such could be the case, we surely should have little difficulty about the supposition that even a single individual, even without eating such flesh, could not escape the

influence of the almost universal germ. It would be interesting to know how far vegetarians are exempt from consumption in comparison with flesh-eaters. Butchers could tell a curious tale of how many meningitis, tuberculous, and other deposits they find in and on animals slaughtered for human food. So that if every case were to prove deleterious, I should consider few people, in the large cities at least, could escape the malady. I must confess that I do not think this matter has been sufficiently investigated yet, and that there are some kinds of tubercle that must give something like negative result; and I know of no argument that can be brought forward to show that eating the flesh of animals slaughtered while suffering from the active and virulent form of phthisis, or sucking their milk while yet alive, might not be followed by dangerous results, so that some restriction does seem imperatively necessary. But looking upon the extreme difficulty of the matter from many points of view, does it not seem clear that a regular radical and sweeping measure, at least to begin with, would be wiser, and that there should be a limit to the restrictions until a better knowledge of the subject is attained to?—otherwise the thing looks quite impracticable, as it seems certain there would, as the matter stands meantime, be no end of hardships through blunders, misconceptions, misunderstandings, &c. Few things, however beneficial, can be arrived at all at once, and I think it might probably be going far enough at present to make it compulsory for owners of animals to give due notice about suspicious animals and as soon as they show positive symptoms of the malady make it compulsory to either have them slaughtered, and their carcasses buried, or put under proper treatment for a reasonable period, and if the disease becomes even arrested, have them quickly fattened and sent to the fletcher, and if it is not arrested, to have them destroyed, and their carcasses buried. I have no great belief in the ordinary contagiousness unless a healthy animal be kept in continuous contact with a diseased one—say, tied up in the same stall together, the diseased one having a stall to itself, or, better still, a separate apartment of the building, there need be little fear of infection. My views regarding milk taken from a cow in active consumption, even although it may be free from any organic contagion, is that it is not fit for human food, but if the disease respond to treatment and the animal becomes—if you will, so-called—cured, or the malady arrested and quiescent, then I consider it harmless. I have drunk such milk with composure and relish. If, however, there are signs shown of tubercular liquefaction, or small tubercles be detected in the glands of the udder, &c., I would look upon the matter with the greatest suspicion. I do know there would be difficulty, and indeed seeming impossibility in having every case tested microscopically; but ought there not to be more general knowledge of how dangerous tuberculous really is, as it would seem to be not merely a shilly-shally policy, but a perfect absurdity, to place under restriction as dangerous every animal that might have the misfortune to be suffering from any sort of tumour, that seem so often to be looked upon as tubercular or scrofulous, and dangerous in, may it be said, less practical part of the globe.—I am, &c.,

J. H.

—North British Agriculturist.]

DAIRY LESSONS FROM CANADA.

THE advanced report of the Canadian Experimental Farm has still many interesting facts in it relative to dairying, which we were unable to incorporate in our lengthened article on the subject last week. The size of butter globules in milk may appear a matter of no practical importance to many people at first sight, but they have, nevertheless, their functions to perform and their tales to tell. Professor Brown prefaces his advance notes of his experiments with illustrations of butter globules in the milk of twelve breeds of cattle, and these show that, as regard large globules, the shorthorn and Aberdeen polled breeds hold a high place over the standard. The Jerseys and Holsteins are almost equally high; still all these four breeds differ materially in the proportion of small globules.

It is rather singular that the two best beef-making breeds should, as regards butter globules, be classified as the two extremes. It is not so surprising to see the black polled breed taking the lead as it is to find the popular Hereford lowest, for it is commonly the case that a good beef-maker is a rich milker.

To what extent does the size of butter globules influence the time occupied in churning? This question is one of great importance to dairymen. During the past six months an exact record has been kept on the Experimental Farm of the time occupied in churning butter from all sources, at a temperature of 62 deg., and the results are produced in tabular form in the work before us. The average time occupied in churning in winter was twenty-five minutes, but five minutes more were required in summer. This difference in time is not easily accounted for, but it is suggested by Professor Brown to be due to the length of time intervening between the date of calving and that of churning. The record shows that in every case but one, time and size of globules agree with remarkable exactness—the short time and the large globule being inseparable. The one exceptional case referred to is that of the Holstein cow, whose milk possesses larger globules than four of the other breeds tested, but which required an average of

40 minutes to churn. The milk of the Guernsey, which is far and away ahead of that of all the other breed—which include in this instance Guernsey, Jersey, Ayrshire, Devon, Holstein, shorthorn, and shorthorn grade—required the least time—only ten minutes; while in the opposite extreme we find the shorthorn grade, whose milk is least in size of globules, and which consequently requires so long as forty minutes churning. The third position is accorded the celebrated Ayrshire among the seven breeds, as to the size of globules and the time occupied in churning, the latter being twenty-two minutes. The shorthorn is lowest in the list but one—the shorthorn grade—the time spent in churning its milk being forty minutes. The prosecution of such a study as the foregoing facts afford is not only scientifically interesting, but is of direct practical value to dairymen, for, as Professor Brown points out, they unquestionably have something to do with the ripening and keeping properties of cheese as well as butter.

With the view of discovering the suitability of winter milk for the manufacture of cheese, and also ascertaining the breed of cattle richest in cheese-giving properties, extensive experiments have also been made. Ten breeds of cattle were attached, and in his commentary on the results, Professor Brown says:—The Jersey seems to bow to nothing—not even in cheese and solids in winter, for, taking an average of the rennet in chemical testing, its mean of 11.85 is considerably over all others. The Devon has rarely been second in cheese in our experience, and now again takes a lead, subject only to a fuller Guernsey record. The nearest agreement of rennet and chemist is in the case of the Ayrshire and Aberdeen poll. The Ontario farmer will note with satisfaction the position taken by the shorthorn grade, nor will he be displeased at that of the ordinary cow, whatever that may be. The Galloway and shorthorn are close competitors, the former leading.

The comprehensiveness of the experiments is indeed remarkable. Almost every phase of the dairy industry is firmly taken up, while they extend to other branches of agriculture. In the feeding of calves with skim milk, experiments were conducted for a period of six months beginning in November last year, from which stockmen cannot fail to derive a valuable lesson. The calves—shorthorn grades—one bull and one heifer—were allowed three days with their mothers before being supplied with skim milk. The milk was warmed and supplied in two meals at the daily rate of 19 lbs., along with a teaspoonful of oatmeal, 1½ table-spoon linseed meal, 1½ table-spoon molasses. This mixture was supplemented with quantities of clover hay until the twelfth week, after which their provender was increased by the use of bran and roots, with hay. The object of the experiment was, if possible, to make a good calf at less cost than by giving it full ration of milk from the cow, and Professor Brown, referring to its results, says:—

A calf gained 304 lbs., with skim-milk and other food; the food other than the milk cost 2 dols. 8½ cents. The calf, as real, is worth 15 dols., so that we received 11 dols. 77 cents for the milk consumed. This is the lowest possible use of the milk. Were the calf retained for breeding, or for a store steer, its value is invariably placed at one-third more than real price, so that in this case we find the value of the milk to be 9 dols. 90 cents. Then again, supposing the calf had got the whole of the full milk with the roots, bran, and hay only, its production would have cost 20 dols. 17 cents, but by taking the cream from the milk and selling to a butter factory, and by adding other concentrated foods to the milk, the calf was produced for 11 dols. 82 cents. On an average of methods representing the value of skim-milk, we got the sum of 11 dols. 34 cents, so that skim-milk was fairly valued at one-half that of the full milk is borne out by this test. We are satisfied that on an average of winter and summer conditions, for the usual six months of a factory run, each cow will return 7 dols. more by supplying cream and giving with the skim-milk some such additions as we have shown.—North British Agriculturist.

HOLLOWAY'S OINTMENT AND PILLS.—In all outward complaints a desperate effort should be made to at once remove these annoying infirmities, and of establishing a cure. The remarkable remedies discovered by Professor Holloway will satisfactorily accomplish this desirable result, without any of those dangers or drawbacks which attend the old method of treating ulcerative inflammations, scrofulous affections, and venereal eruptions. The most timid invalids may use both the Ointment and Pills with the utmost safety with certain success, provided a moderate attention be bestowed on their accompanying directions. Both the preparations soothe, heal and purify. The two assist the system materially in affecting cure, and restoring strength by helping exhausted nature just when she needs such succour.

WHAT IS THIS DISEASE THAT IS COMING UPON US?

Like a thief at night it steals in upon us unawares. Many persons have pains about the chest and sides, and sometimes in the back. They feel dull and sleepy; the mouth has a bad taste, especially in the morning. A sort of sticky slime collects about the teeth. The appetite is poor. There is a feeling like a heavy load on the stomach; sometimes a faint all-gone sensation at the pit of the stomach which food does not satisfy. The eyes are sunken, the hands and feet become cold and feel clammy. After a while a cough sets in at first dry, but after a few months it is attended with a greenish coloured expectoration. The afflicted one feels tired all the while, and sleep does not seem to afford any rest. After a time he becomes nervous, irritable, and gloomy and has evil forebodings. There is a giddiness, a sort of whirling sensation in the head when rising up suddenly. The bowels become constive; the skin is dry and hot at times; the blood becomes thick and stagnant: the whites of the eyes become tinged with yellow, the urine is scanty and high-coloured, depositing a sediment after standing. There is frequently a spitting up of the food, sometimes with a sour taste, and sometimes with a sweetish taste; this is frequently attended with palpitation of the heart; the vision becomes impaired with spots before the eyes; there is a feeling of great prostration and weakness. All of these symptoms are in turn present. It is thought that nearly one-third of our population has this disease in some of its varied forms. It has been found that medical men have mistaken the nature of this disease. Some have treated it for a liver complaint, others for kidney disease, etc. etc., but none of the various kinds of treatment have been attended with success, because the remedy should be such as to act harmoniously upon each one of the organs, and upon the stomach as well: for in Dyspepsia (for this is really what the disease is) all those organs partake of this disease, and require a remedy that will act upon all at the same time. Seigel's Curative Syrup acts like a charm in this class of complaints, giving almost immediate relief. The following letters from chemists of standing in the community where they live show in what estimation the article is held:—

John Archer, Harthill, near Sheffield:—I can confidently recommend it to all who may be suffering from liver or stomach complaints, having the testimony of my customers, who have derived great benefit from the Syrup and Pills. The sale is increasing wonderfully.

Geo. A. Webb, 141, York-street, Belfast:—I have sold a large quantity, and the parties have testified to its being what you represent it.

J. B. Metcalfe, 55, Highgate, Kendal:—I have always great pleasure in recommending the Curative Syrup, for I have never known a case in which it has not relieved or cured, and I have sold many gross.

Robt. G. Gould, 17, High-street, Andover:—I have always taken a great interest in your medicines, and I have recommended them, as I have found numerous cases of cure from their use.

Thomas Chapman, West Auckland:—I find that the trade readily increases. I sell more of your medicines than any other kind.

N. Darroll, Clun, Salop:—All who buy it are pleased, and recommend it.

Joe. Balkwill, A.P.S., Kingsbridge:—The public seem to appreciate their great value.

A. Armstrong, Market-street, Dalton-in-Furness:—It is needless for me to say that your valuable medicines have great sale in this district—greater than any other I know of, giving great satisfaction.

Robt. Laine, Melksham:—I can well recommend the Curative Syrup from having proved its efficacy for indigestion myself.

Frickheim, Arbroath, Forfarshire, Sept. 23, 1882.

Dear Sir,—Last year I sent you a letter recommending Mother Seigel's Syrup. I have very much pleasure in still bearing testimony to the very satisfactory results of the famed Syrup and Pills. Most patent medicines die out with me, but Mother Seigel has had a steady sale ever since I commenced, and is still in a great demand as when I first began to sell the medicine. The cures which have come under my notice are chiefly those of liver complaint and general debility.

A certain minister in my neighbourhood says it is the only thing which has benefited him, and restored him to his normal condition of health after being unable to preach for a considerable length of time. I could mention also a great many other cases, but space would not allow. A near friend of mine, who is very much addicted to costiveness, or constipation, finds that Mother Seigel's Pills are the only pills which suit his complaint. All other pills cause a reaction which is very annoying. Mother Seigel's Pills do not leave a bad after-effect. I have much pleasure in commending again to suffering humanity Mother Seigel's medicines, which are no sham. If this letter is of any service, you can publish it.

Yours very truly,

(Signed) WILLIAM S. GLASS, Chemist.

A. J. WHITE, Esq.

15th August, 1883.

Dear Sir,—I write to tell you that Mr. Henry Hillier, of Yatebury, Wilt, informs me that he suffered from a severe form of indigestion for upwards of four years, and took no end of doctor's medicine without the slightest benefit, and declares Mother Seigel's syrup which he got from me has saved his life.

Yours truly,

Mr. WHITE.

SARSAPARILLA.

WILKINSON'S

ESSENCE OR FLUID EXTRACT OF RED JAMAICA SARSAPARILLA

IS THE ONLY PREPARATION RECOGNISED BY THE FACULTY AS A WONDERFUL PURIFIER OF THE HUMAN BLOOD.

IT is not too much to say that those suffering from the effects of TROPICAL CLIMATES such as TORPID LIVER, DEBILITY, APOPLEXY, Eruptions, LEUCODERMA, &c., will, by taking this extraordinary ESSENCE OF RED JAMAICA SARSAPARILLA, soon find relief, and ultimately a cure. It is asserted by those who take a little DAILY that the system becomes less liable to attacks of illness.

"We cannot speak too highly of it."—*Lancet*.

"We recommended your Red Jamaica Sarsaparilla."—*Medical Review*.

"The only preparation for removing what may be called the mercury of a mercurial course."—*Sir R. Martin*.

The late Lord Clyde, writing for a further supply of Wilkinson's Sarsaparilla, says:—"I am never without it, for, when feeling depressed or out of sorts from anxiety or fatigue, a dose or two animates me."

"Your Essence of RED JAMAICA SARSAPARILLA cured me of a Torpid Liver; all other remedies failed."—*Earl of Aldborough*.

Prepared only by

THOMAS WILKINSON,

(MEMBER OF THE PHARMACEUTICAL SOCIETY.)

270, Regent-street, London.

SOLD IN SMALL, MEDIUM, AND LARGE BOTTLES.

Caution.—Many spurious, worthless, and injurious preparations are offered to the Public; see that both bottle and label have the name and address, also Trade Mark (W. in a diamond) at the bottom of the bottle.

Wilkinson's Bronchio-Thoracic Lozenges.

Agents: Bathgate & Co.; Smith, Stanistreet & Co.; Gobind Chunder Dutt & Co.

To be had of all respectable firms in India.

THE TROPICAL AGRICULTURIST:

A MONTHLY RECORD OF INFORMATION FOR PLANTERS OF

Tea, Cacao, Cinchona, Coffee, India-rubber, Sugar, Palms, Cotton, Cardamoms, Kola, Coco, Cinamom, Nutmegs, Fibrous Plants, and other Products, suited for Cultivation in the Tropics.

[Published at the former Office, Colombo, Ceylon, on or about the last of each Month, Commenced in June 1881.]

"THE TROPICAL AGRICULTURIST" has now an assured position in its large circulation in Ceylon, Southern and even Central and Northern India, the Straits Settlements, Sumatra, Java, Borneo, Northern Australia, Queensland, Central America, Natal, Mauritius, and the West Indies. From all sub-tropical planting settlements, we have had cordial approval of the publication, and an encouraging measure of support. The English, Indian, and Colonial Press have spoken in commendatory terms of the T. A., as also directors of Public Gardens, from Sir Joseph Hooker, F.R.S., downwards, and so have all planters.

No planter should be without it.

Rates of Subscription, including postage, in advance:

£1 Sterling.—Rupees 12;—5 Dollars.

Single copies, 2s. or Re. 1; back copies, 3s. or Re. 1 1/2.

Any one of the four volumes completed, bound in cloth, stitched, with comprehensive index, for £1 10s. (or Re. 18), carriage prepaid. As a medium for English, American, and Australian ADVERTISEMENTS of goods suitable for the tropics, India, as well as Ceylon, the Straits Settlements, Java, and West Indies (Central America being included in that term), or connected with agriculture, the Tropical Agriculturist stands unrivalled, the work being constantly in the hands of Native as well as European and American agriculturists. Being a monthly Periodical, the Tropical Agriculturist lies on the table, and is very often referred to during each month, a fact which advertisers will know how to appreciate.

For the sale of plants, seeds, machinery, implements, &c., used in tropical (tea, sugar, fibres, &c.) agriculture, no better advertising medium exists.

Rates for Advertisements.

CALCUTTA:—SATURDAY, OCTOBER 24, 1885.

[No. 43.]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING 14TH OCTOBER 1885]

Madras.—General prospects fair; continue favourable in Bellary and Anantapur.

Bombay.—Rain throughout the Presidency, excepting Sind; *harif* crops generally doing well, and sowing of *rabi* crops in progress. River falling in Sind, and crops suffering in parts of Karachi and Hyderabad from deficiency of water, standing crops damaged by rats and storms in parts of Hyderabad, and by blight in parts of Ratanagiri. Cholera and fever in parts of thirteen and cattle-disease in parts of ten districts.

Bengal.—Slight and not general rain during the week. A little more rain is now wanted in some places. Prospects of *amra* rice and other standing crops generally favourable except in the flooded parts of Burdwan and Presidency divisions. *Shadoi* outturn not very fair, on the whole, as the crops in many places suffered from excessive rain and flood in August and September. Cultivation of *rabi* crops being carried on vigorously. Price of rice improving slightly in some districts. Prevalence of fever reported in many places.

N.-W. Provinces and Oudh.—Slight rain in places. General prospects fair. Cholera, fever, and cattle-disease continue in places. General health fair.

Punjab.—Slight rain in the Rawalpindi, Dera Ismail Khan, and Peshawar districts. Fever prevalent in the Delhi and Peshawar districts and in the Kohat tahsil of the Rawalpindi district; a few cases of cholera in Bhilwari and of cattle-disease in Rajwal, in the Simkot district. Crops suffering from want of rain in the Ferozepore and Talwar districts. *Rabi* operations in progress. Prices fluctuating.

Central Provinces.—Rain has fallen in northern and western districts, and crops are improved, it is much needed in Chhattisgarh and especially in Bilaspur, where crops on highlands are reported to be lost. Prospects of *amra* rice, and *neera* steady.

Hyderabad.—Fever severe in three districts, slight in five districts; elsewhere public health good. Cattle-disease slight in eight districts; elsewhere health of cattle good. Crop prospects good. Rains seasonable.

Assam.—Weather seasonable. Public health good; cattle-disease still in some localities. State and prospects of crops favourable. Days warm, nights cool. Prospects of *amra* crops fair. Tea doing well. Common rice 14 seers @ 5.5 chittacks per rupee. Land being prepared for mustard.

Myore and Coorg.—Good rain fell throughout the State; about 24 small tanks reported to have braced in the Kodur district. Standing crops improved by the rain; horse gram and *ragi* are generally being sown; paddy seedlings transplanted in Salmara, and paddy sown in Kadur. Ploughing operations and cultivation in progress in the Bangalore district. Prospects of the season and public health good, 6 cases of cholera reported in the Shimoga district; cattle improving in condition, but murrain still prevails in parts of the Shimoga and Kodur districts. Prices throughout show a tendency to fall, and in Tanjur district the price of *ragi* is reported to be rapidly falling. Crops in good condition. Cardamoms being picked.

Berar and Hyderabad.—Weather clear in Amraoti. Prospects of crops favourable; *rabi* sowings in progress. Wheat 22 and *neera* 10 seers per ropas. Rain throughout the district of Akola has done good. Standing crops good, *ragi* seedlings commenced in Hyderabad, sowings postponed in Patbur along on account of incessant rainfall. General health fair. Cows rice 12½, white *neera* 17½ yellow *neera* 24½, and *lar* 17½ seers per *chittack* rupee.

Central India States.—Prices stationary. Late rainfall has much improved the prospects, but water in wells and tanks is very low. Cholera at Rewah, 12 cases, 7 deaths. Rain much wanted in some parts. Prospects of crops improved in Sehora. *neera* 10 seers a. ag. Health good. Crops and sowing prospects much improved. Late rain in Manipore, where murrain is removed.

Rajputana.—Rainfall scanty in nearly all parts. Tanks, wells, health and crops good in parts. Cholera almost disappeared. Crops seriously damaged from want of much required rain in Marwar. Prices rising. Crops withering from want of rain in Meywar. Indian crops being cut, about 4 *anna* crops. *Rabi* withering and very poor. *Rabi*

sowings commenced, but not promising. Tanks decreasing in parts. Rain very greatly needed in Harowli, fever is prevalent. Tanks and wells drying in Korowli. Fever prevalent. *Shadoi* crops damaged. Rain urgently required. Tanks drying. Wells decreasing. Crops withering from want of rain in Dholepore where fever continues. Nepal.—Prospects good. Cholera has ceased.

Letters to the Editor.**THE COFFEE BUG.**

TO THE EDITOR.

SIR,—A gentleman, signing himself, "AN ANXIOUS SKEUMER," writes to me from Ceylon, and asks me to suggest a remedy for the destruction of a bug (a species of *coccini*), which commits great ravages among the coffee plantations. In reply, I beg to advise him, through the medium of your valuable paper, to plant malberry trees among the coffee plants, when the insect will immediately forsake the one and fasten on to the other. They may also be killed with the fumes of tobacco and sulphur. I take this opportunity to inform the public (who take an interest in agri-horticultural matters), seeking information from me on these subjects, should do so through your valuable columns, so that not only individuals, but the public at large, may have the benefit of any suggestions it may be in my power to offer.

HEM CHUNDER DUTTA.

Calcutta, October 14, 1885.

TEA-PLANTING.

TO THE EDITOR.

SIR,—Will your correspondent, Baboo Hem Chunder Dutta, kindly enlighten me, and a number of would-be Tea speculators on the following points:—

- (1) What is the best climate for tea cultivation?
- (2) What is the best manure?
- (3) Would it be safe and healthy for the owner of a tea garden to live on the estate?
- (4) Is elevation necessary for tea cultivation; if so, to what extent?
- (5) What labor would be necessary?
- (6) What amount of profit would a speculation in tea yield?

A WOULD-BE PLANTER.

NOTE.—With such entire ignorance of the subject, we should not ask you to launch into tea cultivation. Better try something else, which you have some knowledge. If, however, you are determined to try tea, procure a copy of the *Tea Planter's Vade Mecum*, recently published by the Editor of the *Indian Tea Gazette*, 16, Bore-street, Calcutta.—ED., I.A.

FOOT-AND-MOUTH DISEASE.

TO THE EDITOR.

SIR,—Will any of your numerous able correspondents enlighten me and a number of agriculturists as to the causes, symptoms, and cure of foot-and-mouth disease in cattle?

I hope your able correspondent, Doctor Baazila, of Etawah, will kindly oblige us with the information I seek.

AN AGRICULTURIST.

Burdwan, October 20, 1885.

NOTE.—A reference to the *Indian Agriculturist* for 1884, pp. 124, 146, and 412, will give some information on the subject. But for the convenience of our readers, we have summarized the information, which will be found among our editorial notes.—ED., I.A.

Editorial Notes.

THE net amount of Indian sea and land customs revenue, exclusive of the salt revenue, for the first six months of the current official year, amounted to Rs. 51,22,000, as compared with Rs. 42,41,000 during the corresponding period of last year.

PROFESSOR WALLER has replied to the letter of "J. H." in the columns of the *North British Agriculturist*, on the subject of tuberculosis in cattle. The continuation of the leading article on the same subject by the Veterinary editor of that journal bears out the Professor's conclusions in all respects. We reproduce both articles elsewhere.

FROM local enquiries made, it is found that about 300,000 bigahs of paddy have been lost in Oolcoobaria sub-division of the Howrah district, besides other crops. In the Midnapore district prospects are everywhere good outside the flooded tracts. At Jehanabad there has been great loss in half of the sub-division. The report of the state of the crops in other parts of the province is pretty fair.

THE trade returns of Victoria shew a considerable falling off. The imports for the month of August show a decrease of £131,967, and the exports £212,040, as compared with the corresponding month last year. The decrease in the exports is entirely due to a falling off in gold and wool, for in articles of general merchandise there was an increase. The agricultural prospects throughout the colony are reported as excellent, and a revival of trade is shortly anticipated.

WE are informed that the annual Horse-Show at Rajkot was to have come off on the 22nd instant. An influential committee, with the Political Agent for Kattywar at its head, and including among its members, the Thakores of Palitana, Limari, and Rajkot, has been appointed. The princes of Kattywar are well known for their love of horse-flesh, the royal paddocks of Bhownagpur, Gondal, and several other States containing as good specimens of the equine tribe as might well be found in any other part of India. This is not the only reason for expecting that the Show will in all probability be worthy of Kattywar. The offer of substantial prizes to the poorer class of exhibitors will, no doubt, afford them a sufficient inducement to bring their animals to the Show.

JUDGED by the figures quoted by a contemporary, the export trade of the Central Provinces during the second quarter of the current year, shows a marked decrease—something like 19 lakhs of maunds, the greater part of which is due to a falling off in wheat and cotton. The quantity of wheat exported was 3,162,951 maunds, compared with 4,244,395 maunds, during the same period last year. That of cotton exported amounted to only 6,988 maunds against 39,507 maunds last year. Rice and linseed also show a slight falling off. The imports, on the other hand, show a small increase. This is said to be chiefly due to the large quantity of *goor*, or undrained sugar, received from the N.-W. Provinces into the Jubbulpore and Nerbudda districts.

ACCORDING to the last census, it appears that the population of the kingdom of Italy numbered 28,459,628, of whom 8,173,382 were engaged in agriculture, exclusive of children aged less than nine years. Of this agricultural population 1,325,879 are reported as cultivating their own lands; cultivating on shares with the proprietors, 1,045,330, and 401,643 are tenants. The labourers number over 5,000,000, of whom a little more than half are reported as engaged in steady labour, leaving nearly one-half engaged irregularly. Another division is given of the agricultural population as consisting of landed proprietors, who number 4,132,432, of whom, however, only 2,668,696 are represented as owning both lands and buildings, the rest consisting of those who own only the land without the building, or vice versa.

AN interesting paper lately read at a meeting of the Saxon Economical Society in Dresden, gives an account of the introduction of the potato into Germany, and the gradual spread of its cultivation. In 1685 it was first brought into Germany from Italy. The first seed potatoes in Saxony were a present in 1691 from the Landgrave of Hesse to the Elector of Saxony. In 1647 they were grown as exotics in gardens at Leipzig. Swedish soldiers brought them into western Germany about the conclusion of the Thirty Years' War. In 1717 they were re-introduced into Saxony from Brabant, and within twenty-five years they began to be regularly cultivated, their use being much developed in the famine period of 1770-71. In the year 1882 over 9,000,000 acres were given up to the cultivation of potatoes in Germany, the produce amounting to 22,000 tons.

THE experiments with Manilla hemp (*Musa textilis*) in Southern India have been noticed by us from time to time. In 1882 plants were sent from the Saidapet Farm to the Government of Bombay for experimental cultivation in that Presidency; and from a reply recently sent by the latter to an enquiry of the Madras Government we find that, although the experiment was not an unqualified success, yet the plant had been found to thrive well in certain parts of Western India, and has established itself to a considerable extent. Nothing has, however, been done in the way of extracting the fibre as yet; but as Mr. Ozanne, the Director of Agriculture, has suggested that future experiments with the *Musa textilis* are to be confined to the Government Experimental Farms at Bhadgaon and Hyderabad (Sind), the Botanic Gardens, Poona, and the farm attached to the Poona College of Science, we may expect before long to hear something more satisfactory on this subject.

THE agricultural statistics of New Zealand for the year ending with March 1885, show that the area under wheat fell off by 107,663 acres—from 377,706 acres to 270,043 acres, as compared with the area in 1884. Yet the yield is very high—26 bushels per acre in 1884, and 25-25 bushels in 1885. Oats, on the other hand, increased in area from 262,954 to 354,704 acres, and barley from 32,907 to 39,703 acres. The export trade in foreign meat has led to an increase of pasture and root crops, to provide for the keeping of more sheep, which have increased from 12,384,075 in 1884 to 14,106,337 in 1885. An increase of 722,262 in one year, in spite of the large number exported in carcase form, must be regarded as very satisfactory.

WE learn that the system inaugurated last year, in the South Canara District, of establishing depôts at different points for the receipt and purchase, at certain fixed rates, of minor forest produce, such as myrabolams, wax, honey, &c., collected in the forests and brought to the depôts, bids fair to become in time an extensive industry, as it has already developed to a considerable extent, so much so that it has been found necessary to employ an additional establishment of clerks to keep account of the quality of produce brought in by the gatherers. Satisfactory as the undertaking promises to be from a revenue point of view, it is also found to serve as a check on forest fires, the gatherers of such produce being naturally anxious to protect from fire, as much as possible, the trees from the produce of which they earn a livelihood. Wanton damage to trees, so common, is also to a great degree prevented. The system will probably be extended in time to other districts, the Conservator being anxious to do so.

IT is stated that in the Assembly of South Australia on September 2, the Commissioner of Crown Lands obtained leave to introduce a Vermin Destruction Bill, and made a startling statement in connexion with the increase of vermin, which is proceeding at a frightful pace, all attempts to reduce it being futile, and, in fact, rather encouraging than checking it. Interested persons are propagating vermin by taking them in cart-loads and letting them loose in the country. Fraud seems rampant, and vermin and carts being made use of by skilful men to cheat the Government by obtaining bounties. Vermin are said to be brought in loads over the Victorian border. The Vermin Board have failed this year to collect from the land-

holders, and spent it all, besides the amount supplied by the Government, the payments reaching alarming sums. The new Bill will repeal the existing legislation, and revive the Act of 1870, which throws upon owners and lessees of land the responsibility and the expense of killing vermin.

.

We learn from a Madras paper that Monsieur Reynaud, Professor of Agronomy at Pondicherry, has raised some strong healthy plants from the seed of the Chinese "milk plant" (*de soya*). It is a native of Japan *Yeu Lou*, the Chinese use it largely, expressing the milk, which is used in its liquid state, and is also manufactured into cheese, it has not yet, however, found favour among Europeans, the flavour being unpleasant. The Chinese bamboo *Kajany*, has also been raised from seeds by M. Reynaud, this particular bamboo grows to an enormous size, and is valuable for a variety of purposes—all kinds of utensils are made of it—casks, tubs, buckets, troughs, &c. The Angola beans (*Oytine Cassen*) sown a short time ago are thriving satisfactorily, and a good gathering is expected. They are by far the best beans for *haricot* and many other French dishes, a great recommendation is their easy digesting qualities and pleasant taste. The plant continues to bear for seven years, and is greatly prized in the Antilles for its economical usefulness, it requires little or no tending.

.

A CONTEMPORARY says—If we consider the railway mileage of each country in proportion to every square kilometre of land, we shall find that Belgium comes first with 145 kilometres of railway, Great Britain with 95, France with 50, Germany with 80, the smallest European States being Russia and Norway with 0.3. The United States, with all its enormous network, now only figures for 2.1 and Canada for 0.2, while Brazil, the Argentine Republic, Paraguay, Japan, and Queensland are only 0.1 each. But if we view the subject from another standpoint—viz., that of the mileage to every 10,000 inhabitants—the position of affairs is singularly reversed. Queensland, which was at the bottom of the world's list in the former instance, now stands at the top with 70.8 kilometres of rail to every 10,000 people, South Australia 50.1, West Australia 49.8, New Zealand 41.7, New South Wales 31.1. The United States show for 36.8, and Canada 29.4. Naturally the European States are very low in the scale under this aspect, Great Britain being only 8.5, France and Germany 7.9 each, Belgium 7.7, Holland 6.0, Russia 3.0. The lowest of all is India with 0.7.

.

The concluding portion of Colonel Hunt's lecture on Stock Farming in India will be found among our selections this week. It is perhaps needless to say that the subject chosen by Colonel Hunt is a most important one for India, and should receive careful attention. The lecture is a thoroughly practical one, and the subject has been handled in a manner to leave no doubt in the minds of those who assembled to hear the speaker, that he had a thorough grasp of the matter in hand. The account of the ensilage experiment, which was quite a success, brings to light one important point, viz., that silage improves by keeping—it may take so far as the point, pungent smell is concerned, and that the *quality* of the fodder ensiled, has an important bearing upon the quality of the silage produced [*Vide* paras 5 and 6 of Captain Murrells' "Notes on Ensilage at Hissar, during 1884-85," embodied in the lecture]. In our opinion, Colonel Hunt's lecture should be widely circulated.

.

A CORRESPONDENT, whose letter will be found elsewhere, wishes to obtain some information on the causes, symptoms, and cure of foot-and-mouth disease in cattle. Some time last year, Mr. George Fleming, F.R.C.V.S., President of the Royal College of Veterinary Surgeons, wrote to the *North British Agriculturist*, saying that "those who have most carefully studied the history of, and are best acquainted with, this disease, do not agree on the spontaneous origin theory of this malady. He was of opinion that its continued prevalence was due to imperfect sanitary measures or neglect in their application. He did not, however, mention the causes, symptoms, or cure. But a correspondent of the *Planters' Gazette* last year recommended sulphuric acid as a cure for foot-and-mouth disease in cattle. Two ounces of the acid should be put into a quart bottle, which should then be filled up with water, and a table

spoonful of this dilution given three times a day to the diseased cattle. He found this remedy completely efficacious. In addition to giving the acid internally, he advises the moistening of the affected part with the same dilution, applied with a sponge (care should be taken, however, not to confound sulphuric acid with sulphuric acid, as the latter would be productive only of mischief. He went on to recommend the burning of a little sulphur once or twice a week in cattle sheds, as a prophylactic for the disease.

"Take a slip of card-board, or of extra stout brown paper about a foot long and two inches wide, and place on one extremity about as much coarsely powdered brimstone as would lie on a penny piece, hold it by the other end, and apply the flame of a candle till the sulphur is ignited, and then wave it about in the shed in order to disperse the vapour among the cattle. If there be straw, or anything else inflammable about, hold it close, or something of the sort, in the other hand, under the burning sulphur, to catch any that may drop."

.

Dr. F. Kraus, president of the Homoeopathic Medical Society of Kansas, recommends that cattle affected with foot-and-mouth disease, be bled all over with good strong vinegar frequently, and that the mouth be syringed with vinegar several times each day, or as often as may be necessary to remove the slime therefrom. The feet and claws, when affected, should also be washed with the same liquid. For a drink he recommends that a pound of salt be put into a gallon of vinegar, and allowed to rest there. Then, after stirring well, put from one to four table spoonfuls into every pail of water that the animal drinks, and keep plenty of salt within reach. Vinegar should be sprinkled freely all about the stable, and such as is derived from fermentation should be used. Cattle that have been exposed to the disease may be watered with the non-mixed preparation. It is further recommended that the diseased animals be given chlorate of potash and phosphate of potash alternately, using the third or sixth decimal trituration. Of each of these salts, take of the size of a pea every morning, and put each separately in a bottle containing a half pint of water. It is necessary to keep two additional bottles for a liniment, which should be slushed carefully every time they are used. Give the two prescriptions alternately six or eight times a day, each time pouring into the administering bottle one sixth or one eighth of the daily prescription; then fill the bottle with water and shake thoroughly. When recovering, animals should have, every morning, phosphate of lime of one-sixth trituration in one half cup of water. With these two methods of treatment to go upon, our correspondent and his friends may be able to effect some good. We shall, however, be very glad to receive the opinions of our numerous readers upon the subject—especially in regard to the causes and primary symptoms of the disease.

.

The study of agriculture, in theory and practice, is now engaging the attention of the Ceylon Government, and a local contemporary informs us that instruction in the principles of agriculture, in a practical manner, as suggested by Mr. H. W. Greene, the Director of Public Instruction in Ceylon, is making satisfactory progress throughout the island. Further, this system is directly encouraged by the local Government, and suggests that it might to some extent be adopted in this country. He goes on to say that, since January last, theoretical agriculture has been taught in every Government vernacular or Anglo-vernacular school in the higher standard, the text book in use being Mr. Greene's primer. As another means of encouraging the study, all teachers are compelled to pass an examination in theoretical agriculture before they can obtain a certificate. Practical agriculture is also taught as well as theoretical, and at the Colombo School of Agriculture this year the students have been taught the use of certain new ploughs, and have been engaged in practical experiments. As soon as competent teachers can be provided, Mr. Greene proposes to ask permission from the Government to set aside some practical agriculture at several other schools, a piece of land being allotted to each school, and part of the produce being given to the teacher so as to induce him to take a real interest in the proper working of the land.

A CONTROVERSY has been going on in the columns of the *Englishman* under the curious title of "The Exodus of Bones." Mr. D. B. Allen, of the Bengal Agricultural Department, raised the question of bones as manure, and thought that the quantities annually exported from the country might be applied with better results as manure. This was followed up by a correspondent, signing himself "L. L.," who took the same view as Mr. Allen. We noticed both letters, and took occasion last week to observe that both these gentlemen had apparently overlooked a very important item for the fertilization of soils in the municipal sweepings which are daily carried away out of this city, and practically wasted. In the last letter on this subject signed "D. B.," the writer has taken the same as ourselves. We reproduce this letter among our selections, and hope it will be carefully read by members of the Bengal Agricultural Department. The truck-loads of refuse carried away daily by the Port Canning Railway might be more usefully utilized in fertilizing fields round about Calcutta. What is easier than to heap up all that refuse in open fields; set fire to it, and utilize the ashes in manuring fields? The ashes thus obtained would be found to contain the most essential properties of the best manures; while, from a sanitary point of view, it would be much better to bring the refuse of the city to this use, than to pollute the river Hooghly with it, as is the case under the present system of getting rid of it.

THE Mauritius Government evidently have a good eye to business. The Hon'ble W. Newton, President of the Chamber of Agriculture in this island, has drawn up a pamphlet entitled "La Crise Sucrière," in which he suggests certain measures for dealing with the crisis in the sugar industry. One of these suggestions is that it should be made known in India that animal charcoal is not used in the manufacture of sugar in Mauritius, so that it ought to recommend itself to the natives of India, who, on account of their religious prejudices, would give it preference over most other sugars in which animal charcoal forms a prominent feature in the manufacturing process. In order therefore to give this matter as wide publicity as possible, the Mauritius Government have requested the Madras Government to make it known in India. We are not sure that the natives of India attach very much importance to the use or otherwise of animal charcoal. When sugar factories were first started in this country, there was some reluctance on the part of the natives to use sugar manufactured under this process; but at the present time, western civilization has done much towards removing such scruples, and "religious sentiments," as far as we are aware, do not prevent their using the sugar manufactured by the Cossipore and other factories. We are therefore of opinion that if the Mauritius Government intend exporting their sugar to India, the only consideration likely to have any weight with the natives, will be cheapness; for it must be remembered that India is a sugar-growing country, and cheapness is a very important item with the natives.

MR. J. K. BOYLE, the Assistant Secretary to the Colonial and Indian Exhibition, has addressed a letter to the Government of India on the subject of the proposed display of live fish and of fish-hatching apparatus at the forthcoming Colonial and Indian Exhibition, and stating that the Royal Commissioners will gladly arrange to receive any living Indian fish, should it be found practicable to send any over. He at the same time forwarded a circular letter from Mr. Chambers, the Secretary to the National Fish-culture Association, giving the names of several Indian fish which have been already, or might with advantage be, introduced into England. The following is a text of Mr. Chambers's letter:—

In relation to our conversation the other day, respecting the importation of Indian fish alive for the tanks in the Aquarium next year, I have to state that the following fish have already been introduced to this country, and are at present thriving well:—

- Ophiocephalus gachua*.—(Indian walking fish.)
- Trichogaster lalius*.—(Rainbow fish.)
- Polyacanthus cupanus*.
- Barbus punctatus*.
- Anabas scandens*.—(The climbing perch.)

Ophremonus trichopterus.

The following could also be easily introduced:—

Ophremonus olivaceus.—(The best edible fish of the East.)

The Situloides.—(Over 100 species, all of which travel well.)

Betta pugnax.—(The fighting fish of Siam.)

There are other Indian fish that might be acclimated, provided ordinary care were exercised. I am sure that the experiment would meet with success if tried.

THE experimental cultivation of Guinea grass on the Western Jumna canal appears to have been attended with better results than have been obtained in similar cultivations in the N.-W. Provinces. In August 1883, a quarter pound of seed was sown in ground manured and ploughed, occupying an area of 0.033 acre, or 128 square yards, divided into *kharis* or beds. The first cutting was taken in the November following, and yielded nearly 3 maunds, or at the rate of 113 maunds per acre. The next cutting was taken in May of the year following, and weighed nearly 3 maunds, while a third cutting in June weighed 3 maunds 3 seers. After this the roots of the plants were separated, and 10 new *kharis* (beds) were planted, equal to 0.033 acre. These were cut in August and September following, and gave equally good results. The total yield from the 8 old *kharis* was nearly 29 maunds, or an outturn per acre of 573 maunds, which may be regarded as very satisfactory. The ten *kharis* of transplanted roots yielded a total of nearly 9 maunds, equal to an outturn of 265 maunds per acre, which is less than half of the outturn from the original 8 *kharis*. The roots were planted in rows at intervals of two feet apart, in soil said to be "sandy and rather poor." Under the circumstances, therefore, the results compare very favorably with those obtained in the N.-W. Provinces, where the outturn per acre was about 350 maunds. It is noticeable that these experiments were made with artificial irrigation, which formed by far the most expensive item in the cost. It is, however, intended to try a plot of ground planted with this grass without artificial watering; and if it is found that good results can be obtained in this way, an important point will have been gained.

THE following is a summary of Messrs. William James and Henry Thompson's fortnightly Circular of Indian tea, dated London, 24th September 1885:—Upwards of 35,000 packages have been catalogued for sale during the fortnight, including 3,500 from Ceylon and 2,500 packages of reprinted tea. The auctions have passed with good spirit, all fine qualities being competed for at firm prices. There has also been a brisk demand for leafy tea under 11d., and for broken teas under 10d.; but not so much enquiry for Pekoes and broken Pekoes between 1s. and 1s. 6d., which in consequence are selling at rather cheaper rates, especially where liquor is wanting. Tea of superior quality continues to come forward from Assam and Darjeeling, and a few of the latest invoices from Cachar show improvement, although the majority are still fluctuating. Transactions have included the sale of 685 chests of fine tea from the Assam Company's Nazareth Factory, at 1s. 9d. average, and 900 chests at 1s. 5½d., the corresponding shipments last season yielding 1s. 5½d. and 1s. 0½d. per lb., respectively. 110 chests from Bishnauth Dikora Division sold at 1s. 11½d. per lb., and 250 chests from Dootarrah sold at 2s. average. Receipts from Ceylon are mostly of improving quality, and are selling at higher prices, averages ranging from 1s. 2d. to 1s. 6d. per lb. The total shipments from Calcutta to 1st September were 13½ million lb. against 16½ millions last season. Arrivals to date (including Ceylon tea) are 14½ million lb., of which 11½ millions are sold. At the Calcutta sale on the 10th instant prices declined; and at the sale on 17th instant they remained without change, the quantity sold being about 25,000 packages, and the average prices obtained 9½ annas. At the corresponding sales last year, 29,000 packages were sold at 9½ annas average.

WE learn from a Bombay paper that the Forest Commissioners are at present circulating a series of notes upon the subject of experiments which Mr. Orange is carrying on. By laying before all interested in the matter what has been done in the way of experiment and research, the Commission hope to gain information

upon local customs:—(1) Regarding the cultivation of rice. (2) Regarding the variations in the manner of preparing rabi and of the materials used; and of the proportions in which each ingredient is used. Consequently, they request that where the cultivation of rice differs from the method adopted in the experiments, they be informed of the points of difference; and, if possible, the circumstances which have caused these differences. A series of questions upon rabi will soon be sent in a similar way, and the Commission invite remarks and criticisms from those competent to offer them. The experiments described in the "notes" have taken place at certain stations which seem judiciously selected. Mr. Ozanne withholds his conclusions as to what deductions may be drawn from the results of the experiments until after the harvest, for not until then will all the data be in his possession. But he thinks that the following statements may be safely made from what he has ascertained by his experiments:—(1) that cowdung rabi is decidedly superior to all other varieties, and that the better the soil and better the season, the more is its superiority exhibited; (2) that plots unrabbed and unmanured are markedly inferior, not only to rabbed plots but to manured unrabbed plots; (3) that manure unburnt is much inferior, as far as any rate as regards the area of transplantation, to manure burnt; (4) that good results are obtained from leaf and grass rabi. These results are much better than I anticipated, but here I must notice that the brushwood used for the rain and faugal plots was not cut early, as the people consider necessary. This fact may also account for the small superiority, nay in cases, inferiority, of rain as compared with faugal."

The following is a summary of the health, crop, and weather reports for the week ending 14th October 1885:—

In the Madras Presidency general rain has again fallen, and agricultural prospects are fair. In Bellary and Anantapore especially great improvement has taken place. In Mysore there has also been good rain. The standing crops have improved; sowing, transplanting, and ploughing operations are in progress, and prospects are now said to be good. In Coorg crops are in good condition. Rain has fallen throughout the Bombay Presidency, with the exception of Sind. The *kharif* crops promise well, and *rabi* crops are being sown. In Sind rain is wanted. In the Berars and Hyderabad the recent rain has been beneficial to the crops, which promise well. Rain has fallen throughout the Central India States, but more is wanted at Neemuch and Agar. In Rajpootana the rainfall has been slight, and limited to a few places. In Marwar, Meywar, Kherwara, Harowli, Kotah, Jeypore, Kherowlie, Dhoolpore, and Bhurtpore, the rainfall has been insufficient, and more is wanted for the crops. In the Central Provinces the rain of the week has been confined to the northern and western districts. Prospects continue fair; but in Chhattisgarh and Raipore more rain is much needed, especially on the highlands. There has been little or no rain in the Punjab during the week. Prospects are on the whole fair; but more rain is wanted in the Ferozepore and Halket districts. *Rabi* operations in progress. Slight rain has fallen in the North-Western Provinces and Oudh, and general prospects are fair. In Bengal a little more rain is said to be wanted in places. Except in flooded tracts, the prospects of *aman* rice, and other standing crops are generally favourable. The *bhadi* cotton generally has not been good, owing to the damage caused to the crops by floods in many places. *Rabi* cultivation is progressing vigorously. In Assam seasonable weather continues, and the crops promise well. In British Burmah crops prospects are good. The public health is on the whole fair. Prices are fluctuating in the Punjab, the Central Provinces, and the North-Western Provinces and Oudh, and are falling in Mysore, and to some extent in Bengal.

According to Forestry, other materials than green food considered suitable for cattle food and used mostly for litter, such as straw, fern, &c., may be packed in the dry silo. Rye-straw thus treated in a proper fashion makes an ensilage which all stock like, and is a specially excellent fodder for cows in milk and lambing time. Old chalk pits with deep sides, a slope-sided shed or building may be easily turned into such a dry silo, or the open stock place would serve. A silo can be made in the bay of a barn by building up the midway as high as the beams, with stout planks well secured, and battened across. The process is as simple as it is old amongst sheep-farmers of Essex and

the eastern counties of England. The material, cut as short as possible, is carried, say, into the barn, where a number of men and boys, each with a wooden rammer in each hand, ram and tread it hard; also finely-powdered salt is scattered over it to the extent of about 1 lb. to the cwt. of chaff; while the water from a fine rose is at the same time gently showered over it. In warm weather, and with dry chaff, a gallon of water to the cwt. of chaff is used. When the chaff rises in the barn, use only half this quantity of water. The whole mass of chaff treated is every night levelled at top. Heavy planks are laid on, at each filling and settling, to compress it. Chains are used fixed to staples in the barn floor; by fixing a screw jack to a link and taking a bearing on the planks, extra pressure is obtained. So hot does this chaff become after a few days that it cannot be comfortably held in it. It will have cooled down in six or seven weeks, assuming a black bronze colour, with an aromatic fragrance; it is then fit for use. It has to be opened at the under side, an American hayknife being useful for cutting into it. If well covered down, it may be kept for two or three years. Waste hay, old malt, dust, fern, lawn-mowings, as well as leaves of mangold-wurzel, pea-hulm, tare-straw, when cut short and added to the matter packed in the silo, increase its appetizing flavour. Rye, besides being thus used in the dry silo, when early sown in August, can be sheep-folded; it may be then in early spring cut green for stock; afterwards a good plant for seed may be had—as we may count four crops from a plant that grows on poor soils, and seldom fails.

The returns of the railway-borne trade of the Bombay Presidency for the quarter ending 30th June 1885, show a remarkable improvement over the other quarters. This is chiefly due to the returns having reference to the driest part of the year. The entire trade of the Presidency has been divided into three heads, and compared with the previous quarter, was as follows:—

	Previous quarter maids.	Current quarter maids.	Difference.
(1) Imports from External blocks.	8,991,615	10,797,930	+ 1,806,315
(2) Exports to Do.	2,088,474	2,787,517	+ 699,043
(3) Local Trade ...	7,425,701	9,847,838	+ 2,422,137
Total maunds ...	18,475,790	23,432,285	+ 4,956,495

Compared with the corresponding quarter of 1884-85, the traffic shows an increase of 1,532,604 maunds, or 7.0 per cent. The trade under the first head is composed of 10,408,387 maunds of principal, and 389,543 maunds of minor commodities, imported from the other provinces, of which the Central Provinces contributed the largest share, and Mysore the smallest. Wheat, oil seeds, grains other than wheat, and raw cotton constitute the bulk of the trade. Compared with the figures for the corresponding period of last year, the total imports show a small decrease in the case of wheat and raw cotton, but a considerable increase in oilseeds. The decrease in the wheat from the Central Provinces, is amply made up for by a corresponding increase from the Punjab, Rajpootana, Central India, N. W. Provinces and Oudh, and Berar. The increase over last year's figures in the exports, or second head, amounted to nearly 325,000 maunds, of which the Central Provinces and the Nizam's territory took the largest share, and Sind the smallest. The exports were chiefly made up of coal, cotton goods, gunny-bags, metals, salt, sugar and tobacco. Compared with the figures of the corresponding period last year, there is found to be a falling off in coal, gunny-bags and tobacco, while the traffic in cotton goods, metals, salt and sugar, show a very large increase. It is observed that the greater portion of the coal exported belongs to the railway companies, while the bulk of the gunny exports represent empty bags returned to the blocks whence wheat, other food-grains, and oilseeds are imported in large quantities. The trade under the third head, local trade, shows an increase of 8.0 per cent over the corresponding period of last year. The increase is principally confined to food grains other than wheat, oilseeds, salt and sugar, while there is a corresponding decrease in wheat and raw cotton. On the whole, the quarter under notice appears to have been a brisk one for trade.

A CORRESPONDENT, writing to the *Pioneer*, bears testimony to the soundness of the views expressed by Colonel Hunt in his recent lecture at Simla, on 'Stock-farming in India.' He says:—

In 1867-68, I got what I believed to be a 1 or 2 bred Romney Marsh ram lamb from a friend at Agra. I forgot how it came into his possession, but he had it as a pet till it became mischievous. I was stationed some distance in the district, and had a private flock of about 60 sheep of sorts which I bred partly as a pastime, but principally for the table. This with some cows I had been improving some five or six years, and even with common country animals, the result was remarkable. I had plenty of good sound grazing, and yearly gathered some tons of hay. On getting the young ram, I took a little more interest in the sheep, and being a North Aberdeenshire man and brought up with sheep in my earlier days, I had some idea of, as well as a liking for, their management. I selected my ewes to what I best thought suited my purposes, and increased my flock (by purchase in the villages) to about 60 good healthy selected ewes. During the first year this was increased to about 75, and in 1873 I had about 220 ewes, scarcely if any inferior to pure bred sheep, the mutton often weighing 140 lbs. (in 2 and 4 teeth) the mutton and fleeces superior to any I have seen at least in India. The sheep had as a rule (less 20 wethers) nothing but grazing, but on coming in at night found a "laik" with plenty of hay in the centre of their enclosure, and in the morning a lump of salt in a trough was offered; sometimes they licked freely, other times passed on. They were very exceptionally free from all diseases even to small-pox; and rot, a common disease in the district, was unknown to them. Among the 20 wethers, 5 were gram (whole) with a sprinkling of salt was allowed every evening, and as one was killed another was put on. The principal difficulty I had was that about 75 per cent of my days I had to be absent from my head quarters for four or five days at a time; then the sheep were left to the care of a servant who made the best of his opportunities. Coming home after a longer than usual absence, I had a very heart-breaking inspection, and at the time a Meerut butcher came up and offered me Rs. 3-8 all over. I selected 50 wethers and sold the remainder at Rs. 3-12 all over including lambs at foot. In the many changes since I have lost sight of my accounts, but suffice it to say that the young bulls and sheep fleeces more than paid for the cost of cows and sheep including mutton for table for a family of six or seven. I have no hesitation in saying that any old pensioner with a family could not turn his hand to a better use, or make better provision for his family had he sufficient to start him on a sound pasture. He must have had some knowledge of cattle and sheep in his pro-army days, and be independent of his shepherd or native superstition, and keep his weather eye open.

We learn from one of our English exchanges that Professor Brown read an interesting and instructive paper, on 'Food in Cattle Life' at a recent meeting of farmers in Canada. Previous to reading his paper, Mr. Brown distributed cards to the farmers present, giving the following statement of the result of nine years' feeding with store steers at the Ontario Experimental Farm:—

	Daily Increase per head	Cost per lb. of added weight.
1. Permanent pasture	2 05	2
2. Hay pasture	1 15	5
3. Mixture of corn, peas, oats and barley, with hay and bran	2 25	8½
4. Cooked hay, roots, and bran, with mixture of grain uncooked	1 30	9
5. Hay, roots, and bran, without grain	2 14	9
6. Corn, with hay, roots, and bran	2 00	9½
7. Peas, with hay, root, and bran	1 91	9½
8. Uncooked hay, roots, and bran, with mixture of grain	2 60	9½
9. Oats, with hay, roots, and bran	1 64	10
10. Mangolds, with hay, and mixture of grain	2 38	10½
11. Turnips, with hay and mixture of grain	2 30	10½
12. Cut hay and roots, with bran and corn	2 10	11 9
13. Mixture of grain, with oil-cake, hay, roots, and bran	2 00	11½
14. Mixture of grain, with 'Thorley,' hay, roots, and bran	2 40	11½
15. Barley (black), with hay, roots, and bran	1 60	11½
16. Barley (common), with hay, roots, and bran	2 02	12
17. Rice meal, with hay, roots, and bran	1 81	12
18. Sugar beets, with hay and mixture of grain	2 70	12½
19. Wheat damaged, and valued at 60 cents per bushel, with hay, roots, and bran	2 00	12½
20. Uncut hay and root, with bran and corn	1 78	14
	2 02	19

Commenting on the table given above, Professor Brown said it was likely that no similar statement in variety and possibly of such practical value had ever been issued from one place before. All the conditions were as uniform and alike as could possibly be secured in conducting the experiments, so that nothing influenced the results excepting food. During the reading of his paper, Professor Brown drew a number of these present into discussion on the subject dealt with by his paper, and in this way he was enabled, by simply answering questions, to impart a great deal of useful and valuable information. In concluding, said Professor Brown, 'it may be asked, what then is the practical value of all these experiments? I would answer that my lesson from these experiments is that there is value in variety.'

THE USES OF COTTON-SEED.

To the average Indian reader the heading of this paper will, we fancy, scarcely be intelligible. To what other uses can cotton-seed be put, beyond that of sowing for the purpose of raising the cotton plant, which in its turn will yield the cotton of commerce? The answer will, in all likelihood, be "why, none, to be sure! Never heard that it had any other uses." And yet, our 'go-ahead' cousins across the Atlantic have found innumerable uses for an article which, not many years ago, formed the subject of much speculation as to how it was to be got rid of, and which was regarded as an unmitigated nuisance. Our information on the subject was necessarily limited; for we do not remember to have heard of, or read anywhere, anything concerning the uses of cotton seed. We were aware personally that in some parts of India the seed is sometimes used to feed goats with, and that it occasionally forms part of the buffalo's food. But we are not aware that the seed is put to any other uses in India. The following, which we take from the *Gardener's Chronicle* of the 26th ultimo, will give some idea of the uses of cotton-seed in America:—

"It is well-known that cotton-seed is, as an article of commerce, a comparatively modern introduction. Not many years since the seed, which was produced in such abundance in the cotton plantations of America was, not only a waste product, but one which the growers scarcely knew what to do with. Of late years the oil has been expressed in continually increasing quantities, and applied to a variety of useful purposes, not the least important of which is its substitution for olive oil, for cotton-seed is now purified so carefully that the result is a clear, bright, limpid oil, equal in appearance, if not in taste, to the best oil obtained from olives. Mills for the expression of cotton-seed oil have been erected in America in increasing numbers of late years. In 1870 there were only 26 mills, and in 1880, 47, six of them in New Orleans. At the present time these mills are scattered throughout the South in all the important cotton centres on the rivers and on the railways, and number 108 in all. The average yield of seed is about 3½ lbs. to every lb. of lint. The amount of seed annually crushed in the United States averages about 420,000 tons. A ton of cotton-seed yields 35 gallons of crude oil, 28 lbs. of cotton, 750 lbs. of cake of average value of 19 dollars, making the total value of the cotton-seed product of the South 8,000,000 dollars, or 3 per cent of that of the cotton crop. Cotton-seed cake—the residue of the seed after the expression of the oil—is used chiefly for stock feeding and fertilizing purposes; it is generally ground into a meal known as cotton-seed meal. Most of that used for feeding purposes is shipped to this country, where it is extensively used for fattening stock. It is also said to be a splendid food for cows, causing a rich and plentiful flow of milk. The cake is shipped from America in sacks containing 200 lbs. each; it is of a rich golden colour when fresh, and has a sweet, nutty, oleaginous taste. It is a very valuable fertilizer for a large number of plants. The oil from cotton-seed has been applied to a variety of uses in America, such as the manufacture of the finer kinds of soap; also for mixing with paint, and for lubricating purposes; it, however, dries too slowly to be valuable for the first purpose, and is too greasy or sticky for the second. Another product is glycerine, but this manufacture has been but little attended to as yet. One

gallon of crude oil will make 3½ lbs. of glycerine. Its chief use, as before stated, is as a substitute for olive oil, and the following extract will show the state of perfection in which the oil is now prepared:—It is nearly impossible to detect good cotton-seed oil from the best brands of olive oil by taste, smell, or any other process; this the olive growers of Italy have been unwillingly compelled to acknowledge. An instrument called the oleometer has been invented to distinguish between the two oils by means of their different specific gravity; but this is confessedly an uncertain and unreliable test. The hulls or shells of the seed are used as fuel to drive the oil-expressing machinery; and containing some oil, they burn well and produce a good heat, and are used exclusively with the same effect. It was recently stated in America that before long cotton-seed would yield all the grape-sugar demanded by the commerce of the world. It is estimated that, if all the seed produced was used and crushed, this little article, once despised and deemed of no value, would be worth between 80,000,000 and 100,000,000 dollars annually."

Here is surely a large field for India to enter into competition with America. After a perusal of the foregoing, our Indian economists will perhaps turn their attention to a hitherto undeveloped industry. From the last Annual Statement of the Trade and Navigation of British India (1884-85), we find that the total exports of cotton amounted to 5,066,057 cwt., or 253,302 tons, valued at Rs. 13,28,63,873. Of this the several Presidencies gave the following figures:—

	Cwts.	Value in Rs.
Bengal	283,976	68,82,004
Bombay	4,084,609	10,88,52,143
Sind	71,860	17,45,986
Madras	557,877	1,34,72,806
British Burmah	82,035	19,10,074

From the Monograph on cotton cultivation in the Punjab, recently issued, it appears that 84 per cent of the whole yield of the province is locally consumed. Taking this as a basis for calculation, we arrive at the conclusion that the quantity of cotton exported only averages 16 per cent of the total yield of the entire peninsula, including British Burmah. Assuming therefore that 84 per cent of the seed yielded is retained for local consumption, and taking the calculation given in the Monograph referred to above, that the proportion of seed to cotton is two-thirds, we have for disposal 506,604 tons of cotton-seed. The quantity of seed annually crushed in the United States averages about 420,000 tons, which yields a revenue of 8,000,000 dollars, or 3 per cent of the cotton crop. Therefore 506,604 tons of seed would represent 9,649,600 dollars, or, reckoning at the rate of Rs. 2-8 to the dollar, we should have a revenue from cotton-seed alone of Rs. 2,41,23,800, which at present is entirely lost to the country. In making these calculations, we have taken only 16 per cent of the yield of the country, taking the yield and consumption in the Punjab as a basis for the whole of India. It may, however, be stated, without fear of being contradicted, that this represents a very small proportion; as it is not to be supposed that 84 per cent of the seed is actually retained for local consumption and sowing. Our estimate may therefore be regarded as very low.

In no trade returns of India have we come across cotton-seed as forming an item of export or import, nor have we seen any allusion to it as an article of commerce. In the Punjab cotton Monograph referred to in this paper, it is stated that the labourer employed to separate the cotton from the seed, "is commonly paid by receiving the cotton-seed which he extracts," and the only use to which the seed is put would appear to be the feeding of goats and buffaloes, and this, so far as we are aware, only to a limited extent. We have sometimes seen the seed used for illumination purposes. Earthen pans, 4 to 6 inches in diameter, are filled with the seed; the common "sweet" oil is poured over it, and the whole is, burns with a fitful sort of blaze for a couple of hours or so.

That cotton-seed opens a wide field for the development of a profitable industry in India must be admitted. It is therefore to the owners of oil-presses and capitalists in particular that we address ourselves. We see no reason why it should not prove as profitable in India as it has in America. The Gov-

ernment of India have turned their attention to the development of various industries in this country—silk, wheat, cotton, ensilage, &c. We hope they will add another to the list—the extended use of cotton-seed.

CATTLE, HORSE, AND AGRICULTURAL EXHIBITION AHMEDNUGGER.

WE have received a prospectus of the cattle and horse and Agricultural Exhibition, and a plough match, to be held at Ahmednugger on the 17th November 1885, when it is expected that about Rs. 3,000 will be distributed in prizes. It is noticeable that prizes will only be awarded to exhibitors who live in the Ahmednugger district. Horses which have been formerly shown at the Sarun show will be allowed to compete for the prizes allotted to horses. The following rules have been published for the information of intending exhibitors:—

Any taluka which gains a general prize in any class will not be eligible for a taluka prize in the same class.

Two prizes will not be given for the same animal or product.

Exhibitors of grain, seeds, pulses, cotton, fibres, tobacco and jagri must exhibit the minimum quantities stated in the prize list, and their exhibits must be placed in the exhibition room by 12 A.M. on the 16th November. Horses and cattle must also be in the yard by 12 A.M. on the 16th November. They will not be received after that hour.

Perishable articles, such as vegetables and fruits, will be received up to 9 A.M. on the 17th November.

Batta to exhibitors from the Ahmednugger district will be given under instructions to be issued to the several Mamlatdars.

The beasts will be fed at the expense of the fund during the time required for the exhibition.

The judges will decide on the merits of the exhibits in the afternoon of the 16th and the morning of the 17th November.

The show will open at 4 P.M. on the 17th November, and will remain open until the evening of the 19th November.

On the first day admission to the exhibition will be allowed to all subscribers and to their friends. No gate-money will be taken.

On the second and third days, the show will be open to the public free of charge.

The prizes will be awarded on the 19th November, after which the show will be closed.

The plough match will commence at 4 P.M. on 18th November; entries for the match will be made on the previous day.

The following prizes are offered, but prizes will not be awarded if the committee consider that the exhibits are not satisfactory, or if there be not a sufficient number of entries for competition.

The committee will be glad to receive and allot space for any new country-made machinery and implements, and will grant certificates or award prizes for them not exceeding 50 Rupees in all.

There are 12 classes in the horse and mule section, with prizes aggregating Rs. 1,245; twenty-one classes for cattle, including sheep and goats, with prizes aggregating Rs. 1,177; under grain 15 kinds are mentioned, for which Rs. 235 are to be given in prizes, with twelve kinds of pulse, having Rs. 79 for prizes. There are nine species of oilseeds mentioned, having an allotment of Rs. 72 for prizes. Vegetables include the largest number of species, there being no less than 36 varieties. Betel-leaves, turmeric and tamarind fruit come under this head, for which Rs. 127-8 are set apart for prizes. Under fruit 22 species are named. "Green eatable Indian corn" is included among 'fruit.' This is the first time we have heard of Indian corn being classed as 'fruit,' but "circumstances alter cases," and those of Ahmednugger are, perhaps peculiar. Rs. 132-8 are to be awarded in prizes under this head. Then comes the "Miscellaneous" head, which includes sugarcane, coarse sugar, tobacco, cotton, cleaned and uncleaned ambadi [we don't know what this represents; the English equivalent might have been given] tag-hemp, aloes-fibre, wool, isserne-seed, guinea-grass, and lucern-grass, for which Rs. 834 are to be distributed in prizes. Last of all come the plough matches—there are to be two. The first match is open to all; any plough may be used, and any breed of bullocks. There are two prizes for this—Rs. 30 and 10. The other match is open only to the students of the agricultural class, Ahmednugger. The conditions are the same, except that not less than six are to start. There are four prizes, Rs. 10, 8, 6 and 4.

There cannot be any doubt that exhibitions of this class exercise an important influence in improving the agricultural condition of the people of the district where they are held. The value of exhibitions, no matter of what class, has been acknowledged by competent authorities, and we should like to see more attention paid to the inauguration of agricultural shows. There are too few of them, and at intervals too far apart. Glancing through one of our English exchanges, we find reports of no less than seven agricultural shows in one week. The advanced state of agriculture in England and America, and the great superiority of the cattle and sheep in those countries, are due entirely to competition. It is only by encouraging competition that we can hope to do any good towards the development of the resources of this country, especially in the direction of agriculture and live-stock.

Miscellaneous Items.

Four students of the Agricultural College of Madras, who have received scholarships from the Mysore State, having completed their course, have proceeded to Mysore to see the Dewan regarding the inspectorships which have been guaranteed to them.

CHOLERA is prevalent in parts of thirteen districts of the Bombay Presidency. The only districts, however, in which the disease is present in a severe form, are Satara, where there were 251 attacks and 91 deaths during the past week; Poona, where there were 196 attacks and 141 deaths; and Nasik, where there were 54 attacks and 28 deaths.

We are pleased to read of the efforts of Mr. Ozanne, the Director of Agriculture, in connection with the thrashing of Indian wheat by means of steam power. The trial recently made with a steam thrasher at Nasik is regarded by the native agriculturists, so very conservative in all that relates to the tilling and improving of the soil, as "fairly successful."

THE other day eight Australian rams were sent ashore from the steamer *Nevan* from Calcutta, and were forwarded by rail to Bangalore to Mr. L. Bickette, Deputy Commissioner. The above lot formed part of a consignment of thirteen rams, which had been shipped in Australia for Madras via Calcutta for the Maharaja of Mysore, five having died on the voyage.

THE continued fall in the rupee is engaging the earnest attention of business men in Ceylon, but not to the same extent as in India. In Ceylon the largest class—the planting community—are directly benefitted by the fall of exchange, at least all who are proprietors, and this accounts in great measure for the comparative equanimity with which the public here seem to regard the existing state of things, compared to the more disturbed condition of the Anglo-Indian community.

MR. PENNABURY, the Traffic Manager of his Highness the Nizam's Guaranteed State Railway, has issued notices in English and the vernacular, informing native merchants and other gentlemen interested that he will be glad to see them at any time, either at his office or his bungalow, to discuss with them such measures as would, in their opinion, be likely to increase the traffic or improve the present system of working. The Traffic Manager has also invited any merchant having any grievance to complain of concerning the Railway to confer with him in regard thereto, and he promises to do all in his power to find a remedy.

A MADRAS contemporary says:—We believe Mr. McDonald of the Excise Department has gone in for brewing on a small scale, and has sent the result of his labours, in the shape of bottled beer, to the Civil and Military Club. Whether it is owing to vitiated taste or not we don't know, but the ale did not "take" with the frequenters of that institution. One of the frequenters, however, we are told, gave the liquor a trial, probably with the Bajan-inspired object of encouraging local trade, with the result of his abjuring the use of excisable liquor altogether since. This is certainly better than the "Nile Rum" of which so much was recently said, and Temperance establishments would do well to procure a supply of this social poison, as a remedy for the evil against which they are so strenuously fighting.

THE toddy question, it appears, has again been mooted in Surat. The Imperious Collector who wrought so much woe on the people of Tanna, and who is popularly reported to be the chief author of the harsh Forest and Abkari rules, is now transferred to Surat.

MAJOR BOWEN, R.E., the Acting Chief Engineer of the Mysore Government, has completed his tour of inspection in northern Kolar, and has ascertained that prospects have continued to improve, and that the crops are flourishing. In some localities, as in eastern Kolar, and on the eastern side of the road from Channarayana to Beggepally the prospects are still rather gloomy, and he has had a few tentative public works opened. He has been led to the conclusion that unless the north-east monsoon fails there is now no serious cause for anxiety. Good rain is reported from Chital droog, and all is considered safe in that district. Bangalore also during last week, and now presents as verdant an appearance as Madras.

THE Madras Government having reason to believe that it would be a convenience to some members of the planting community in Southern India who desire to send cinchona exhibits to the London Exhibition, if, instead of being obliged to send such private exhibits on their own account through Messrs. King and Co., they could send them as part of the Madras Government collection now in course of preparation, the Director of Government Cinchona Plantations was requested to report whether there is any practical difficulty in the way of such an arrangement. Mr. M. A. Lawson replied that he did not "see that there can be any difficulty in arranging with private contributors to the London Exhibition that they should send their exhibits through this department."

IT is pleasant to find the effects of last spring's good harvest already appearing in the export trade of the N.-W. Provinces. The returns of railway-borne traffic for the quarter that goes up to the end of June exhibit this year a noticeable advance upon those of 1884. Of wheat alone 25 lakhs of maunds have been sent away, against some 14 lakhs last year, the average export of the quarter for the past few years having been about 16 lakhs. Onda and Rohilkund have done the largest business in wheat, as also in linseed, the exports of which have almost trebled, thanks to the bumper crop that was gathered east of the Ganges. The increased export both of wheat and linseed has gone chiefly to Calcutta. Meanwhile people who look closely into trade will be gratified to see that six new "blocks" have been added to the return for defining with more precision the destination of the produce of the provinces. With two of these, Mysore and Hyderabad, no business is done at all. Madras and the Berars take a percentage of less than unit, and Sind, which was formerly lumped in promiscuously with the Punjab, takes 1.5. The additions are, therefore, chiefly valuable as an illustration of the perpetual tendency of Government work to become more and more complicated, though in this instance they have been made in order to harmonise with the returns of other provinces.

A SPECIAL meeting of the shareholders in the Australian Frozen Meat Export Company, Limited, was held at the office on the 8th September last, "to consider the fall in the price of the meat in England, and its effect on the operations of the Company." Sir James McCulloch presided. The Company has overdrawn its account with the National Bank to the extent of £11,500, on which 8 per cent interest is being paid, and if the business were suspended, the Orient Company would be entitled to claim £4,700 for non-fulfilment of the contract for the conveyance of the meat. Owing to the fall in the price of meat in the London market, the margin of profit had given place to a loss, but the Orient Company have virtually undertaken to carry the meat for 9d. per lb. (in stead of 1½d. as at present) so long as the price obtained does not exceed 4d., and any balance above that is to be divided equally between the Orient Company and the Frozen Meat Company. It is believed that under this arrangement the business can be carried on without loss. The directors were authorised to continue operations until the end of the year, and in the meantime an effort is to be made to induce stock-owners to guarantee consignments of meat on their own account afterwards, so that the Company may continue its operations to freezing. The chairman urged that, in view of the falling price of wool, the squatters and stockowners of Australia should combine, and send a thoroughly qualified representative to China and Japan to endeavour to open up markets there for wool with wool from these colonies.

Selections.

STOCK FARMING IN INDIA.

(Continued from last week.)

THIS farm, which comprises 37,051 acres of grass land, is situated east of Delhi and Karnal, and about the same distance, 100 miles, from either, being now accessible from Delhi by the Rawari and Ferozepore railway. It was used by Government for stud and cattle breeding purposes as far back as 1845. From 1854 to 1875 it was under charge of the Stud Department. But for the last 8 years it has been used as a cattle breeding establishment worked by the Commissariat Department. I first made acquaintance with the place in 1897 during the mutiny, when I accompanied a column under General Van Cortlandt, C. B., in its march from Ferozepore to Delhi through Hissar. Within a year after that time, I joined the Commissariat Department, and was stationed at Delhi, where I had an opportunity of realizing the good work of this farm in breeding bulls for the improvement of the cattle in the neighbouring districts, as well as in those more remote, for I was required to purchase some 1,200 bullocks for siege train purposes, and these I most readily obtained of the standard height of 52 inches and prescribed age of 5 years, the entire stock exhibiting very clearly the strain of the Hissar blood. Three years ago I was called upon to make a special inspection of the Hissar Farm, with the economy of which Government was greatly dissatisfied, the expenditure being very enormously in excess of the income. I found the main reasons for this to be: 1st, that sufficient stocks of dry fodder were not kept in hand to supplement grazing and to guard against fodder famines, which were said to recur every three years; and 2nd, that the cattle, some 7,000 heads, consisting for the most part of very fine and well-bred animals, were kept in a semi-wild state in very large herds, sufficient attention not being paid to weeding the stock and segregating the cows when in calf. The results of this last evil and of fodder famines during which enormous losses of stock used to occur, and the cattle become unfruitful being that the average birth of calves fell as low as one in three years per cow, and that the cost of the bullocks raised on the farm for Artillery purposes was enormous. Government sanctioned then the inauguration of a change of system under which the farm should be sufficiently stocked with fodder, to go through two consecutive years of fodder famine, and the cattle divided into small lots with a larger proportion of attendants, and I am very pleased to be able to say that, thanks to the intelligence and energy of the Superintendent, Captain Marrett, the farm is now amply stored with fodder, and the average birth of calves has been raised to 75 per cent per annum, i.e., one per cow in eighteen months, with every prospect of farther great improvement. In storing the farm with fodder, the drain upon the supply in the daily consumption has been very materially lessened by resort having been made to "ensilage," some 12,000 maunds of which were for the first time stored last year, and have since been fed off to the cattle. Regarding this matter I will now read you a short paper by Captain Marrett, the Superintendent of the Farm.

Notes on Ensilage at Hissar, during 1884-85.

For the first time the experiment of storing fodder by siloing it was tried at the Hissar Farm during the past year.

The fodder so preserved was of three varieties:—

- (1) The coarse grass that had grown up during the rains in the incense gardens.
- (2) The finer grasses obtained from the Bhir or cattle pastures.
- (3) Green Jowar or cherry.

The results obtained fulfilled our most sanguine expectations, as the fodder, when taken out of the pits, was found in good preservation, and was readily eaten by cattle both young and old.

(2.) Most of the pits consisted of holes dug in the ground 30' long by 10' broad by 2' deep, and a ramp or slope at one end to enable bullocks to walk down the pit was made slightly narrower at the bottom in order to obtain a wedge shape, and with a view to better compressing the grass; but pits with straight sides proved equally successful, provided sufficient care was exercised at the time of charging them to have the grass well trodden down.

(3.) The fodder, as it was cut, was brought to the pit and evenly laid by 5 men at the bottom to a height of about a foot, when a pair of heavy bullocks was admitted by means of the ramp, and allowed to walk about until this layer was pretty well consolidated; the same course was persevered with till the fodder was

carried to about 6 inches above the ground level of the pit; this was done to allow for the fodder sinking on the earth being heaped upon it. The only pressure and covering the fodder received was that obtained by the earth excavated from the pit. The time usually taken to fill a pit of the above dimensions was about 12 hours, and the contents averaged from 500 to 600 maunds.

(4.) On opening these pits between 5 and 7 months afterwards, the grass was found to have sunk about a foot below the surface of the ground, and the fodder to be of a deep brown colour, full of sap, and emitting a strong pungent smell, though this did not prevent animals to whom it was offered on the spot eating it readily.

(5.) The total quantity of fodder siloed in the farm was about 12,000 maunds, and as this was only gradually expended, some pits were not opened till after 9 months, and it was found in these cases that the smell was perceptibly less; in fact there was little or no smell, and this was the more apparent in pits that had been charged with the fine grasses obtained from the Bhira.

(6.) Having noticed the fact, and with a view to still further testing the point, I had one pit charged with coarse grasses obtained from the sides of a water-course, the grass was in seed at the time, and after a lapse of 5 months we opened it and found that the grass was of a very dark colour indeed, while the stench arising from it can only be compared to rotten fish: it is needless to say that no cattle would eat it.

(7.) The experiment of leaving the fodder in the pits for 12 months is now being tried, and the result will be duly reported.

(8.) The cost of preserving fodder in this manner has been about 14 maunds per rupee. The digging of the pits was, of course a heavy item, and the fact of having many of these ready made will considerably affect the price of our ensilage this year.

(9.) The loss of weight in the fodder, at present ascertained, has been about 25 per cent, which added to the cost of storage makes the price 11 maunds per rupee.

Many of you must have had your olfactory nerves most painfully assailed by the crude efforts being made at many stations to utilize this fodder when immature, and you will halt with satisfaction the fact which this paper discloses, that, if the fodder is kept until it is mature, the truly awful smell which proceeds from it when it has only undergone a third or only half the period necessary to render it fit for use, is avoided. The advantage of this system under which rank and immature grasses and crops can be stored and converted into highly nourishing fodder is incalculable to an establishment like that at Hissar. The fodder famines to which I have alluded are not, by any means, of necessity, the result of total failure of the monsoon. There may be a good rainfall from 15th June to 10th August; but if it ceases then, and dry hot weather sets in and continues for a month, you may say good-bye to the hay crop, and anticipate scarcity of food grains also from complete failure of the rabi crop. But under the system of ensilage, the vegetation which springs immediately in the commencement of the monsoon, would, in such a season as that I have described, admit of any quantity of fodder being siloed during July. In fact, I consider that the farm at Hissar may, by resorting to this means, go through three or four consecutive bad years unhurt. The success which had attended the distribution of farm bred bulls, has not attended that of the fine rams raised at Hissar. The reason of this is that the villagers have hitherto obstinately closed their eyes to the necessity of preserving fodder to supplement grazing. They shake their heads when you send them a good half English bred ram, and say "how could that animal find food for himself around our villages?"

They purposely raise the miserable creatures they call sheep, because these animals do, though how they do, it is a marvel to me, manage to get through the year with little or no addition to the scanty grazing they pick up round the villages. If there was any foundation for the unsophisticated townsman's idea that "strenky bacon" was produced by an alternate process of high feeding and starvation, these unfortunate sheep, which for a short season during the monsoon are, so to say, in clover, would turn out highly variegated mutton. But the stuff they do produce is like themselves, the poorest of the poor. We have now enlarged our sheep-breeding operations at Hissar in view to contributing in a small way to the mutton supply for the troops at the nearest large stations, and I hope to demonstrate very soon that it pays to raise good heavy sheep by affording them good grazing and supplementing it by stall feeding; and I am very confident that the improvement in wool, both in outturn and quality, by crossing the country sheep with good English and Australian stock, will go far to ensure the commercial success of the venture. I have here some samples of wool from the Hissar

Farm, which some of you may care to look at presently. They are specimens of the wool of the imported Australian south-downs, of several of the pure country breeds, and of various crosses with English stock, and it does not require an educated eye to distinguish the great improvement in the wool of the cross breeds compared with that of the indigenous stock. I may mention that our mixed wool at Hissar, disposed of on the spot, realises a very satisfactory increase in price on the country produce. The Superintendent is now making efforts to put his wool into the export market, and I anticipate that, with due attention to the subject, we shall obtain very satisfactory results, the industry being as yet in its infancy with us. The large quantities of natural grass which are allowed annually after every monsoon to dry up and wither in thinly populated tracts of country, and the large quantities of hay annually sacrificed in the well populated districts, by indiscriminate grazing and the non-reservation of meadow land in its due season for hay purposes, represent so much hard cash allowed to melt away every year, and a proportionate loss of revenue to the State, while the scandal, still to a great extent perpetuated, in the exercise directly or indirectly of a sort of prescriptive right to cut grass where we choose, is, in my humble opinion, a great reproach to us, and I think that it is very evident that rigid enforcement of the laws affecting trespass is called for.

I have little doubt that not only in the vicinity of our cantonments but all over the country, if proper protection existed, the cultivation of hay, which is unattended with the risk attached to the cultivation of grain crops in loss of money laid out in ploughing, seed, &c., by failure in the rainfall, would quickly be recognised by the proprietors as so lucrative as to justify a due proportion of their land being reserved as meadow land, but what would be the result with land so set apart as matters now stand? I certainly would not be inclined to purchase the embryo hay crop under the supposition that it was in the power of the owner, with all the good will in the world, to protect it for me.

As I have before remarked, I have no doubt that in a very few years, if we now do our duty, our markets will be well stocked with good hay. But we must face the fact that our dearly beloved grass-cutter with his *coorpa*, and his proverbial excess of olive branches, will disappear from the scene. Personally, I should rejoice in being thus released of several of the numerous domesticities I am now forced to maintain, and professionally I have no dread of inconvenience to the service resulting from the grass-cutter being a thing of the past, either in regard to cantonment life or to service beyond our frontiers, in reference to which last, no doubt, necessity will as usual prove to be the mother of invention, and we shall manage as other nations do when they start on the war-path. If the independent princes and chiefs of India can only be got to devote attention to this subject of "Stock farming as connected with hay and other fodder farming," what an addition to their revenue they will make. Take for instance his Highness the Maharaja Holadia of Gwalior, in whose country uncultivated land certainly predominates. This land may not, it is true, be capable of the irrigation necessary to grain cultivation, but that is no reason why the revenue from it should be largely confined to charcoal obtained from the stunted jungle, while every year a luxuriant crop of good hay is produced out of it, which if cut in its season would support stock farms for rearing horses, mules, cattle, and sheep. I have some experience of hay making in that country, and I am sure that the farmers could stack it on the spot at 12 or 14 annas per rupee, at which rate, as regards cattle and horses, a daily ration of 8 seers per animal, which, (allowing for grazing, would be heavy) would cost, per head all round, from 5 to 6 rupees per annum.—*Englishman*.

TUBERCULOSIS.

THE evidence from which it must be decided whether or not tuberculosis of the lower animals is identical with the disease of the same name in man is, as with the question already discussed, partly clinical and partly experimental.

It is to be noted at the outset that the appearance of the diseased parts in man and animals are so similar, that for a very long time the same terms, such as *consumption*, *cavities*, &c., have been applied to distinguish both conditions. Nevertheless, the morbid anatomy of the tubercular growths in some, at least, of the inferior animals, is not strictly identical with that of the same growths in man; but the differences are unimportant, and not greater than in other cases (such as splenic apoplexy of cattle and human carbuncle), where there is no doubt that we have only one and the same affection to deal with.

Cases of natural transmission of tuberculosis from animals to man are, from the nature of things, very difficult to prove. As an example, the following two cases may be cited. Dr. Bang, of the Royal Veterinary School, Copenhagen, mentions in a learned article on tuberculosis in the udder of the cow, a case where a lady, who had been previously considered healthy, suddenly developed phthisis, and died within a year. During the early stage of her disease she gave birth to a child, which became tuberculous, and died within six months. It was found that one of the cows supplying the household milk had tuberculosis of the udder. Dr. Stang, of Amborsob, has recorded a case, in which a boy, previously healthy, and born of healthy parents, without any history of tubercle on either side, developed an acute attack of tuberculosis, and died after an illness of four weeks. It subsequently transpired that the boy had for a long time been drinking milk from a tuberculous cow. Many similar cases might be cited. These, however, may suffice as a sample of what, it must be conceded, furnishes strong presumptive evidence that animal tuberculosis is transmissible to man—that in fact, the two diseases are identical.

It will readily be understood that even if the diseases are the same, cases of transmission from man to animals are likely to be extremely rare, and that when they do occur they are very likely to escape observation. Passing over this then, we come to the evidence afforded by experiment, of which there is no lack. It has been abundantly proved by numerous observers that the sputum expectorated by consumptive people, and tubercular matter taken from the bodies of such persons after death, possess the power of setting up tuberculosis in animals almost with certainty, when injected under the skin and in a large proportion of cases when introduced into the stomach with food, or when dried and disseminated in the air, that the animals are compelled to inhale. Tuberculosis so set up differs in no respect from tuberculosis naturally contracted. It is hardly necessary to say that there can be no experimental evidence proving the transmissibility of tuberculosis from animals to man, but without this, it must be admitted that there is complete proof of the identity of human and animal tuberculosis.

In 1881, Koch, the illustrious German, who has done so much to further our knowledge of the cause of infective diseases, showed that tuberculous matter, whether taken from man or animals, contain peculiar minute organisms, or bacilli. By elaborate experiments he was able to isolate these organisms, and to cultivate them in artificial substances. With minute quantities of a pure cultivation of this nature, Koch was able to produce tuberculosis in many different species of animals, and the result he found was always the same, whether the original material was derived from man or animals. Koch therefore concluded that he had discovered in this minute organism the cause of tuberculosis, and the explanation of its contagious and transmissible character. At first his statements and conclusions were received in many quarters with scepticism; but as the result of confirmatory investigations by a great many eminent authorities, it is now all but universally believed that Koch's bacillus is the actual cause of tuberculosis.

The bacillus of tuberculosis is a minute organism, having the form of a short rod, sometimes beaded, and at other times plain. It multiplies by growing in length, and then dividing across, and also by the formation of spores. These spores appear in the rod as minute bright specks, and when the rod breaks up, the spores grow into new rods. The rods are killed with comparative ease by boiling, &c., but the spores are killed with great difficulty. The bacillus belongs to the same family of living things as the organism which is the cause of swine fever, and that which is the cause of splenic apoplexy. It has, however, some peculiar characters, which go far to explain some important points in the pathology of tuberculosis. One of these—and it is one of great importance—is the fact that the bacillus of tuberculosis is incapable of multiplying outside the animal body, except at temperatures approaching blood heat. Another peculiarity is, that the growth and multiplication of the bacillus, even when kept at the most favourable temperature, take place very slowly when compared with the rate of growth of other disease organisms. These peculiarities of the tubercle bacillus appear to afford an explanation of why tuberculosis, although contagious, is much less common, for example, glanders or pleuro-pneumonia; and they also serve to explain the slow rate at which the disease develops in the human body.

It has for a long time been known that some human beings and some animals, there is a strong hereditary tendency to tuberculosis, and also that such predisposed individuals have certain peculiarities of shape and build, that mark them out to even

ordinary observers. It seems possible to explain the hereditary tendencies of the disease in two ways. In the first place, it is beyond doubt, that the tubercle bacillus itself may pass from the mother to the offspring, which may thus be the subject of tuberculosis at birth; and in some cases, what passes for hereditary tendency is not a mere tendency, but a manifestation of the actual disease. In the second place, it would appear that there is a kind of consumptive constitution, the possessors of which are peculiarly liable to contract tuberculosis, where other individuals would resist the onset of the disease. And it is not far fetched to suppose, that beneath the obvious peculiarity of a consumptive build, there are in the fluids and tissues of those predisposed to consumption, certain special characters, beyond the reach of chemical or physiological research, that render these fluids and tissues a more favourable soil for the growth and development of the tubercle bacillus. As bearing on this point, it may be mentioned that Koch has shown that a particular bacillus invariably causes blood-poisoning when inoculated into ordinary house mice, but that it is quite harmless to field mice.

There has now been passed in review as much of the history of tuberculosis as may enable one to form an opinion on the following all important questions:—1st. Is it in the interests of the stock owner and of the community that tuberculosis should be made subject to the regulations that apply to the diseases already embraced within the Contagious Diseases (Animals) Act? 2nd. Can the flesh or milk of tuberculous animals be used as articles of food without risk to the consumer.

To the first question, we think that the evidence directs an affirmative reply. In the interest of the stock owner, and in the interest of the community, who are benefited by all that fosters the well-being of the food supplying animals of the country, it is desirable that every tuberculous animal should be slaughtered, adequate compensation being, of course, awarded to the owner. In this connection the curability of the disease hardly needs to be discussed. All authorities are agreed that we know of no cure. It is not denied that recoveries do take place; but they are extremely rare—more rare, without doubt, than in cattle plague or pleuro-pneumonia. And then it must not be forgotten that as long as a tuberculous animal lives, it is a menace to its neighbours, since it is surely though unobtrusively disseminating the living virus of the disease.

To the second question all the evidence proclaims an unhesitating No. There must be no half measures. It is not a question of how much of the carcass of a tuberculous animal is hurtful. In acute tuberculosis it has now been proved that the blood, and therefore the entire animal, contains the organism poison—the bacillus. Nor let it be supposed that cooking can be relied on to destroy this poison. Animals have been experimentally fed on roasted tuberculous flesh, with the result that they soon became the subjects of the disease. The same arguments apply to the consumption of milk from tuberculous cows. The milk of such an animal may not always contain the poison, and even when it does, it may not contain it in sufficient quantity to affect a robust person. But that has no bearing on the question. It is enough to know that such milk very frequently does contain the poison; and that it can never be pronounced free from danger, even when its characters are apparently quite normal. There must always be a risk of setting up in the body of some of its consumers a most incurable malady: from this risk the public should be protected.—Var. Ed.—*North British Agriculturist*.

TUBERCULOSIS IN CATTLE.

Sir,—There are a few remarks in the letter of 'J H.' published in your last issue on the above subject, which I can scarcely allow to pass unmentioned. In view, however, of the able article on tuberculosis in the same issue by your Veterinary Editor, an extended notice thereof is rendered unnecessary. Without referring to the possible underlying remarks in the first two or three paragraphs of your correspondent's address, and shall continue to advise that all tuberculous animals be slaughtered, and their carcasses destroyed; in other words, the destruction of diseased animals, and their carcasses is one of the suppressive measures I would have carried out. Putting 'the veiled power of the Divine Flame' aside for the moment, I adhere to the statement made in my last, as to the curability of tuberculosis, and further say that neither 'J H.' nor any other living man can bring forward proof that an animal, once the subject of the disease, has been so fortunate as to get rid of the poison thereof from

its system, and become again a thoroughly healthy animal. I cannot see anything like a *flatus* of demerolism in the admission made by me, that the disease sometimes becomes quiescent. Inasmuch as it has been shown over and over again, by direct experiment, that not only fibrous tubercle (grey nodules), but even *absolutely* tubercle (i.e. tuberculous products having undergone calcification), is extremely virulent, when introduced into the system of another animal, either by inoculation or ingestion; and can 'J H.' guarantee that every particle of tuberculous matter will be removed by the butcher from the carcass of a consumptive animal before it is exposed for sale, as food for man? Perhaps he has not seen, as I have, carcasses with tuberculous deposits about them as exposed, and in some cases the flesh prepared for the mincing machine, preparatory to its conversion into sausages or other similar delicacies. Butcher 'J H.' butchers could tell the curious tale of how many meningeal tuberculous, and other deposits they find in and on animals slaughtered for human food. Doubtless they could, but they take good care to conceal these facts, and I would ask 'J H.' how many meningeal growths are detected by the butcher, seeing that the skull is always smashed through, and a part of it removed with the hide, and that this so-called about in the process of dressing? But, putting all this argument aside, the real question to be answered is this:—Would 'J H.' or any one else, knowingly elect to eat flesh from a consumptive animal? or, if his taste is so depraved, would he if he had the carcass of such an animal for sale, ticket it as the flesh of a consumptive animal?

'J H.' questions the infective nature of the disease. Was he acquainted with the late Mr. Dowar of Midmar? If so, he may know that that gentleman placed on record during his life several positive facts in proof of this, and similar facts have also been recorded by Grad, and a host of other veterinarians. In reference to the consumption of milk from tuberculous animals, I envy the composure of your correspondent, but I would be sorry to share his relief. Lastly, it might be beneficial to all concerned, if he would explain the signs, to which he refers, of tubercular liquefaction, and teach us at the same time how we are to detect small tubercles in the glands of the udder.—I am, &c.

OPIMUM VS INDIGO.

ANOTHER and a novel phase of the private enterprise question is likely before long to occupy public attention. In this case Government is not competing with private capital in the same field of industry; but a Government monopoly is colliding with an interest which is entirely in private hands. The cultivation of opium is interfering with the production of indigo, and the question is whether one of these products must go to the wall, or whether there is any way of accommodating the difficulty. Within the past few years, indigo cultivation has spread extensively in all the north Gangetic districts of Behar, where opium has long been a staple crop. The competition for good land has thus become very keen, and consequently the value of land has greatly increased. The pressure of the Behar population on the land, which the last Census Report places at 827'03 per square mile, has also tended to complicate matters. Looking to the limited quantity of good land, and the steady expansion of indigo culture, it is difficult to see how matters can be arranged unless by allowing one crop to trench upon the other. The question of growing the two crops in rotation on the same land is one of great importance, and in the course of a Resolution which is before us, Sir Rivers Thompson makes the following remarks on the practice of sowing indigo on poppy lands:—"The custom of sowing the two crops has prevailed for some time in parts of Saran, Tirhoot, Champaran, and Chupra. Well-to-do and independent ryots, Mr. Kemble states, might and do with advantage so themselves grow both crops. But they have to work hard to prepare their land for indigo after the poppy has been gathered, and they, therefore, seldom or never get a second outcrop from their indigo. When, moreover, the ryots grow indigo directly under advances from the factory, complications are likely to arise if they attempt to cultivate both crops." The opium crop is sown in March, just about the time of the indigo sowing, and therefore the ryot who intends to grow both crops would certainly have to work hard to get his land ready for indigo after the poppy crop was gathered.

This is the *bandi* system, according to which the ryot grows the indigo on his own account, and takes it for sale to the factory, and if this system were more generally adopted, it would probably

lead to an improvement in the relations between the two industries. The Government on behalf of the opium interest, is strongly opposed to the lease or farm system, which prevails to a much larger extent, and by which the indigo planter gets the lease of a village for a certain number of years, and utilizes the best lands for sowing his crop. What is known as the *pathi* rule is greatly in vogue, by which a percentage of about two or three cottas in every bigha of jote is taken from each ryot, and either a deduction in his annual rent is made for this *pathi* land, or a rent is paid to him for it. On behalf of opium, we are reminded that it is the older crop, and that it has usually been cultivated on the best available lands. The Government does not see the right of the young and vigorous rival to push its way at the expense of the earlier occupant of the land. This is looked upon as unjustifiable intrusion, and it is implied in the Government view of the case that the planters are guilty of some indefinable offence in treating the question as a matter of business. It is no doubt unfortunate that the two industries should clash in this way, and the result will be neither favourable to opium alone. But it is preposterous to set up any special claims for the protection of the Government monopoly. The Government in its industrial ventures must be prepared to meet the risks and chances to which all such ventures are exposed, and must be ready to recognise the fact that there is no royal road to success in business. Already there has been a good deal of avoidable interference with private enterprise in various directions. The coal sales of the East Indian Railway, are still attracting attention, and the whole question of jail industries yet remains to be placed on a permanent basis. It is, therefore, to be hoped, that, with all due respect to the exigencies of the opium revenue, the Government will not act in an arbitrary spirit in its dealings with one of the principal independent industries in the country.—*Englishman*.

HOW TO GET THE MOST BUTTER.

There are several things which affect the yield of butter from a cow of any kind. First, the food of a cow affects it; second, the manner of setting the milk chiefly in regard to the time which it requires for the cream to rise; and third, the temperature at which this cream is churned.

It has been shown by many careful experiments, and by the results of long practice, that succulent food helps to produce a large quantity of fat in the milk, and also has such an effect upon the same as to cause the cream to separate more completely from the milk, leaving less fat to be lost in the butter milk. Hence, the use of ensilage, or what is better for most farmers and easier to accomplish, the feeding of roots of an unobjectionable kind, such as mangels or sugar beets in the winter, and the use of some kind of meal, preferably a mixture of corn meal and coarse middlings, with pasture in the summer. In winter, the use of cut hay or fodder, moistened with boiling water, with which the meal is mixed, is better than dry hay or fodder. Further, it has been found, that when the milk of the whole herd has been mixed together, and when the milk has been set for 36 hours, and the cream churned at the end of 24 or 36 hours more, the largest product of butter was obtained. When these periods are shorter or longer, the character of the cream differs, and there is a loss of butter in one or the other of the settings or milk or skimmings of cream. Hence it is most profitable for a dairy to consist of as many cows as will supply cream enough for a churning at one milking, and to churn the cream of one milking by itself. Lastly, the temperature of the churning is of importance, both as to the time of churning and the quality of the butter made. An example from the records of Houghton Farm in regard to this point will be exceedingly instructive, and they fully accord with a great number of tests made by the writer during several years past. At Houghton Farm, when the whole milk of a cow (Clover) was churned at a temperature of 74 degrees, somewhat more than a half of the butter was obtained, while at one time actually less than half of the butter was the result, and it required three and sometimes four churnings to procure all the butter. On the other hand, when the cream was churned at a temperature of sixty-two degrees, all the butter was obtained, or in one case only from one and one-eighth ounces to two and a quarter ounces from about forty pounds of milk remained in the buttermilk, and was procured at a second churning. As double or treble churning is manifestly impracticable in a business dairy, and is troublesome anywhere, it is very important to observe every necessary precaution in regard to the temperature of the churning. In the writer's dairy, the regular winter churning temperature was kept at sixty-two degrees, while the summer temperature was fifty-five

degrees. The temperature at which the milk is set and the cream is kept, should also be uniform so that the character of the cream is always the same. It may be thought that a few degrees in the temperature of the cream is a small matter; but great results depend upon small things in all human affairs, as well as in nature; and if a dairyman would succeed in his business, he must observe carefully all these small things.—*American Agriculturist*.

"THE EXODUS OF BONES."

TO THE EDITOR.

SIR,—The letters from Mr. D. B. Allen and "L. L." which have appeared in your columns on the above subject have no doubt been widely read by numberless persons interested in the agricultural prosperity of India, and many in *England*. I therefore wish to submit a view of the question which has been unannouncedly looked by both the writers in their zeal for the welfare of the country.

The bones exported from the country bear but a small proportion to the supply available,—a supply which has existed for untold years, and which has hitherto, I venture to say, been entirely wasted. For the custom is for dead cattle to be dragged and for drying cattle to be driven to pieces of waste land, perhaps the sandy shore of a river or some corner left uncultivated for the purpose, where their bones remain after the *chamars*, dogs, and vultures have each taken their share. A bone or two may be occasionally dragged into a field, but the effect of such waste and strays can hardly be appreciable. Every village has then its Golgotha, from whence the bone collectors get their supplies; for, considering the price of the article, it would not pay even these men to search from field to field for single fragments. They take from a collection, or leave the trade alone. Under these circumstances the export can have, I submit, no appreciable effect on agriculture. The bones, would, if left, enrich one small piece of ground inordinately, and be of no benefit even to the adjacent lands, much less to the village at large. I conceive this argument is borne out by the fact that the export of bones is a trade of comparatively small extent and of recent development, while the accumulation of bones and their decay and dissolution have been going on for centuries, and yet Mr. Allen points to the want of phosphorus in the soil and alleges the lands are deteriorated,—a want and deterioration for which I think other causes may be found than in the Export Returns.

To attempt to stop a trade which is distinctly a benefit to the English consumer, the exporter, and even the humble collector, for a problematical waking up of the Indian ryot to the advantage of using a material he has neglected for so many hundreds of years, and which has not benefited him in any way, is a strange and barbaric policy to advocate in these days, and surely a misnomer to term Conservative. It might, if the argument were pursued to its logical conclusion, be held right to forbid the export of all cake, as it is a valuable manure, or horns and hoofs most valuable for the same purpose, or in fact any other material which, though neglected by the ryot for manurial purposes, is valued elsewhere.

With thousands of tons of manure, such as sweepings and stable litter, which caste prejudices would not debar the use of, and yet year after year carried to the Salt-water Lakes and wasted round Calcutta itself, where enlightenment should be found, if anywhere, the use of which would be repaid tenfold in growth of vegetables which would find a ready market, it is idle to talk of opening the eyes of zemindars to the loss the country sustains in the export of bones. Let the Agricultural Department show practically their value, and if the zemindar's eyes are to be opened, that plan will have more effect than reams of correspondence in newspapers only, read by enlightened people who do not need to be told what they already know.

I allude to zemindars, as that class is apparently to be appealed to, though in my experience, zemindars, as a class, are supremely indifferent as to whether a ryot gets a good or bad crop, as long as he pays his rent and various "squeeze."

—*Englishman*.]

D. B.

HOLLOWAY'S OINTMENT AND PILLS will be found the best friends to persons afflicted with ulcerations, bad legs, sores, abscesses, fistulas, and other painful and complicated complaints. Price of and very plain directions for the application of the Ointment are wrapped round each pot. Holloway's alterative PILLS should be taken throughout the progress of the cure, to maintain the blood in a state of perfect purity, and to prevent the health of the system being jeopardized by the local ailments; bad legs, old sores, and grievous, are thus readily cured, without causing any harm to the body, or withdrawing from him or her the necessary food and generous support so imperatively demanded, when such diseases attack advanced years or constitutional weakness or decrepitude.

NEW POISON FOR POTATO BUGS.

Passing through the country on the railway we have recently seen numbers of farms where people were busily engaged picking potatoes off the vines. At a little place in north western Iowa, we had a talk with a druggist about the matter and learned from him that large quantities of Paris green are purchased from him every day. "Just this morning," said he, "I sold six pounds to one man, and am sure it will hardly pay him to use it." We suppose large quantities of this poison and also London purple have been used this summer with little or no avail, but here comes a writer in *Pick's Monthly*, and claims that he has a successful remedy in the shape of the perennial larkspur. He says:

"Every summer after planting my borders and flower-beds, I had some odd seeds left among which were about a dozen plants of perennial larkspur (*Delphinium formosum*). I planted it in a row alongside of a potato field. Every potato grower knows that no matter how carefully and perfectly one applies his Paris green, when the vines are down there are always some bugs left to supply us for the next season. When there are no more potato vines for them to eat, they go for tomatoes, peppers, egg plants, and others belonging to the Solanum tribe. One day when passing my larkspurs above mentioned, I was astonished to see the ground under them covered with dead and half dead and nearly dead potato beetles. Some were on the plants, and of course, I watched them. My observations satisfied me that none of those who trespassed on my delphiniums lived long enough to have a taste of the tomatoes in the next field. There was no apparent injury done to the plants that killed them; but how did they get killed? My theory is that after leaving the potatoes they crawl up everything that comes in their way until they find something that suits their palate, but that even nibbling at larkspur is too much for a potato bug. Perhaps some who read this will experiment on a large scale the coming summer. I certainly shall if the seeds I plant do not disappoint me."

We have never seen the above plant grown for the purpose named, and would but strongly advise our readers to give it a trial. The larkspur is a pretty plant, and if it does no good as a bug preventive, may be used as an ornament. It can at least do no harm.—*Farmer's Review*.

THE NORD-DEUTSCHE JUTE SPINNEREI UND WEBEREI.

We are indebted to a friend for the following interesting account of a jute spinning and weaving mill at Hamburg, which has been furnished by a correspondent of a Dundee paper:—

During a short visit to Hamburg last month, I had an opportunity of seeing a large jute mill there, and as Dundee is largely interested in everything connected with the industry, the subjoined notes may not be unacceptable to your readers. Two years ago a Limited Liability Company, called the Nord-Deutsche Jute Spinnerel und Weberei, Hamburg, was formed, with a capital of £30,000, which has since been increased to £120,000. About six acres of ground at Schiffbeck, on the Billa, seven miles from Hamburg, were bought, and extensive works were erected. The buildings are all of one story, have a frontage to the river of 600 feet, and are 300 feet wide. When the establishment was opened in January last year, there were 128 looms and 2,700 spindles, but the demand for goods was so great that additional machinery was soon required, and there are 240 looms, with 400 spindles, in operation at present. The buildings were set down for 320 looms and 5,000 spindles, so that there is yet considerable room for extension; but if the same progress is made in the future as has been done in the past eighteen months the whole accommodation will shortly be required. Between 750 and 800 hands are employed, and the quantity of cloth turned out is about ten tons per day. The works are fitted up exactly on the same principle as those of the best factories in Dundee, and, in fact, a good deal of Dundee machinery is used. The whole of the machinery in the spinning department was made by Messrs. Lawson, Leeds, while the rest came from the works of Messrs. Robertson & Orchar and Parker, Dundee. At first sight the distance of the works from Hamburg might be considered a disadvantage, but a little consideration shows that it is not so. Labour is cheaper at Schiffbeck than at Hamburg, and by having the works placed beyond the boundary of that town the manufactured goods can be sent to any part of Prussia free of duty. That of itself is a great advantage, for had the factory been in Hamburg a heavy duty would have been leviable and the Company would have been unable to compete with British manufactured goods on so favourable terms as they can do under existing circumstances. The raw material is either imported direct from Calcutta or bought in London. On reaching Hamburg it is transferred to barges in which it is carried to landing-stages opposite the works, and thence by railway to the warehousing and preparing departments. It is unnecessary to describe at length the processes by which the jute is manufactured into cloth, but it may be mentioned that hand-batching is preferred to the use of machinery. After being batched the jute goes through the preparing, spinning, weaving, and dressing processes till it is ready for the loom; and the quality

of cloth turned out will stand comparison with that produced in any similar establishment either in Dundee or on the Continent. None of the cloth is exported, the whole being consumed in Prussia. Unlike the Dundee mills, many of which are working short time, the Nord-Deutsche, in order to overtake orders on hand are obliged to work overtime. The working hours are sixty six per week—from six o'clock in the morning till seven at night—and when I was there part of the machinery was kept running till eight o'clock. The operatives, with the exception of a dozen Scotch spinners and weavers, are Germans. All overboard the average wage is from 10s to 11s per week, spinners receiving from 9s to 12s; winders, from 12s to 15s; and weavers, from 14s to 18s. Although the hours of labour there are ten per week more than in this country the quantity of work turned out is about the same as with us. There are various causes to account for this, two of which might be mentioned. In the first place, a Scotch hand is superior to the average Continental workman, and does more and better work than the latter; secondly, a good deal of time is lost by the employees staying out on Mondays. The wages are paid once a fortnight, and it is not uncommon for from 150 to 200 hands to fail to put in appearance on the Monday after pay Saturday. In fact, I was back on a Monday and the manager told me that on that occasion 200 of his employees had come in. Many of the workers, he said, are quite listless on Tuesday, and it is not till Wednesday that everything is in full working order. The Germans go in for enjoying themselves on the Sunday, and the result is that many of them are unfit or unwilling to work on Monday. Near the works there is a large park—a very popular resort of the workers. Amusements of various kinds are provided. Many of the frequenters dance all Sunday night and up to six o'clock on Monday morning. Little wonder need be felt that they are disinclined to commence work. The factory is lit with gas made on the premises; and there is a fire brigade connected with the works, consisting of 20 members, with Mr. John Cargill, the manager, as captain. One part of the buildings is used as a dining-room, and 450 persons daily take advantage of it. Provisions are supplied by a merchant who has also charge of commodious premises belonging to the company in which about 200 of the hands are lodged and boarded. For the benefit of the Scotch workers a Presbyterian service, conducted by the Rev. Mr. Atkinson, minister of the Reformed English Church in Hamburg, is held in the manager's house every alternate Thursday evening. I attended one of the services, but was rather disappointed to find that of the eighteen or twenty who were present, only five were workers. In explanation of the small attendance it was stated that a number of the girls were unable to be present, being engaged working overtime while the meeting was being held. It may be mentioned that two commercial directors connected with the Company—Mr. F. Friedmann and Mr. Max Meyer—were at one time engaged in business in Dundee.

KEEPING MILK FRESH.

This is a subject which has caused the dairyman and general farmer much trouble. Even with the greatest precautions; milk-coolers, ice, well-water, running water, and cool cellars, he has found that in certain conditions of the atmosphere, it is almost impossible to keep milk sweet and fresh. Not only has this difficulty been experienced in keeping milk, but also in preserving meat and other articles of food in a healthy condition for human food. We have recently heard of many cases of poisoning from the consumption of dried beef which had been tainted while in the butcher's hand, and from this cause some deaths have occurred. This being the case, it would be a boon to farmers and others were some reliable preservative invented to keep milk and other commodities fresh. An English exchange offers a recipe which seems to promise good results, and is at least worthy of experiment. This compound has been named "Glacioline" by the inventor, who claims that it will preserve meat and fish, poultry, game, eggs, butter, milk, cream, and also vegetables, fruit, fermented liquors and other substances, and liquors affected by age, by an increased thermal condition, by change in the state of the atmosphere and otherwise. It consists of a combination of water, hydro borate, sodio diborate, glycerine, and in some cases white sugar, urate of potash and common salt. These ingredients may be compounded together in variable proportions relatively with each other, but it is preferred that the following proportions be employed as best suited for the purpose of this invention, viz., in each gallon of pure water, and which is employed at atmospheric temperature are dissolved of

		Avoidupois.
Hydro borate	...	9 ounces.
Sodio diborate	...	41 ounces.
Glycerine	...	41 ounces.
White sugar	...	3 ounces.

Or the sugar may in some cases be dispensed with. This liquid preservative is especially valuable in that it consists in a large proportion of hydro borate, obtained in a solid or stable state, the said substance being rendered much more soluble and more efficient by means of the other antiseptic ingredients above mentioned.

Any druggists will be able to compound the above preparation from the recipe given, and we should think that every farmer will find it valuable. Common boracic acid, being procured, can also be purchased of the wholesale druggists, and may be used with impunity, being tasteless and harmless, and its action on the milk.—*Farmer's Review*.

HOP-PICKING AND HOP-PICKERS.

To dwellers in the north we suppose a hop garden is almost as novel a sight as a vineyard. And, indeed, there are many persons who consider it quite as picturesque, especially when the hopbines are twined round strings stretching from the tops of tall poles, so that the visitor walks beneath a beautiful web of greenery from which hang the lovely clusters of hops. The other and more old-fashioned method is also eminently picturesque. The poles are still taller, and are placed in groups of three on little "hills"; the bines are trained up the poles, the tendrils interlacing with one another, the bunches of flowers mingling with leaves until each group forms quite a little bower. There is an average of 1,210 of these groups to an acre.

To numbers of people the hop-picking season, which usually begins in the early days of September, is a joyful, healthy holiday, the attractions of which are simply irresistible, especially as the light labour enables many a poor peasant and half-starved East-ender to obtain a little store of cash, as well as health and pleasant memories for the dark days of winter. But there is no thought of winter in the rich mellow September sunlight, lying so warm and still on the long line of broad-leaved hop plant, with their golden, healthy-scented flowers! The sky is clear, the autumn wind is scarcely felt, the laugh of women and children rings merrily out, jests and good-humoured "chaff" abound; here a song is lightly sung, and everywhere is cheery chat, as pole after pole sways hither and thither in the sunlight, its bine is broken, and finally it is thrown across the sackcloth bin, where busy fingers soon strip off its yellow treasure! This is hop-picking at its best. Of the wet days that darken the scene, of the excesses that sometimes disgrace the pickers, let others tell! Such a chance of combining business and pleasure, of mingling healthy labour and holiday delights, is not to be lost sight of; and from the squalid courts and alleys of the great metropolis, as well as from the quiet little cottages of the country village, some thousands of poor folk every year look forward with joy to "go in" for "go in" oppin'.

Formerly the poor folk used to tramp down the long country roads from London, or they would crowd into some ricketty conveyance and journey along in as dignified a manner as possible by donkey-cart, or behind a bony horse. But now the railway companies run special cheap hop-pickers' trains, which are largely patronised. The departure of these trains is a sight worth seeing. Women and children in, one might say, almost every stage of poverty, rags and dirt, and burdened with very nondescript baggage, mainly crowd the platform in the grey, chilly morning light. There are a few men slouching about; but many of these have preferred to tramp off along the road and save the scanty fare, leaving the women and children to come by train with the luggage. And such luggage! Pots and pans, kettles and teapots, loaves and potatoes, all crammed together into a worn-out sack or broken basket. Here is a poor woman with a bundle of bedding, a baby in her arms, and another dragging at her ragged skirts; there is a boy with an old clothes basket of crocks and pots and meagre provender. But at last the porters and the guards coax and command the motley crowd to stow themselves into the carriages, and then, as the first faint rays of dawn are flushing the sky over the Thames, the heavily laden train steams slowly south. To watch the departure of a Scotch mail for the moors and then shortly after to witness the hop-pickers start for their holiday of light labour is not the least striking of the many striking contrasts that mighty London has to show.

Arrived at the station, the hop-pickers straggle off one after the other along the hot, dusty roads to the gardens of the grower from whom they hope to obtain employment. The poor people have often a long and tiresome journey, though no doubt some of them enjoy the pleasant change from the hard pavements of town. But after a time the bundles become very heavy, the children get tired, and the sun is hot. Nevertheless, they struggle along somehow, and perhaps a kindly waggoner will give them a "lift." Several of the hop-growers, however, now send their waggons to meet the pickers at the station. "Hoppers' houses" are also provided for them. These buildings are rough wooden structures—one for the men and another for the women—with usually a grate for cooking and plenty of clean straw for bedding. Other farmers permit them the use of a piece of waste ground or the corner of a field, where they may erect little tents or old hop-sacking to shelter them during their fortnight or three weeks' sojourn. And in the pleasant lanes and sweet-green fields of Kent, and Surrey, and North Hants at this season, many such little

encampments may be seen nestling under a tall hedge or on the lee side of some rich copse, with the blue smoke of the wood fire rising slowly up into the clear sky. The hop-pickers enjoy their picnic quite as much as do their wealthier neighbours.

The "hoppers" rise early in the morning, and while yet the dew is thick on the fast-fading foliage, and the birds are few in the sky, they take their way to the hop garden, the only sound in the still air being the chirp and twitter of the "mallard" and "birds." Altogether a happy and a wholesome change from the foul dens and rookeries to which, alas! the hop-pickers will return all too soon! Arrived on the ground they speedily commence work. Usually they are divided into two parties, the people from the neighbourhood being in one, and those from town in the other "set." Each party has an "overseer," who is constantly on the spot, and at noon and at evening the "hoppers" the hops that have been picked. There are also a number of "pole-pullers" attached to each "set." The pole-puller's business is to cut the hop-bine about a foot from the ground, so that it does not "bleed" too much, and then to pull up the pole with an iron-rope "dog," so that it is not injured, for the poles are an expensive part of the hop-grower's stock, and have to last several years. The pole, covered with its leaves and flowers, is then placed across a "bin"—which consists of a large open-mouthed sack stretched round a wooden frame—and the hops picked into it. Leavers have a curious disposition to find their way into the bins also, and the cry of the pole-pullers as they walk about the ground, "Pick out your leaves! pick out your leaves!" is quite one of the characteristics of the hop garden. As the sun reaches the zenith, and noon draws on, another cry is heard of "No more poles! no more poles! no more poles!" The first "measuring" is to begin. Bushel baskets of wood or wicker are given out, and a long line of empty "bins" is placed along the hop ground. Before each one of these in turn the overseer takes his stand, and to him the pickers bring the contents of their frames in the bushel baskets afore-said. For each bushel a metal ticket is given, and these precious tickets are hoarded as carefully as money.

A sharp eye has to be kept on the pickers: that they fill up their measures. For there is great art displayed in filling up the bushel lightly, so that seven-eighths shall appear like a whole! And if the "misurum" frame is a little distance off, the troublesome hops will perversely shake down, and then the ragged child, with long tangled brown hair hanging around her sun-tanned face, will endeavour to surreptitiously empty the hops into the frame before the lynx eye of the overseer can notice the delinquency. "Fill up your bushels, fill up your bushels!" is frequently heard; and as a rule we fear sufficient attention is not paid to it. At last our patient friend loses his temper a little, and the giving of a few three peck tickets instead of full bushel tokens generally reduces the most refractory to reason. Ah! but it is a sight to see how artistically the women round their arms as they bend over into the frame, and gently lift and coax the hops lightly into the baskets. How great are their efforts to make three pecks go to the bushel! It is seldom a man is seen filling the baskets; he is far too heavy-handed, we suppose; he would be more likely to crush in five pecks instead of four! He may carry the basket to the "misurum" frame if he does not jolt the hops down too much. But we fancy he is shy of this little business, for hops will jolt down if the basket is not well filled, and then sometimes we hear him get such a "tongue-banging" when he returns. This is sad, in the pleasant warm sunshine—especially so, he thinks, as there is no "pub" round the corner as there is at home to which he can retire for shelter! Certainly the student of human nature may find much to observe in the hop-garden.

The amount of money earned by the pickers varies very much. If the weather be dry and the hops large, the number of bushels picked will be larger; if the weather be damp, it causes the hops to lie close in.

In the measuring baskets if the hops be small and poor, a much longer time is necessary to pick a bushel. In such a season the grower often gives a penny or two pence per bushel extra; the average price being three or four pence per bushel. Thus, the expenses being light, a small family, if industrious, could easily make £3 or £4 to take back with them to their London homes, after enjoying a happy and healthful holiday. Unhappily, drink too often plays havoc with their earnings. And when the last pole has been pulled, and the gardens—recently the scene of so much happy and healthy labour—are deserted, when the last load has rolled home to the kiln, and the joys of pay-day have come, then too often the pickers change their bright gold for treacherous liquor, and the pleasant country byways show disgusting sights of stiffs and drunks.

Of late years much has been done to improve the hop-pickers' lot, and to shield them from temptation. Mission societies, and hop-picking districts, and various home missionaries, have been established, and much real and practical good has been accomplished. But the happy, healthy season, when the hop-pickers dole back home, and the hop grounds teemed with their treasures are left to the autumn wind and rain,—Paul Mart Regent.

THE INDIAN AGRICULTURIST.

A WEEKLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY, AND STATISTICS.

VOL. X.]

CALCUTTA — SATURDAY, OCTOBER 31, 1885.

[No. 44.]

Health, Crop and Weather Report.

[FOR THE WEEK ENDING 21st OCTOBER, 1885.]

At dres.—General prospects fair continues favorable in Bellary and Anantapore.

Bombay.—Rain in parts of eight districts, more still required in parts of Guzerat and Khandesh. Reaping of *shil* and sowing of *rahi* in progress in several districts. River still falling in Sind. Standing crops suffering from deficiency of water, and damaged by rats, insects, and storms in parts of Hyderabad. Cholera in parts of thirteen, fever in parts of sixteen, cattle-disease in parts of eight, and small pox in parts of three districts.

Bengal.—Slight rain has fallen in almost all districts of Bengal proper but none in other parts of the province. Prospects of *amrit* rice except in places visited by inundation, are generally favorable, but some more rain is now much required in many places. *Asu* rice and other *bird* crops, where not injured by floods, have yielded a fair outturn. Price of rice continues high, though in several districts it has fallen slightly. Fever is prevalent in some districts; otherwise the general health is fair.

N. W. Province and Oudh.—Fair weather is reported from all districts, but rain would be beneficial in most. *Kharif* nearly harvested, and *rahi* sowings in progress everywhere. General prospects good, markets well supplied, and prices steady. Cholera and fever continue to be reported from some districts; otherwise public health is good.

Punjab.—No rain. Fever prevalent in the Hissar, Delhi, and Peshawar districts; otherwise the health of the province is good. Rain much wanted in the Jullunder, Ferozepore, and Bealkote districts. *Rabi* operations in progress. Prices falling in the Mooltan district stationary elsewhere.

Central Province.—Prospects everywhere favorable, except in Rampore, where rain is wanted. *Rabi* sowings progressing. Health good. Prices steady.

British Burmah. Cholera severe in two districts, slight in four districts, elsewhere public health good, cattle disease slight in eight districts, elsewhere health of cattle good. Crop prospects good in all districts, except Thayetmayo where more rain is wanted, and in Meigul, where the crops have been partially flooded.

Assam.—Weather seasonable. Public health improving; cattle-disease still in some mauzams. Portion of *salt* crops reported to have been destroyed by insects in some villages. Prospects of crops fair. Tea doing well. Common rice 14 seers per mpee.

Myore and Coorg.—Tanks in the Bangalore and Tumkur districts are reported to have received good supply of water. Standing crops in good condition, sowing of *ragi* and horsegram continues throughout the State. Season prospects and public health good. Six deaths from cholera reported in the Sorab taluk of the Shimoga district, cattle in good condition, excepting in parts of the Kadur and Shimoga districts where maula still prevails. Prices slightly falling in Bangalore, and risen slightly in Mercara. Picking of coffee crop commenced in South Coorg.

Bombay and Hyderabad.—Weather cloudy in Anraoli, where cotton picking commenced, *rahi* sowing progressing. Wheat 22 and *rahi* 28 seers per rupee. Crops progressing favorably and *rahi* sowings in hand in Akole. Standing crops good, *rahi* weedings continue, in Hyderabad general health fair except in some places, where fever prevails. Prices in Hyderabad: wheat 13 coarse rice 12½, white *rahi* 19½, yellow *rahi* 24½, and *rahi* 15½ seers per current moka rupee.

Central India States.—Prices stationary. Health good, little water in wells and tanks in Indore. Weather seasonable, 29 cases of cholera in Berhampore; cholera generally prevalent throughout the agency. Prices falling in Behara. Prospects improving in Manipore, where water-supply still scanty.

Rajasthan.—Bright warm days with passing clouds. A little fever. Trade, wells, and health good. *Rabi* and *moong* out. Health much improved in Marwar, but cholera still hangs about. Crops suffered much from want of rain in Marwar, where prices rising. *Shil* very poor; prospects for *rahi* not overpromising in Khetwar. Crops withering through want of rain in Marwar, where fever is prevalent and prices rising. Rain much wanted in Harwar. Cholera in Pachpabar district, in Dholapoor, tanks drying; withers. Fever continues.

Nepal.—Prospects good.

Letters to the Editor.

FRUIT FARMING

TO THE EDITOR.

SIR,—Could any of your friends say in a few words—not to trouble them too much—in what part of the world could Fruit-farming be tried with the best prospect of success, and the smallest amount of capital that a start could be made upon—owner being minded to stick closely to the work himself?

SUBSCRIBER.

October 19, 1885

TESTING SILK.

I

TO THE EDITOR.

SIR,—Will your able and experienced correspondent, Baboo Hem Chandra Dutta, oblige me by kindly telling me the best method of testing silk, and also how to feed the thread from the gum, if the silk becomes stiff and harsh.

"SILK."

Dinapore, October 20, 1885.

II.

TO THE EDITOR.

SIR,—In reply to "Silk," I would say that potash and soap are the only ingredients for testing silk. To feed the thread from the gum, if the silk becomes stiff and harsh, I would also suggest a trial with potash and soap, which will cause it to feed freely from the gum.

H. CHUNDEA DUTTA.

October 26, 1885

MANGO PESTS, &c.

TO THE EDITOR.

SIR,—I beg to thank you and Mr. Hem Chandra Dutta for the valuable replies to my questions on "Mango Pests, &c," and to state at the same time that I shall take the earliest opportunity of trying the suggested methods, and will intimate the result to you in due course.

A. GURUMURTY.

HYBRIDIZATION OF WHEAT.

TO THE EDITOR.

SIR,—I have read some notices in your paper on the subject of hybrid wheat, but cannot remember seeing any account of the manner in which the hybrids are obtained; in your issue of 10th instant, page 503, it is stated that natural cross fertilization is physically impossible, the process being only practicable by the most carefully practiced expert.

I should feel obliged by your referring me to any issue of your paper in which the manual of producing the hybrids is detailed; I ask because I might be able to induce some of the agriculturists in this division to try experiments if the process is not too difficult.

ED. S. OMMANNEY, COLONEL, Commissioner, Derajat.

October 15, 1885.

NOTE.—We are very glad to receive this letter, and hope to notice this subject at length next week.—ED., J.A.

TEA PLANTING.

TO THE EDITOR.

SIR,—In your issue of the 24th instant, "A Would-be Planter" asks me to answer a series of questions regarding Tea-planting.

In reply I would advise him, like you, Sir, not to rush into such a speculation with such entire ignorance of the subject, *except he secures the services of an experienced and honest tea-planter*. However, the following might help him :—First : climate is the most important of all ; and from my own experience I can say that in several districts of Bengal and Behar, tea cultivation may be carried on most successfully, because, the best climate for tea is a hot, moist and steady one ; and the districts I have named possess such a climate. In a forcing climate the tea plant revels. Secondly : Rotten fish mixed with wood of coal ashes is the best manure, and will in no way affect the flavour of the tea. *Thirdly* : A really good tea climate is neither safe nor healthy for its owner to live in. Fourthly : Elevation is not necessary for tea cultivation, but only for the benefit of the planters. Three to four thousand feet would be quite enough. Fifthly : If the soil is good and seasonable, and garden cooties competent, then one man per acre, or else, three men to two acres would be sufficient. And lastly, there is scarcely another investment so paying as tea.

HEM CHUNDRA DUTTA.

October 28, 1885.

P.S.—I have not seen the *Vade Mecum* you refer to, but I would suggest to your correspondent to procure also Colonel E. Money's *Essays on Tea*.

MILK AND ENSILAGE.

TO THE EDITOR.

SIR,—Will you pardon a Cirencester graduate for pointing out that the composition of milk in its various stages is not a matter of opinion, but a scientific fact ? The first milk after the calf's birth, which you stigmatize as "*poor*," really contains five times the quantity of albumenoids as is found a week later in the same cow's milk. After this the constitution of milk remains fairly constant for some time, the exact period varying with the breed of the cow, the nature of the food, climate, etc., but after this period, the yield of milk diminishes in quantity, but improves in quality. This is true of all animals, including human beings. If you have found milk becoming thin as it diminished in quantity, the *goats* must have watered it.—A few words as to ensilage. In my first letter I pointed out that the value of ensilage would be proved by the experiments carried out by Sir John Lawes. I have not seen his report, but from a reference you make to it, I find that ensilage when given with other food, almost if not quite equals mangels when given with the same amount of other food. I saw the silos from which this ensilage was taken being filled. The silos were specially constructed at a cost of £200 to hold 200 tons. The fodder used was the best pasture grass and oats cut green, and it was packed as carefully as possible. In fact, it was the best ensilage that can be made, and yet the result was that as a milk-producer it was inferior (slightly) to mangels, and as a fattening food no better than the same root. Now mangels contain 88 per cent of water, and less than 1½ per cent of albumenoids, even if all the nitrogen they contain is treated in accordance with the old method as albumenoid ; but later investigations have proved that much of the nitrogen is non-albumenoid, and therefore the real feeding value of mangels is nearly, if not quite, as inferior as the worst food ever fed to stock in England. In any case it is far inferior in feeding value to the grass and green oats from which this ensilage was made. It may pay a farmer on certain kinds of land, and in certain climates to go in for ensilage instead of roots ; but no one surely will any longer argue that the process of ensilage improves the feeding value of fodder. No farmer in England would attempt to fatten stock on ensilage alone, any more than he would try to do so on roots alone ; but stock can be fattened on exceptionally good pasture alone, but even then it is usual to give a little cake or corn. The main value of ensilage in India is that it is a means of storing food when it is plentiful up to the time when all other food is scarce. To ascribe higher qualities to ensilage will, I fear, do more harm than good in the long run to this process of storing fodder, which should prove a great blessing to the Indian cultivator.

D. B. ALLEN.

October 24, 1885.

Editorial Notes.

We publish this week an interesting extract on the rates and methods of sowing wheat, and the results obtained at the Indiana Agricultural College. An experiment on this method in some of our agricultural farms would prove of interest. We think.

**

We publish this week two papers on the agriculture of Finistère, and Irrigation at the Lézardeau School, Finistère, by B. C. Basu, Bengal Agricultural scholar at the Royal Agricultural College, Cirencester, which will be read with interest. This young gentleman ought to make a good officer under the Agricultural Department.

**

A CORRESPONDENT writes to the *Stateman* as follows :—Notwithstanding the unusual prevalence of floods in several parts of Lower Bengal and Orissa, which have greatly injured both the *ajon* and the *aman* crops, especially in the riverian districts, hopes are entertained that there will at least be a twelve-anna outturn ; of the *Salai* (cereal) it is confidently expected that there will be more than a bumper crop, serving in no small degree to recoup the agricultural classes for the very heavy losses sustained by them owing to the recent floods.

**

A very curious article appeared in one of the local papers regarding an "electric tree" said to have been discovered in New Guinea by a party of German explorers. The whole reads extremely plausible, but we are somewhat sceptical about the *bond fides* of the writer, who may be "trying on" a gigantic fraud to test the 'gullibility' of a too credulous public. But, to quote the immortal William : "There are more things in heaven and earth, Sempronius, than are dreamt of in our philosophy." We leave our readers to judge for themselves, as the article will be found elsewhere.

**

News has been received at Simla of the enforcement of the embargo on the exportation of Arabian horses from Bagdad the informers receiving half the value of the horses seized. The whole of the batches of horses bound to Bombay were seized between Bagdad and the Persian frontier. Many animals from other less strict willayets reach Bombay, but if present measures are maintained, there will be a sensible diminution in the number of Iraki and Arabian horses reaching the Bombay markets, while there will be a corresponding increase in the number of Persian horses bought in the vicinity of Muhamra, which is a consequence of there being no embargo at the principal port of exportation.

**

We learn that Dr. Fairbank, of the American Mission, is doing good work at Ahmednugger by inducing and assisting men of the low castes to take to agriculture. He advances them money to take up a little land, purchase implements and cattle, &c., on the understanding that they must pay 6 per cent interest per annum punctually, and also repay 6 per cent of the principal every year. The scheme is said to answer very well, and a number of Mahars have taken up land and are working it successfully. Last year Dr. Fairbank lent money to twenty-five of these petty farmers to buy seed, and "although the *kharif* crops failed and the *rabi* crops were very poor, the money was all paid back to him within the year."

**

A BOMBAY firm is advertising Russian kerosine for sale ; and this is the first time, probably, that the produce of the famous wells at Baku has reached India. Last year, India imported over 26½ million gallons of kerosine ; and nearly all of it came from the United States. Should the Russian oil be able to compete with American kerosine, Russia will rapidly move up in the list of countries trading with India. At present the United States has 3·07 per cent of the total value of our trade ; and Russia only 0·08 per cent. The importation of kerosine oil into India has increased, of late years, enormously. "Kerosine," says Mr. O'Connor in his trade review,

is now used everywhere, in towns at least, for illuminating purposes, and in the littoral provinces and places convenient to railways, it has extensively displaced the vegetable oils formerly exclusively used by natives for lights."

THE first report on the prospects of the Cotton Crop in the Bombay Presidency is as follows:—

Cotton forecast—Gujarat: figures for Kathiawar and Baroda not received; area for Broach, Ahmedabad, Surat and Kaira 575,000 acres, as compared with average 550,000 acres. Early rains favourable, but long break caused withering and damage from insects, good rain has now fallen, and prospects good. **The Deccan:** figures for Khandesh not received, but estimate 650,000 acres, crop below average in quality; rain late; Poona, Ahmednagar, Sholapur, and Nasik area 25,000 acres as against average 125,000 acres, worse even than last year. Satara return not received. **Southern Mahratta Country:** returns not received, season very late and sowings not complete, late rain promises excellent prospects. **Sind:** returns not received. Incompleteness of returns prevents further remarks."

THE state of the cotton trade at home has assumed a serious aspect. The Overland Mail notices the subject as follows:—

Never, perhaps, since the great cotton panic, over twenty years ago, has trade in North-East Lancashire been so depressed as it is at present. In the district between Preston and Colne, and including the great cotton centres of Blackburn, Burnley, Darwen, Accrington, and Rossendale, there are about thirty cotton mills entirely stopped, and at a large number of places the machinery is only partially at work. "From returns recently compiled, it is estimated that in North Lancashire, with Rossendale included, there are nearly 1,000,000 spindles and 50,000 looms standing, which if at work would find employment for more than 20,000 people. In Blackburn there are 5,000 cotton operatives out of work, in Preston nearly 4,000, in Burnley 2,000, in Darwen 1,500. Many of the small firms have succumbed to the severe depression, and not a few of the large concerns are losing money. Mill property is depreciating enormously. Unhappily, the outlook is no brighter than has been the immediate past; indeed, unless there is a wonderful change for the better, the machinery standing idle, already lamentably great, will be considerably increased."

THE Revenue and Agricultural Department of the Government of India have issued the following memorandum on the prospects of the rice crop in British Burmah:—"Up to the end of September the area actually under paddy crop is 168,920 acres above last year's area, giving an increase of 5.5 per cent. The increase is common to all districts, except Bassein, where there is a decrease of 17,859 acres in consequence of cattle disease and floods. The ploughing and transplanting season was about a fortnight later than last year, but the rainfall has been plentiful and seasonable, and crop prospects are reported to be for the time of year good everywhere, except in parts of the Prome district. No estimate can yet be framed of the outturn, as everything depends on the rice-fields getting a moderate but sufficient rainfall throughout October. Up to the 11th October the rainfall of this month in and near Rangoon has been decidedly favourable for the rice crop."

A CONTEMPORARY says:—It may interest those concerned in agriculture to know that there is a flourishing town called Kanigal, the head-quarters of a taluk of that name, within about 12 hours' journey from Bangalore, or sooner if rail and dak are used. The climate is good; there is a small dispensary, and the Mysore Government has its horse-stud establishment located there on account of its many farm advantages. It has a large tank commanding a good supply of water all the year round, and the assessment of lands below it is favourable to the cultivator. There are actually 808 acres of cultivable wet land, assessed at Rs 4,424-8, available at the present moment, and if it is taken up and cultivated, the produce of straw alone would be sufficient to recoup any small outlay; all the paddy would be clear profit. Here is an excellent chance for enterprising capitalists, who can get the lands for the mere asking. The sluices and irrigation channels are almost all in fair order, and the Government authorities are giving their best attention to remove hindrances, &c., in their wherever found.

We learn that Dr. Trimen has had a very interesting botanical trip through portions of the North Central, Eastern and Central provinces of Ceylon, working more especially along the sides and within the triangle formed by the roads from Dambulla to Anuradhapura, thence to Trincomalee, and from Trincomalee back to Dambulla. Dr. Trimen visited Pollenaruwa and Mineriya lakes, which he thought most interesting; and altogether this trip has more than ever impressed him with the great variety of country, scenery and resources possessed by the island. Scarcity of water at some of the stopping-places was the chief drawback to comfort encountered, and no one can form a true idea of the many ways in which water is indispensable to the convenience as well as comfort of living, until they find absolutely none to be got for miles around their habitation! What struck the travellers was the absence of "wells": where such existed the villages are comparatively independent; and as wells are much easier made than tanks, we may ask why are wells not found at every village, and indeed every possible stopping-place on the roads referred to? In India the authorities apparently pay a good deal more attention to well-digging than is the case in Ceylon so far as we can judge.

A CONTEMPORARY says:—

The Americans have "discovered a plant" which, if properly used, may prove to be one of the most important additions to human life that the world has ever seen. It is called "the laughing plant." Not that the vegetable itself laughs. It does not even smile; but its seeds, if eaten, incite to immoderate mirthfulness. It is described as bearing flowers of bright yellow, and soft and woolly seed pods, in which are inclosed small black beans. The natives of "that part of Arabia in which the plant grows" dry and pulverise these beans, and if this powder is administered "it makes the soberest person behave like a circus clown, for he will laugh, dance, slug, and out the most fantastic capers. The effect lasts about an hour, at the end of which the 'patient' recovers his normal gravity, and is altogether oblivious of his extraordinary conduct when under the influence of the powder."

The plant would appear to belong to the leguminous order; but being a recent discovery, we suppose it has not as yet received its botanical name.

A FRENCH correspondent sends the following on the subject of open-air silos to one of the American papers:—

"M. Houlez, the discoverer of the plan of preserving green forage in the open air, continues to record his uniform success. The whole secret of his open-air silo consists in uniform and uninterrupted pressure, so as to secure the expulsion of the air, and thus prevent the decomposition of the mass. The silage should be carted to the place for stacking, as soon after being cut as possible. There is no necessity to wait for its being dried; humidity is not at all an obstacle; nor is rain, save when it interferes seriously with work. Spread the forage uniformly, keep the stack from leaning, pile up slowly, so as to allow the mass to settle down little by little, and the fermentation to commence, thus securing tenderness in the forage. Select planks sixteen inches wide and one inch thick; allow them to project a few inches over the side of the stack. Cover the planks with earth, firewood, stones, &c., at the rate of 23 cwt. per square yard. To open the stack for use, it could be constructed on the principle of a series of parallel walls, and so obviate all difficulty. The drawback of the open-air silo lies in not being able to count upon keeping the erection of the stack perpendicular."

A CORRESPONDENT sends to a Bombay paper on account of a most interesting experiment carried out by Dr. S. Cooke, of the Poona College of Science, which promises to solve the problem that has so long baffled municipal bodies, town corporations and even scientists. If Dr. Cooke's discovery, for which, it is stated, he has secured a patent, is really what the correspondent represents it to be, the Doctor must be regarded in the light of one of the greatest benefactors of the age; for not only does his discovery dispose of a most vexed question that has long formed the subject of much discussion and speculation in this country, but it adds a most important item to agricultural fertilizers. The subject of converting the refuse of towns into poudrette has been discussed in these columns from time to time, and Dr. Cooke's discovery would appear to be an improved form of manufacturing this substance. The result obtained by him in the experiment of applying his

fertilizer to a plot of ground at the same time with other ordinary manures, speaks volumes in favour of his discovery. The letter itself on this subject will be found elsewhere. We should, however, like to hear more about Dr. Cooke's discovery.

Writing on the subject of ensilage for milch cows, an American contemporary states that the experiments and experiences of the past two years are thoroughly confirmatory to the idea, that if in the filling, or immediately thereafter, a high heat can be induced which shall pervade the mass in the silo, and then, all tightly closed, the ensilage will remain sweet until it is re-opened, and an opportunity to ferment is offered by exposure to the air. These results are attained by not too rapid filling, nor too much tramping, the temperature being watched, and as soon as that of one layer or portion reaches, say 130 degrees Fahr., another layer, three or four feet in thickness may be added, levelled off, packed a little around the sides and left for a day or two to heat in turn. Pits filled in this way last year turned out beautifully, and the cattle, especially milch cows, have had healthful, excellent feed, fragrant and sweet, and, of course, highly relished. When such can become the general or universal condition of ensilage on good farms, the objections to its use will disappear. Heating of ensilage is promoted by cutting, by which the juices are exposed to the action of ferments, the germs of which are almost universally distributed in the atmosphere near dwellings and farm yards. The very fine cutting which used to be recommended, is probably unnecessary, but neither corn nor clover, when packed whole, come into a uniform heat, and we presume the same would be true of other ensiled plants.

The Americans have been experimenting with ensilage in every form. In contrast to the foregoing, Mr. Monroe Morse, president of the Franklin (Mass.) farmers' club, says that he filled his silo last season with green sweet corn fodder put in whole, and carefully packed and trodden. The expense of filling was much less than if the corn had been chopped, but at the sides of the silo there is more corn injured by loose packing, than if it had been cut fine. It is less work to feed it out, as it can be taken up by the forkful without the use of baskets. About three weeks were occupied in the filling, and a high degree of heat was generated, though the temperature was not tested by a thermometer. The silo held more ensilage than if the corn had been cut with a machine, as it settled more and became very solid. The silo was filled completely full two or more times, settling enough each time to take in several large loads of fresh corn at a time. The ensilage comes out sweet, and is eaten with great avidity by the cattle. Many of the stalks had small ears of corn attached, and these also came out sweet and sound, better than last year when chopped. Mr. Morse is satisfied that it is better to be three or four weeks filling a silo so that the contents will be heated to a high degree of temperature.

With reference to the representation of Ceylon at the Indian and Colonial Exhibition, it is stated that the suggestion made by the Secretary of the Royal Horticultural Society, that a selection of suitable plants should be sent from Ceylon to be placed in the Ceylon Court of the forthcoming Indian and Colonial Exhibition in London, is being acted upon, though it is to be feared the arrangements are rather late, the cold, on the arrival in England of any plants now being shipped, being likely to try them very severely. There are but few Ceylon plants which are likely to resist the drought and cold of the Exhibition building. Such as are thick-skinned and hard-leaved may prove a success, and, accordingly, about a dozen fine specimens of the madu, or sago palm, and the juddi, or date palm, have been selected for shipment, with stems nine or ten feet high. A similar number of the beautiful tree fern will also be sent from Ceylon in a few days, in the hope that they too may survive the cold of the latter portion of the voyage home. On their arrival they will be handed over to the officials of the Royal Horticultural Society, who will winter them in their hot-houses on the ground at South Kensington adjoining the Exhibition buildings, whence in May next

they can readily be transferred to the Ceylon Court. The trophies of sport, if successfully treated, should form very attractive objects, and by careful daily attention they may be carried through all the ordeals to which they will be subjected. The tree ferns, even though their vitality suffer, would still present very attractive features; if we are not mistaken, these plants are not to be found in any hot-house in England, and they will therefore prove a great novelty.

The Ceylon Chamber of Commerce have published their returns of the export season just closed made up to the end of the fiscal year, 30th September, from which it appears that there was less coffee shipped than last year, viz., 312,111 cwts. against 323,941 cwts. last year. Cinchona shows an increase from 11,492,947 to 12,697,830 lbs. The exports of Tea have exceeded the estimate of 2,500,000 lbs. by 269,684 lbs. The following is the table of distribution of Ceylon exports from 1st October 1884 to 30th September 1885:—

COUNTRIES.	Coffee.	Cinchona.		Tea.	Cocoa.	Ceylon Rubb.
	cwts.	Bark lbs.	Trunk lbs.	lbs.	cwts.	
To United Kingdom	2,30,084	10,88,575	90,57,092	27,35,600	6,011	1,27,872

The Ceylon Times, writing on the future of the Cinchona trade and cultivation in Ceylon, says that the satisfactory prices realised at a Cinchona bark sale reached as much as 30 cts. for 1 per cent bark per unit. "The rise was no doubt due to the receipt of intelligence from London quoting the unit firm at 6½d. As times go, this cannot but be regarded as a fair price, 3 per cent bark being worth very nearly a rupee a lb. Should prices continue at all as at present, we do not believe that the falling-off in the year's exports will be so very great after all. There is, as we have all along maintained, a great deal more cinchona in the island than is generally believed, and good prices cannot fail to bring a large quantity to market. The ups and downs which the cinchona bark trade and the cultivation also have undergone of late years, seem now about to settle down into what we trust may be a fairly prosperous state of affairs. The enormous over-production which would have occurred in Ceylon but for the correction of canker has brought prices down to a point beyond which there is no prospect of their receding, whilst the almost complete cessation of planting has brought about a much more healthy state of affairs. With the unit of quinine above 6½ in London it will pay to grow cinchona, and as we have been taught by rude experience that the delicate tree will not thrive in every locality, there is little probability of its being planted where there is not every prospect of its being a success. Those who have a fine cover of cinchona of any age are likely before long to reap very substantial returns therefrom, for the stock of bark in the various trade centres is not large, and manufacturers are by no means well supplied with the article. The first upward tendency is, therefore, likely to set buyers purchasing with a still further stiffening impetus to prices."

The following is a summary of the health, crop, and weather reports for the week ending 31st October, 1885:—
Rain has again fallen throughout the Malabar Presidency, and prospects are improving in all districts. In

will urgently wanted. In Bellary and Anantapore prospects are now favourable. From Mysore the report is also favourable; the standing crops are in good condition, and sowing of rabi and horsegram is general. Except in parts of Kadur and Shimoga, where murrain prevails, the cattle are in a good condition. In Coorg coffee-picking has commenced, and the prospects of the season are good. In Bombay rain is reported from parts of eight districts, but it is still required in places in Guzarat and Khandesh. Reaping of kharif and sowing of rabi are in progress in several districts. In parts of Hind the crops are suffering from want of water and from damage by rats, insects, and storms. In the Berars and Hyderabad the rabi sowings have commenced; the crops promise well. Very little rain is reported from the Central India and Rajputana States. In the former prospects are good on the whole; but in Rajputana rain is needed for the rabi sowings in several places. No rain has fallen in the Central Provinces during the week; but prospects are favourable everywhere, except in Raipore, where rain is wanted. Rabi sowings are in general progress. In the Punjab rain is much wanted in the Jullunder, Ferozepore, and Multan districts for the kharif crops. Rabi operations have commenced in some districts. From the North Western Provinces and Oudh fair weather is reported, but more rain is wanted in most districts. The kharif harvest is approaching completion, and rabi sowings are in progress everywhere. General prospects continue good. In the Lower Provinces slight rain has fallen in almost all districts of Bengal, but little or none in Behar and Orissa. In Bhagalpore, Durbhanga, Hattibagh, and Gya more rain is wanted for the crops. Agricultural prospects are on the whole favourable, except in flooded tracts. In Assam the weather is seasonable and crop prospects good. In British Burmah the crops promise well. Fever is more or less prevalent in all provinces; otherwise the public health is fair. Prices are generally stationary, except in Mysore, where they are falling.

A CONTEMPORARY furnishes the following statistics of the Malt liquor trade of different countries:—

The rapid growth of the brewing industry in the United States is something wonderful. The value of the output has advanced from eighteen million dollars in 1860 to upwards of a hundred millions in 1880. It is estimated that over 3,000,000 gallons of malt liquors are annually brewed in the United States and in Europe, of which Great Britain produces nearly 1,000,000,000, Germany 900,000,000, Austria-Hungary 280,000,000 more, and the United States 800,000,000 gallons. Mr. G. P. Keese, in an article in *Harper's Monthly*, says:—"English brewers are, as a class, the most wealthy of her manufacturers, and much land is passing from its old time owners into their hands. 'That is beer! that is beer!' that is beer! and that is beer!" said a Scotchman recently to an American fellow traveller on one of the Scotch lakes, as he pointed east, west, north, and south to fine estates formerly belonging to old Scotch families. The present Parliament includes fourteen brewers and one maltster. The town of Burton on Trent, the centre of the trade, is one enormous brewery. It includes over thirty great brewing firms, among them those of Bass and of All opp, which, with the great Guinness brewery of Dublin, lead the trade. The firm of Bass alone covers 150 acres with its works, has several miles of private railway connecting them, employs two thousand persons, and produces above 750,000 barrels of beer a year. Nearly a third of the British revenue comes from the excise tax on beer and spirits, the total yield in 1882-84 being upwards of 87 millions sterling. It is hardly to be wondered at that such a fertile source of revenue should have provoked conflicting theories of taxation. M. Leon Say, the French Minister, holds that in taxing ardent spirits legislation should be guided exclusively by fiscal considerations, while Mr. Gladstone is of opinion that "fiscal grounds must necessarily be secondary, and that the question ought to be decided on social and moral grounds." The question is whether taxation should not be framed so as to discourage the drinking of the less wholesome beverages, and the Swiss Statistical Bureau, which is an authority on the subject, replies in the affirmative. Taxation is perhaps the most effectual of all checks on intemperance, and it is perhaps the most effectual of all checks on intemperance, and it is perhaps the most effectual of all checks on intemperance, and it is perhaps the most effectual of all checks on intemperance. Now that the sources of revenue are being looked to more closely, we may expect to see taxation fall more heavily upon some of these native indulgences which have hitherto been granted a dangerous immunity.

There has been some controversy respecting the true origin of the Ceylon Tea enterprise, and Mr. P. D. Millie, writing

from Edinburgh to the *Ceylon Times*, claims to set the matter at rest. He says—

In your overland issue of the 7th August under the head of "Planting Notes, Rambodde, August 3," is the following statement:—"Shortly after the North Panduloya estate was opened, a steep face of the new lands, estimated, I think, at 10 acres, was put into tea, and, in due time, a man from the Sandakunda, a Chinese if my memory serves me, was imported to superintend the making, sent over by a nephew or cousin of one of the proprietors," &c.

This is an error. No one was ever imported to superintend the making of tea. I frequently attempted to make it myself, but failed. The tea I took at was good, but it was nauseous and bitter to the taste, and I gave up the attempt, having nothing to fire it in but an earthen chatty.

On my leaving for England, Mr. Lylford, who was left in charge, was more successful in his attempts to prepare the tea and told me he used it for himself. A small packet of this tea was sent me by him, and on my submitting it to a London broker for his opinion, it was "excellent tea, but badly prepared—spoiled in the preparation."

We were under the impression in those times that the preparation of tea was a subject most difficult to obtain any practical information about, and although we were well aware that it would grow well, yet, what was the use when we could not prepare it? And for any small acreage it was not worth while to import a man on purpose.

It was then even said and believed, that the Chinese kept the mode of preparing tea secret, which they would not make known.

So convinced was I then that tea would grow well in Ceylon, and that the country would eventually grow it very extensively, that I had serious intentions of opening a large tea clearing; but at that time having so much coffee land in course of planting, I had neither time nor labour to spare for tea, which was the reason I was deterred from the further extension of tea, and not as your correspondent states that it was "badly mixed" as I do not remember the tea on North Panduloya having ever suffered from bug.

I may state that the original planting of tea referred to was from seeds of the Chinese species obtained from the Paradisea Gardens, and the Assam species from seeds forwarded from Calcutta by Capt. Reddie. The former made a poor appearance in growth as compared with the latter, which flourished luxuriantly, as if it were in its natural soil and climate, from which I then inferred that the Indian teas would be the proper sorts to cultivate, not the China tea.

More than twenty years ago I knew that Ceylon would at some time be a great tea producing country, but then nobody would give attention to anything but coffee.

We have received a copy of the report on the Cattle and Horse Fair, held at Umritsar in April last. This is one of the largest and most important horse and cattle fairs held in India. The report comes six months after the event; but we are told that the delay in its compilation was unavoidable. The attendance of animals was the largest on record, the total being 22,961 head of cattle, and 5,569 horses, the increase over the total of the previous year being 13,450 head of cattle and 1,500 horses. The attendance, too, at the fair exceeded previous experience, the chief cause of this probably being the brisk demand from the frontier, the Commissariat contractors doing a large business, chiefly in the expectation of the movement of troops in the direction of Afghanistan. Of the total number of animals exhibited for sale, 74,725, or about 80%, found purchasers. The average price per head fell from Rs. 14 0-6 to Rs. 13 11-9, but the total proceeds rose from Rs. 8,15,304 to Rs. 10,36,427. Considering the increased magnitude of the operations of the fair, the Deputy Commissioner does not consider that the falling off in the average is so great as to create surprise. Prizes to the amount of Rs. 2,010 were awarded to 140 animals specified as cattle. Awards to the amount of Rs. 300 were also specially set apart for draught oxen. The income from all sources, for both the cattle and horse fairs, was Rs. 10,460-2-3, against Rs. 8,037-2-3 in the previous year. The expenditure was Rs. 4,944-13-0 against Rs. 4,356-15-2. This increase is, however, only nominal, and is due to an expenditure of Rs. 680 on prizes granted by Government to horses. The amount expended in awards to horses was in addition to that awarded to cattle, and Rs. 1,000 were given for this purpose,

77 animals receiving prizes. These cattle-shows are still in their infancy in India, but the movement is showing great signs of development, and only requires we suspect the impetus that would be given by a more liberal offer of awards, to render it very popular. It should certainly be encouraged all over the country.

We regret we cannot agree with the line of argument taken by Mr. Allen in his letter, which we publish to-day, on the composition of milk, and the relative value of ensilage as a milk-producer. As a distinguished graduate of the Cirencester Agricultural College, his views on agricultural matters are entitled to much weight, and we can hardly say that it gives us much pleasure to hear from him. But as regard to ensilage, we hold entirely different views. As to milk, we may remark that the first milk (colostrum) after calving is not, as a rule, considered fit for human consumption in this country, so far as we are aware. To explain this, it may be stated that ordinary milk is composed of—

Water	87.25
Butter	3.50
Caseine	3.50
Albumen	0.40
Milk-sugar	4.80
Mineral substances	0.75
			100.00

This, of course, varies very considerably—the variations being due to the breed of the cow, the nature of the food, climate, &c. As an instance of this variation, we quote the following table furnished by Professor Sheldon:—

Water	83.65 to 90.00
Butter	1.8 to 5.20
Caseine	3.00 to 5.00
Albumen	0.30 to 0.55
Milk-sugar	3.00 to 5.50
Minerals	0.70 to 0.80

The first milk from the cow contains a superabundance of caseine or curd, and this substance, as is well known, is rather hard of digestion. Irrespective of this, the first milk is not in a state of perfect solution and proportion. Professor McConnell says:—

To understand how milk was produced, it is necessary to have a clear knowledge of the structure of the cow's udder. The mammary gland consists of two halves of highly developed tissue; each half has two teats (the third is abortive), and each teat is literally a hollow bag fastened on to the bottom of the udder. At the top of each there is a cavity, known as the "milk cistern," and from this there ramify tubes in all directions through the substance of the vessels. These tubes grow smaller and finer away from the teats, until at last they end in microscopically small sacks, which are lined with epithelial cells. These sacks are grouped into globules of three to five, and have a common outlet. It is the function of this cell structure to manufacture the milk, or at least the corpuscular part of it. Part of the milk must, of necessity, be simply transuded from the blood through those cells—the water, for instance—as the outside of the globules is thickly lined with blood vessels; but other parts (and especially the butter globules) are manufactured by the living action of the lining cells. New cells are formed behind the old. These are pushed off, and fall into the cavity of the tubes; but before doing so they had the interior metamorphosed into butter particles, the walls disappear, and normal milk is the result. Colostrum, or the first milk after calving, contains a large amount of these cells in an unchanged condition. The activity of these cell structures can be stimulated greatly by proper feeding and general treatment, and the proportion of solids to water increased by rich food, though at the same time the breed and general characteristics of cows have much to do with it.

The words we have italicised will explain our meaning. For the rest, we stated before what our own experience has been.

In respect to ensilage, we have said sufficient to prove its superiority over ordinary fodder in its green state. We do not, however, remember to have said that stock fed on ensilage alone would produce the best results. It is to be understood that corn and other solid food, such as oil-cake, roots, &c., forms part of the diet of stock in addition to silage. We have

consistently maintained that as a means of storing fodder when plentiful against a time of scarcity, the system of ensilage cannot be surpassed; and we have strongly advocated the encouragement and introduction of the system in certain localities in particular, and throughout the country in general. But we are unable to see how "by ascribing higher qualities to ensilage," it will "do more harm than good in the long run."

AGRICULTURE OF FINISTERRE

[By B. C. BASU, Bengal Agricultural Scholar, at the Royal Agricultural College, Cirencester.]

THE agriculture of Finisterre, in common with that of many other parts of Brittany, has been largely influenced by various circumstances, social and physical, of which it is necessary to recount a few important ones. Originally descended from the Teuton race, the Bretons have so long kept the purity of their blood, and the language and manners of their ancestors. Their physiognomy is at once distinguished from that of the Latin race to which the rest of the French belong. An entirely distinct language, and an almost perfect seclusion in the highlands of Brittany have kept them more or less away from the general current of progress in France; even at this day, in spite of the equalizing tendencies of the age, they are regarded by competent observers as at least a century behind in the march of modern civilization. The true Breton house with its curved roof heavily thatched with straw is still pretty common; in the interior, heavy cubical bedsteads with folding doors present a singular relic of olden times. The people are conservatives of the most orthodox type; alike in religion and politics as in agriculture, they are very slow to change. The clergy wield an enormous power in Brittany; the revolution of '93 scarcely affected its pious children. The recent annulment of the Senatorial election of Finisterre has been a violent rebuff to the Breton clergy who had been hitherto manipulating all the political powers of their faithful flock. So long secluded from the general current, the country is at the present time undergoing a series of far-reaching revolutions. It is hardly sixteen years that railways have been extended into the extreme west of France, and already remarkable changes have taken place in the habits of life of the people. Side by side, compulsory service in the army, and compulsory education—a measure of only recent years, will influence in the same direction. Before railways were introduced, the peasants lived an almost totally vegetarian life, tasting meat perhaps once or twice a year on days of high festivity. Their sole ration consisted of, and to a large extent even now consists of, black bread, and a peculiar *crispe* or pancake made of buck-wheat flour. Many peasants do not know how to read or write, not to say that they neither speak nor understand the French language. In a few years, however, a new generation will rise, who shall have no such difficulties; all the evils of circumscription and seclusion will thus steadily disappear. The price of labor has risen a good deal in these latter days; with all that, however, it is 15d. for man, 10d. for women per day—scarcely half of what a laborer earns in other parts of France.

I have already sketched the leading physical features of Finisterre. It remains for me now to say a few words on the way in which some of them bear on the agricultural enterprise of small peasants. In walking through any part of Finisterre, one meets with cultivated fields as often as with broad expanses of heath. All high altitudes along the eastern border of the department, the tops and sides of hills are alike but vast sheets of heather, broom and fern. These are occasionally relieved by small patches of meadow, or fields where buckwheat or rye may be struggling with ferns which are the natural herbage of the soil of the district. A totally different order of things is visible along the sea coast. There a very superior nature of cultivation prevails; along the sea coast I have seen some of the most splendid crops of wheat and oats that I recollect to have seen in France on elsewhere. The peasants seem to be in much easier circumstances; they have no longer to contend for the mastery of their fields with ferns or impenetrable in other parts. They use large quantities of sea-weeds to manure the fields; these decompose rapidly, and when duly mixed with home made manure, do not fail to yield abundant harvests.

Between the sea coast and the eastern border of Finistère, is the region of middle altitudes from 300 to 400 feet above the sea. This includes Lézerdeau. The order of things here is midway between what it is in the districts described above. While extensive fields and meadows are quite common, there remains a good deal of waste yet to be reclaimed from the wild state.

It may be now asked what prevents the reclamation of such lands? To this it may be simply replied that the difficulties are so immense that a good deal even of such as have been already reclaimed is far from being so in the real sense of the term. I have previously stated that according to chemical analyses some soils in the neighbourhood of Lézerdeau show an amount of acidity which is stupefying. Acidity of soil is always fatal to the growth of crops; it must be neutralized in any case before successful cultivation may be at all possible. To destroy the acidity of the soil, we have two means. The first consists in employing and incorporating with the soil such a quantity of lime—either as carbonate or phosphate—as corresponds to the degree of acidity. On the soils above-mentioned, fully 50 tons of carbonate of lime would be required to attain this end—which means a prodigious expense of no less than £80 per acre. Such a measure is clearly outside the dream of even the richest proprietor. The second means consists in helping the oxidizing action of the air by frequent deep stirrings of the soil—as well as such means—as weeding, draining, etc. In either way capital lies at the root of the question: the problem of reclaiming or amelioration of poisoned soils resolves itself into one of capital. The question of capital presents two important aspects in relation to the *petite culture* of France. In the first place it passes for an axiom that the amount of relative capital—i.e. capital sunk per acre of soil cultivated—is much more considerable in the case of small properties than in that of larger ones to be equally effective in either case. Thus, while a farm of 100 acres can be well cultivated (say) with a capital of £10 per acre, it is next to impossible to cultivate in the same way one of 20 acres, even with a capital of £20 per acre. Capital is much less effective in small properties, simply because it does not find its full sphere of action.

In the second place, the French peasant, even supposing him to have sufficient capital at hand, instinctively prefers to sink it in the purchase of land, rather than to employ it in ameliorating what he already has. This great evil—the “demon of property” of French economists—undermines the very foundation of all agricultural improvements. While capital is minimized for the cultivation of the soil, it is pushed to its maximum in its purchase: land not worth 25s. an acre elsewhere, often sells for 5,000 francs a hectare, i.e. at a fully 60 years’ purchase! Such sales are only possible in small parcels, in order to be within the reach of the largest number of competitors for the purchase; large properties are thus disposed of in this way with great benefit to their owners; a practice which still further aggravates the evils of land “dissection,” as it has been termed. This intense thirst of the French peasant for increasing and “rounding the corners” of his little property results from the social constitution which has risen out of the French law of heritage. All property being equally divided among the children, it is quite natural that the peasant, whose occupation is at any time too small, should be anxious to augment it, so that he may leave enough to every child on his death.

To return to Brittany. Although extensive culture is all but unknown among the small proprietors, yet here and there, cases are found in which the cultivators have made some attempts towards it, and obtained good results too to boot. An instance of this kind is found in the person of a very enthusiastic peasant named Pilorger, in the vicinity of Quimper. I went to see his property one day in company of Monsieur Vland, Professor of Agriculture at Lézerdeau. It consists of about 30 acres—a great portion of which the owner has reclaimed for himself, from ferns and heather at considerable expense. Monsieur Pilorger enjoys a well-merited reputation in his district for his potatoes. After having experimented with 30 different varieties of potatoes, he has arrived now to choose three or four which give him the best results. One of these,

it may be mentioned, is the *magnum bonum*, so favourably known in England. His pastures and fields are heavily manured every second year with farmyard manure which he enriches with nightsoil obtained at Quimper; their produce is far superior to the average of the country. It may be stated by the way that night soil is pretty frequently used in Finistère, as well as in many other parts of France, but its use is by no means general. Apart from the prejudice against it, it requires a good deal of special tools and carriages, &c. for its utilization. Monsieur Pilorger is also a good breeder of the native Breton cattle; recently a new book has been established of the breed; several of his cows have been entered into the book, and a bull and a cow of his obtained the first prizes in the last Breton show at Brest. Though a peasant, he is well-instructed, reads the important *Agricultural Journal*, and thus closely follows the precepts of modern agriculture, and no doubt to these he owes his success.

The condition of the smaller class of peasants is anything but enviable. The average size of occupations is barely 3 hectares (7 acres). These, with soil so handicapped by nature as described before, offer at best a very meagre subsistence. All the evils of land division have been exaggerated in Finistère. Elsewhere industry and emigration carry away the surplus of the peasant population, and thus prevent to some extent excessive pulverization of land. That land has been more minutely divided in Finistère than in many other parts of France is at once evident in the relative sizes of fields. These are often ridiculously small in Finistère; on one field hardly an acre in extent, I counted four distinct crops growing side by side, viz., buckwheat, oats, potatoes, and clover. The size of the entire property of the owner may be easily imagined. The ignorance of the Breton peasant prevents him from going far in quest of more remunerative employments; when he has not sufficient land to occupy all his time, he has to rest content with the 12d. or 15d. of wages, which he can earn by day work. Rather cleanly in appearance, his dwelling, however, often presents the most filthy appearance. Pigs and poultry may be seen grazing alike in the yard as inside the house; all the filth and muck of the manure heap outside being drawn, so to speak, to the very foot of the bedstead. His destitution is often painful to behold. From what I have seen since then in the south of France, my ideas as to the relative easiness of peasant-life have almost entirely changed. In the south, as I shall have occasion to speak of in later reports, the dwellings of the peasants, and the amount of comforts inside them leave nothing to be desired. In Brittany, the state of the peasants is often very disappointing. Beggars abound everywhere. From the railway station to the town of Quimper, within a distance of a mile, one can certainly count upon meeting at least half-a-dozen of half-starved creatures. In fact the prophecy of MacCulloch has been so far verified in the case of Brittany, when in the year 1833 he wrote: “In half-a-century France will have become the great pauper-warren of Europe.” Happily, we have reason to believe quite otherwise in regard to the other parts of France. Beggings, however justifiable it may be in particular cases, is always liable to carry in its train results of a demoralizing nature; it has not failed to do so in Finistère. Very often boys and girls are made to beg, though apparently in easy circumstances, and often stout robust fellows would not hesitate to step beside on the road to beg for a penny. I was deeply affected with the extraordinary amount of beggary I saw in Finistère, but have been since greatly relieved to see a happier order of things in the south.

The peasants of Finistère have profited very little by modern inventions and the teachings of scientific agriculturists. In rare cases the old heavy wooden-beamed plough has been abandoned for modern ploughs; the primitive butter-churn, which consists of a wooden or earthen-ware jug fitted with a vertical piston and a horizontal disc, is still pretty common in these extreme western parts of France. With few exceptions, the husbandry is still the same as it long has been. In the conservation of manure, the peasants show singular ignorance of details. They have long learnt the use of lime by experience; happily for them, vast accumulations of calcareous sand occur along the coast of Finistère; it is composed of the comminuted debris of marine shells, &c., and contains generally from 45 to

60 per cent, and often as high as 80 per cent, of carbonate of lime. The expenses of carriage are heavy when it has to be carted long distances. At Quimper, which is about 7 miles from the sea, it sells for about 4d. a cwt. The use of phosphatic manures is one of the lessons the peasants of Finistère have learnt from the teachings of agriculturists. The soil being usually acid, the neutral tricalcic phosphate is invariably preferred to the acid super-phosphate of lime.

A few words should be said on the live stock of the district. Brittany enjoys a very wide reputation for its cattle and horses. The Breton cow is indeed remarkable in many points. A veritable titmouse, she lives on very small quantities of food, often of a very inferior quality; with this she yields milk which is like extraordinary in quantity and quality. On an average, she gives 300 gallons *per annum*—~~half of the~~ yield of average shorthorn cows, though she is hardly a quarter the size of the latter. While on the other hand, her milk yields 25 per cent of cream, which is astonishing when we consider that the richest milk of the Jersey scarcely gives 20 per cent. She is very sure of foot, and thus well adapted to grazing on steep hill sides. Her condition in Finistère can, however, be hardly envied. She suffers in common with the general agriculture of the district. The poorer peasants have not food enough to maintain their beasts. They are very often tethered on road-sides, or on margins of corn fields, where they pick up, as best they can, any grass that may straggle among the ferns. It is marvellous how they live on such scanty fare; but it is not the less certain that their stunted form is only the result of insufficient nourishment. With better nourishment, they do not fail to increase in size, as is very evident in the little herd of Monsieur Pilorger, whom I have named before. At Quimper, there is a very large market of cattle which meets every Friday; an enormous number of cows is here sold off for exportation to different parts of France. A good deal of shorthorn blood has been lately imported into the breed; with shorthorn crosses, the cows attain much larger size and yield more milk, though the latter deteriorates a little in quality. A few years ago, Ayrshire bulls were in great demand for crossing, but the results having been very disappointing, and the practice has been entirely abandoned.

The Breton horse enjoys perhaps a wider reputation than the cow. It is largely sought for from all parts of the country. Rather light in form, it is admirably adapted for all farm work, while often it trots well at the cart.

Brittany has a peculiar breed of white pigs of about the size of middle Yorkshires. It has never been improved; the enormously long heavy head, high legs, and large flapping ears of the Breton pig show it to be rather akin to the wild pigs which graze on the shores of the Highlands of Scotland. Brittany has very fine sheep, a black breed is sometimes met with; these live by browsing among heather at high altitudes.

IRRIGATION ON THE SCHOOL FARM AT LEZERDEAU, FINISTERRE.

[By B. C. BASU, Bengal Agricultural Scholar at the Royal Agricultural College, Cirencester.]

THE school of irrigation and drainage at Lézerdeau is an intermediate agricultural school, and belongs to the category of *Écoles pratiques*, of which there are several in France. It is, however, much superior to its fellows on account of its speciality in irrigation and drainage, as its name implies. Of the school itself, I have very little to say; the system of education is almost the same as at Grignon; theoretical studies may not be so deep, but practice in everything is rigorously insisted on. As regards irrigation and drainage, the teaching is here more complete than elsewhere.

Monsieur Baron, the Director of the School, is at the same time the tenant of the farm itself; he has also rented two adjoining farms, and the three together form a compact occupation of about 250 acres. It is, however, on the school farm that meadows have been laid down to irrigation. Before describing its practice in detail, it will be better to glance at the aspects of the country, its soil and climate, as these bear very largely on irrigation.

The country about Lézerdeau partakes of the characteristic mountainous nature of Finistère. Flat table-lands, more or less extensive, are split through by deep gorges often with almost perpendicular sides; the excess of rains which have fallen on the uplands collects into narrow brooks which rush impetuously along the bottom of the valleys. The whole landscape is, indeed, that peculiar to primary formations. The base of the soil is granite, intercalated with very extensive veins of quartz and amphibole. It is sandy or clayey according as quartz or felspar was the predominating factor of the granite from which it has been formed. On the school farm, the soil is almost of a very light sandy nature, and rests on a bed of impervious clay. The soil of the locality is usually very deep, unless on the steep flanks of valleys, or where otherwise exposed to considerable washings. Chemically, the soil is unusually rich in potash, derived from the original granite; on the other hand it is naturally almost wholly destitute of two other elements in which primary rocks generally fail, viz., lime and phosphoric acid—substances indispensable to plant growth. The consequence is that agriculture is impossible without treating the soil with considerable quantities of lime and phosphatic manures; in its normal state, the soil supports only dense growths of ferns, heather, and broom. These latter die and decompose, and thereby give rise to an unnatural quantity of acid substances in the soil. From analyses made at the laboratory at Lézerdeau, it appears that on some soils in the neighbourhood of the school, fully two per cent of carbonate of lime would be required to neutralize their acidity. This, when put into proper figures, means an addition of 50 tons of limestone per acre for the first 10 inches of the soil. This fact has an enormous bearing on the agricultural enterprize of the district, and I shall have occasion to speak of it later on in its connection with the *petite culture* of Finistère.

From its vicinity to the sea, the climate of Finistère is very temperate; being directly exposed to the moist south-westerly winds from the Atlantic, it is moist and cloudy. The rainfall averages about 40 inches *per annum*. Unlike the South of France, droughts are unknown here, and consequently irrigation has much less significance in Finistère.

The system of meadow irrigation at Lézerdeau is known as *irrigation par simple déversement*. In England it is known as the catch-meadow or hill-side irrigation; it finds a very limited place, however, in British agriculture. It is only possible, as its name implies, on the side of hills, or on lands having a sufficient slope. The source from which water is derived most commonly is springs, as at Lézerdeau; sometimes brooks, common enough in hilly districts, are perfectly adapted to being utilized for watering the lower slopes. The geology of Finistère with its alternating beds of sand and clay, broken through by quartz veins, &c., is particularly favourable to the growth of springs. These either come up to the surface or as is most commonly the case, lie underground, where they betray their presence by a green moist appearance of the herbage above them, or very often by growths of rushes, sedges, and various other semi-aquatic plants. The manner of utilizing these springs, when once discovered, is very simple. At Lézerdeau, the springs are very shallow, probably not deeper than the first layer of sub-soil clay; they debouch mostly at the surface; when underground, they have been tapped by digging into their hearts. The issuing water is collected in a reservoir in the neighbourhood, often immediately over the springs. The construction of such reservoirs is very simple; at Lézerdeau, however, the State has gone to considerable expense to give them more durability than is usually their lot. The principle in any case is the same as will be seen in the diagram appended to the report (Fig I)*. It represents the position of a watershed with its primary rigoles which carry away the waters to be distributed over the meadows. The dotted colour lines show the respective altitudes of different parts of the land. It will be seen that the right portion of the land at the top has more slope than the corresponding portion on the left side. Such failures of slope on hill-sides favour the growth of mosses, which often degenerate into bogs or marshes—phenomena not very unfrequent in hilly districts. To render such land arable, it has to be drained, as shown in the diagram. The main drain

* We have not published the diagram.—Eds. J.A.

debouches into the reservoir, and so far it plays the part of a spring. Besides this, two springs have been shown at higher elevations; they have been tapped and their water led into the general reservoir. Three other springs have been represented on the bottom of the reservoir; these form the main sources of supply. As to the construction of the reservoir, it consists simply in barring across the face of the valley, as is apparent from the figure. Some care is necessary in the building of the embankment in order to make it water-tight—a task which is not always easily or satisfactorily performed. At Lézardeau, all embankments have been made of solid masonry, regardless of all expenses which such a luxury would entail. But where economy and not luxury has to be studied, it would answer equally well to build them with ordinary materials found on the spot, taking care, however, to put always a certain thickness of impervious puddle in the interior of the barrage. In all cases the foundation of an embankment should always lie in an impervious stratum, however deep it might be necessary to dig to get into it. The primary rigoles originate at the lowest part of the reservoir; the delivery is regulated by a *vanne* or sluice on the side of the embankment. (An elevation and section of a *vanne* of this kind in use at Lézardeau are given in the plate appended to the report.) Above the primary rigoles, two smaller rigoles may be seen; these are mostly unnecessary, their only function being to water the strip of land which lies between themselves and the primary rigoles. A certain slope is always necessary in the rigoles to facilitate the flow of water, it is usually .002 in the primary rigoles; but the slope varies according to the dimensions of the rigole as well as the object it is intended for.
